found of value. Ten per cent calcium gluconate, 5 c.cm. intravenously or intramuscularly every 2 or 3 days, 1 c.cm. of colloidal calcium with vitamin D intramuscularly every day, or calcium thiosulphate may be used. Ascorbic acid is also said to help. This condition must be distinguished from symptoms of abdominal infection and the patient must be particularly advised not to swallow sputum.

Dermatitis  (1) Exanthematous.
(2) Enanthematous.
(3) Nine-day erythema.

A very distressing generalized dermatitis may be found which may be of any type but is usually exfoliative. This is an absolute indication of suspending gold therapy forever. The patient must be kept in bed and sodium or calcium thiosulphate should be administered as well as calcium by mouth and hypodermically.

Small patchy areas may sometimes appear which may be a warning signal of an oncoming generalized dermatitis. Here also the same form of treatment will hold good, but before reinstating gold therapy one must be perfectly satisfied that the condition has thoroughly disappeared. The dose must be very small and preferably intramuscular.

In cases of very distressing symptoms local application of calamine lotion and a warm saline bath will be found very useful. Sedatives must be given and a brisk saline draught should be prescribed. Morphia may have to be used as a last resort.

Freund recommends a preparation called asthomolysin made up of adrenaline and pituitrin which he claims will quickly cure the eruptions and the irritation will almost immediately disappear.

Hyperidrosis.—Generalized hyperidrosis or bromidrosis may sometimes make their appearance. The former has been described as a grave symptom and a warning signal of a graver consequence by Heaf, who recommends complete suspension of gold therapy in such cases.

The patient must be put to bed under the fan and $\frac{1}{2}$ c.cm. of 1 in 1,000 adrenaline solution with atropine of 1/200 should be given hypodermically. A spray of cold water on the face and a dose of a stimulant will be of great help.

Joint pains sometimes make their appearance but this is only temporary and may be disregarded. They are relieved by local applications and rest.

Metallic taste in the mouth is a very distressing symptom; liberal glucose drinks may help.

Biotropism is exacerbation of latent foci; this is rare with gold. The commonest reactions are—nine-day erythema; transitory diarrhoea and colic; gold influenza; neuralgic pains; herpes zoster; various inflammatory reactions local or elsewhere including bronchitis and conjunctivitis.

In these cases gold should be suspended for the time being and ordinary treatment of fever

(Continued at foot of next page)

H & O AGGLUTININS IN CHOLERA PATIENTS

By C. L. PASRICHA

MAJOR, I.M.S.

D. N. CHATTERJEE

and

B. M. PAUL

(From the Cholera Bacteriological Enquiry, Indian Research Fund Association, School of Tropical Medicine, Calcutta)

THE development of agglutinins for *V. cholerae* in cholera patients has been recorded by a number of workers. Greig (1914) examined the blood of 363 cholera patients and found that in a few cases cholera agglutinins had developed as early as the second day of the disease but this was exceptional. The specific agglutinins were well marked on the sixth day of the disease and the titre remained high from the sixth to seventeenth day. A drop occurred in the agglutination curve on the twentieth day. The titre varied from 1 in 40 to 1 in 1,000. Agglutinins were absent in the majority of the fatal cases of cholera. In cases in which both *V. cholerae* and inagglutinable vibrios were isolated, agglutinins were developed only against *V. cholerae* and not against the other vibrios. These findings have been corroborated by subsequent workers.

In view of the recent work on the antigenic structure of *V. cholerae* it was thought desirable to study the development of the 'H' and 'O' agglutinins in cholera patients. The blood from 175 cholera patients was examined. Agglutination test was put up in Dreyer's tube using a

(Continued from previous page)

with alkalies, neuralgia with aspirin and salicylates, abdominal pain, colic or diarrhoea with belladonna and calcium should be adopted. If the symptoms have been absent for 24 hours lower intramuscular doses may be adopted.

Jaundice is a grave symptom. Liberal use of glucose will cure the condition but gold therapy must be entirely suspended.

Minor symptoms but by no means negligible and which demand suspension of gold therapy altogether are sleeplessness or undue sleepiness, lassitude and a continued sinking lazy feeling.

I always support my cases undergoing gold therapy by sanatorium measures, artificial pneumothorax, phrenic evulsion, oleothorax, gelatinothorax, according to the special indications of individual cases. I have followed a few hospital cases of thoracoplasty supported by various forms of chrysotherapy and the results have been uniformly encouraging.

formolized (0.2 per cent) suspension of a young agar culture as the H antigen and a boiled suspension in saline as the O antigen. Alcohol-treated vibrios or vibrios suspended in 0.5 per cent lithium chloride were not as satisfactory as the boiled suspension. Final readings were taken after 18 hours in a water bath at 55°C.

The results of the agglutination test and the bacteriological findings are given below in tabular form.

From tables I and II it will be seen that:—

1. Cholera agglutinins are not demonstrable during the first three days of the disease.

2. On the 4th day cholera agglutinins are found in half the number of patients examined.

From the 6th day onwards agglutinins are present in increasing numbers of patients.

3. The development of H agglutinins is earlier and to a higher titre than of O agglutinins.

TABLE II

Showing the number of cholera patients (bacteriologically proven, non-fatal) examined on different days of the disease and the number and percentage in whom cholera agglutinins (H & O) were found

Days of disease	Number of cases examined	Number showing cholera agglutinins	Percentage showing cholera agglutinins	
			H	O
1st	19	0	0	0
2nd	13	0	0	0
3rd	17	0	0	0
4th	8	4	50	12
5th	8	4	50	37
6th	10	5	50	50
7th	13	8	61	46
8th	20	18	90	55
9th	24	18	71	60
10th	23	17	74	57
11th	9	8	90	66
12th	11	9	81	73

4. There are certain bacteriologically proven non-fatal cholera patients, who do not show agglutinins for the standard cholera strain Inaba. This is more marked in cases of O agglutinins and is well seen in table III in which are recorded the results of examination of 61 patients in whom agglutination tests were put up with the Inaba strain and with the homologous strain. Only those cases in which agglutinins were present for the homologous strain are included in this table. Agglutinins for Inaba were absent in 11 (or 20 per cent) of this series.

In patients from whom Ogawa strains of *V. cholerae* were isolated the agglutinins are most marked for the homologous strains. The few anomalous results are explained by the fact that in a number of cholera patients both the Inaba and Ogawa types of *V. cholerae* were found.

In nine patients agglutinins (mainly H type) were found for the Inaba strain and no agglutinins for the case strains. These are shown in table IV. No satisfactory explanation can be advanced for these findings.

The development of agglutinins in patients in whom *V. cholerae* and inagglutinable vibrios were isolated is shown in table V. It will be seen that in bacteriologically proven cholera cases (table V) agglutinins for *V. cholerae* were found in the 7 patients examined on the 8th and 10th day of the disease. In one patient H agglutinins in a titre of 1 in 20 for the homologous inagglutinable strain were present on the first day of the disease and in another patient H agglutinins (1 in 80) were present on the 8th day of the disease. The first case can be disregarded and the second is of particular interest as the inagglutinable vibrio from the case

(no. 821) shows H relationship to *V. cholerae*. In patients in whom inagglutinable vibrios only were isolated, agglutinins were not demonstrable for the homologous inagglutinable strain. In 3 of the 8 patients examined on the 7-10th day of the disease cholera agglutinins were found, demonstrating that infection was probably due to *V. cholerae*.

In clinical cholera patients from whom vibrios were not isolated agglutinins for *V. cholerae* were found in 5 of the 20 examined on the 7th and 9th day of the disease (table VI). These are undoubtedly cases in which the infecting

organism was *V. cholerae*. The 15 cases in which cholera agglutinins were not found probably included a certain number of cases not of true cholera.

(Continued at foot of next page)

TREATMENT OF PERITONSILLAR ABSCESS

A NEW METHOD

By K. KRISHNA RAO, B.Sc., M.B., B.S., M.R.C.P. (Edin.),
D.L.O. (Eng.)

Ear, Nose and Throat Specialist, Krishna Rajendra
Hospital, Mysore

PERITONSILLAR abscess, or quinsy, is the result of inflammation due to septic infection in the tissues adjoining the tonsil. The infection reaches the peritonsillar tissues from the infected crypts of the tonsil, which get blocked either partially or completely after recurrent attacks of acute or sub-acute follicular tonsillitis. Similarly the 'intra-tonsillar recess' or the 'supra-tonsillar fossa' very occasionally may get blocked on account of adhesions between the plica semilunaris and the enlarged tonsil during an acute attack, and favours spread of infection towards the antero-superior part of the tonsil. This explains the very great frequency of quinsies situated antero-superiorly to the tonsil, and their great tendency to recur. As explained above, however, infection may travel from any of the crypts and so quinsies at the level of the middle third and the lower third of the tonsil fossa are not infrequent.

Regarding treatment, it is very doubtful if such conservative measures as giving tincture of aconite (one minim every hour), or sodium salicylate in ten grain doses or one-sixteenth grain of tartar emetic with two drachms of liquor

(Continued from previous page)

Summary

(1) From a study of a series of cholera patients it has been shown that cholera agglutinins develop on the 4th day of the disease and are found more frequently and in higher dilutions by the 7th day.

(2) H agglutinins appear early and in larger percentage of cases than O agglutinins.

(3) Agglutinins are better developed for the homologous strain than for the standard *V. cholerae* (Inaba).

(4) In a few patients H agglutinins develop for the standard strain of *V. cholerae* and not for the homologous agglutinable strain.

(5) In mixed cases, i.e., passing *V. cholerae* and inagglutinable vibrios or in cases passing inagglutinable vibrios only, agglutinins were demonstrable for *V. cholerae* and not for the inagglutinable strains.

(6) In patients in whom vibrios were not isolated, agglutinins for *V. cholerae* were found. This stresses the importance of serological test in the retrospective diagnosis of cholera in those patients in whom *V. cholerae* has not been isolated during the acute stage of the disease.

Greig, E. D. W. (1914). *Indian Journ. Med. Res.*, Vol. II, p. 733.

ammonium acetate every two hours, in addition to local painting with argyrol, silver-nitrate or guaiacol in almond oil can ever abort an attack of quinsy. By the third or fourth day, when the quinsy is well established, as evidenced by congestion and œdema of the faucial pillars and the uvula, tender cervical glands and general toxic condition of the patient, the best procedure is surgical interference, in addition to such helpful measures as prompt evacuation of the bowels, rest in bed, fluids in plenty, fomentations locally and good nursing. 'Prontosil' and allied preparations are very efficacious as a supplement to surgical interference.

The surgical interference recommended by most British authorities is to drain the quinsy through the soft palate at a site slightly medial to the mid-point between the base of the uvula and the last upper molar tooth on the affected side. They all recommend removal of the septic tonsils during the quiescent interval after an attack, to avoid recurrence.

The drawbacks of the procedure are:—

- (1) It is only a longstanding abscess in the upper third of the tonsil fossa that can be drained by this palatal incision. Even in such cases, the incision drains the abscess at its upper pole instead of at the dependent pole and frequently needs re-opening.
- (2) An abscess in the mid-third or the lower third of the tonsil fossa cannot be drained by this incision and the patient will have to endure considerable discomfort for a long time before the usual palatal incision can afford relief.

In this type of case, as an emergency measure, a small incision may be made at a centimeter from its free border through the anterior pillar at the level of the middle third or the lower third of the tonsil fossa (depending on the site of the abscess) and a curved sinus-forceps gently thrust in backwards and laterally to drain the abscess.

- (3) It is very rare to find a patient coming back for tonsillectomy during the quiescent period and most probably, the patient will be seen by the doctor only with a recurrence of quinsy.

Because of these various draw-backs, many continental authorities, notably Canuyt (1934), Schroeder (1936) and some British Surgeons recommend and practice immediate tonsillectomy as a satisfactory treatment of quinsy. Tato (1933) has collected a total of 356 cases of peritonsillar abscess treated by immediate tonsillectomy, in recent years, including 29 cases of his own. There were no serious complications in any of the cases. His results are reported to have been excellent, providing a safe and quick cure of the abscesses and eliminating relapses with their possible complications. Dr. Linck of the Greifswald clinic (1932, 1934 and 1936) has treated nearly three hundred

cases of peritonsillar abscess with immediate tonsillectomy and his results have been very satisfactory. He observes that the operation is surprisingly easy since the tonsil is partially detached from its bed and the after-pain is much less than that of interval tonsillectomy.

I have so far performed tonsillectomy on both sides, in sixteen cases of quinsy, during the acute or sub-acute stage, under local anaesthesia, with very satisfactory results. Some typical case-histories are given below. It is very gratifying to note that :—

(a) *Hæmorrhage* either primary or secondary rarely occurs from the abscess side.

(b) *Pain* after the operation is more often felt on the healthy side than on the abscess side.

(c) *Septicæmia* did not develop in any case.

(d) Tonsillectomy can be safely performed either at the time of opening the abscess or, if the patient cannot open the mouth widely enough, two to five days after draining the abscess. In either case, the results are uniformly good.

I draw the above conclusions with great caution and reserve, since the number of cases under my care has been very small.

Case I.—A girl, aged 15 years, previous history of frequent 'sore throat'. Admitted on 20th March, 1938, with history of severe pain in the throat and dysphagia of four days' duration. Temperature 101°F. and pulse 110 per minute; fair volume.

Local examination.—21st March. Quinsy left side; left tonsillar gland very painful and enlarged; drained through the palatal incision and a small quantity of foul pus evacuated.

22nd March. Patient's condition very much the same as on admission. Severe pain in the throat and dysphagia present in spite of re-opening the previous incision. Temperature 101°F. Pulse 115 per minute.

24th. Both the tonsils removed under local anaesthesia. The left tonsil was separated very easily from its bed which presented a dark, irregularly granular surface. There was practically no bleeding from the left side at operation.

25th. About two ounces of blood from the right side and the tonsil fossa was found filled with clot. The clot was cleared and an adrenalin plug applied. Temperature 101°F.

26th. Dysphagia much improved. Right side is more painful than the left. Temperature 100°F.

29th. Patient discharged cured.

Case II.—A merchant, aged 25 years, admitted on 20th June, 1938. No previous history of sore throat. Present complaint, excruciating pain in the throat on swallowing during the past four or five days. Cannot talk well nor open the mouth widely. Temperature 101°F.

Diagnosis.—Bilateral quinsy.

21st. Abscess opened on both sides through palatal incisions and pus drained. Prontosil 5 c.cm. intramuscularly. Temperature 101°F.

22nd. Prontosil 5 c.cm. intramuscularly. Temperature 100°F. Pain in the throat marked; dysphagia severe.

23rd. Bilateral tonsillectomy under local anaesthesia. Tonsils were separated very easily from their beds. No bleeding. Temperature 99°F. at 4 p.m.

24th. Pain and dysphagia much improved, can open mouth well. Temperature 99°F.

25th. Can swallow milk and soft bread easily.

30th June. Discharged cured.

Case III.—A tailor, aged 28 years; admitted on 24th June, 1938, 6 p.m. Previous history of nearly twenty

(Continued at foot of next column)

THE INTRADERMAL TEST AS AN INDEX OF VITAMIN-C NUTRITION

By SACHCHIDANANDA BANERJEE, M.B., M.Sc.

and

B. C. GUHA, Ph.D., D.Sc.

(From the University College of Science, Calcutta)

ROTTER (1937) has suggested an intradermal test for the estimation of the level of vitamin-C nutrition of the body. He has observed that

(Continued from previous column)

attacks of sore throat during the last 14 months, each attack lasted three or four days. One attack of left-sided quinsy about ten months ago.

Present history of severe pain in the left side of the throat for five days; dysphagia fairly marked. Can talk well.

Local examination.—Left quinsy discharging through a crypt near the lower pole. Left tonsillar gland painful and much enlarged. No oedema of the epiglottis or ary-epiglottic folds. Temperature 101°F.

25th. 9-30 a.m. Bilateral tonsillectomy performed under local anaesthesia. Temperature 99.5°F.

26th. Patient's condition satisfactory. Can open the mouth quite well and swallows liquids with fair ease. Temperature 99°F. Discharged cured on 1st July, 1938.

Case IV.—A Mohammedan, aged 28 years; admitted on 30th January, 1939. Mother of three children. History of frequent sore throat for two or three years. Had an attack of quinsy on the left side one year back. Present history of severe pain in the left side of the throat and marked dysphagia for five days. Clinical diagnosis of quinsy—left side, confirmed by aspirating 1 c.cm. of frank pus through anterior pillar. Temperature 101°F.

31st January. Bilateral tonsillectomy under local anaesthesia. Practically no bleeding from the left side. Temperature 101°F.

1st February. Pain much less than before operation, especially on left side. Temperature 99°F.

3rd. Only slight pain on swallowing.

4th. Swallows bread and milk with fair ease.

5th. Discharged cured.

In view of the fact, that 'quinsy' patients rarely think of going back to the doctor to have their tonsils removed when they are well and free from pain, it is certainly in the best interests of the patients to remove their tonsils during the acute condition, especially since the method is quite safe, easy, and certain in its results.

It is a pleasure to acknowledge gratefully the encouragement given to me in my work by Dr. J. F. Robinson, the Durbar Surgeon and Medical Officer, Krishna Rajendra Hospital.

when a small quantity of the dye 2 : 6 dichlorophenol indophenol is injected intradermally the colour of the dye disappears gradually. The time taken for the vanishing of the colour is stated to be dependent on the ascorbic-acid content of the skin and is related to the vitamin-C status of the body. It has been observed that if ascorbic acid is injected into an individual the time of decolorization of the dye becomes less. The time taken is much prolonged in patients suffering from vitamin-C deficiency. According to him, if the decolorization time be less than five minutes the individual is saturated with vitamin C. When the time taken is between five and ten minutes the individual is said to be normal and if it is more than ten minutes the patient is considered to be suffering from vitamin-C deficiency.

Portnoy and Wilkinson (1938) have supported Rotter's suggestion. They have examined a series of 103 patients and have found correlation between the blood ascorbic-acid level and the decolorization time.

We considered that the validity of the skin test could be examined with guinea-pigs, where ascorbic acid could be administered under controlled conditions and its effect on the time of decolorization noted. A series of guinea-pigs was therefore placed on a scorbutic diet and the time of decolorization and the change in body weight were followed. Similar observations were taken when a known supplement of ascorbic acid or a mixed normal diet was given to the animals after a period on the scorbutic diet. A remarkable correlation between the change in body weight and the decolorization time was observed.

Experiments were also carried out with three groups of guinea-pigs placed on a scorbutic diet, which was supplemented by different doses of ascorbic acid in the different groups from the start of the experiments. Observations on the decolorization time in these three groups were taken.

With a number of human subjects the urinary excretion of ascorbic acid and the decolorization time of the skin test were noted before and after administration of a definite dose of ascorbic acid. Subsequently, intradermal tests were carried out with a number of Bengali young men, mostly students, to find whether their decolorization time falls within normal limits.

Experimental

The technique of intradermal test adopted was that of Portnoy and Wilkinson (*loc. cit.*). The dye solution was prepared by dissolving 20 mgm. of 2 : 6 dichlorophenol indophenol in 49 c.cm. of freshly-boiled distilled water. The solution was taken in a sterilized rubber-capped phial which was wrapped in black paper and kept in a refrigerator. The dye solution was freshly prepared at intervals of ten days. A 'record' tuberculin syringe with metal piston was used. We preferred the V2A hypodermic needle

no. 16 to intradermal needles. 0.01 c.cm. of the dye was injected intradermally in the forearm of the human subject. The part selected for injection should be free from veins and hairs. In the case of guinea-pigs the dye solution was injected into a part of the shaved abdomen.

A. Decolorization time and change in body weight of guinea-pigs on a scorbutic diet before and after supplementing with ascorbic acid

Twenty normal healthy guinea-pigs of weights varying from 205 g. to 567 g. were taken. They were placed on a scorbutic diet containing ground oats 80 parts, ground gram 20 parts and salt 1 part. 50 c.cm. of milk autoclaved at 15 lb. pressure for 30 minutes were supplied daily and 1 c.cm. of cod-liver oil was given twice a week. Intradermal tests were performed on the shaved abdomen at intervals of one to three days, and their weights were recorded. At the beginning

Fig. 1.

Fig. 2.

of the experiment when the body of guinea-pigs were not depleted of vitamin C the time of decolorization did not correlate with the weight, but when they were

gradually developing scurvy their weights began to fall and coincidentally the time of decolorization in the intradermal test gradually lengthened. In guinea-pigs which were allowed to

Fig. 3.

die of scurvy the intradermal test time varied from 2 minutes 30 seconds to 4 minutes 10 seconds just previous to their date of death (figures 1 to 3). To some of the guinea-pigs,

Fig. 4.

when they developed scurvy, either normal diet containing germinating gram and green grass was given or a dose of 4 mg. to 8 mg. of ascorbic acid in addition to the scorbutic diet was administered

daily. As the animals recovered they gained in weight and the time of decolorization diminished. When they attained their former weights they were again placed on scorbutic diet.

Fig. 5.

Their weight continued to increase for some time, which was followed by decrease in weight. The time of decolorization varied inversely with

Fig. 6.

their weights. Figures 1 to 3 show the weight and the decolorization curves on a scorbutic diet. Figures 4 to 8 show similar curves before and after supplementing with ascorbic acid and in

some cases again after withdrawal of ascorbic acid.

Fig. 7.

B. Decolorization time in groups of guinea-pigs receiving different doses of ascorbic acid

To note the effect of the administration of different doses of ascorbic acid to guinea-pigs on scorbutic diet three batches of guinea-pigs, each numbering five, were placed on scorbutic diet.

Fig. 8.

acid was considerably less than in those receiving 1 mgm. and 0.5 mgm. of ascorbic acid. The average time of decolorization in guinea-pigs receiving 1 mg. was also less than in those receiving 0.5 mg. of ascorbic acid but the difference was not considerable (table I).

TABLE I

	Guinea-pig number	Decolorization time (mean of seven days' readings)		Mean decolorization time, of group
		mins.	secs.	
Group 1 (2 mg. ascorbic acid supplement)	1 2 3 4 5	2 1 1 1 1	14 52 30 30 30	1 min. 49 secs.
Group 2 (1 mg. ascorbic acid supplement)	1 2 3 4 5	2 2 2 2 1	22 8 10 43 55	2 mins. 15 secs.
Group 3 (0.5 mg. ascorbic acid supplement)	1 2 3 4 5	2 1 2 3 2	12 44 30 10 9	2 mins. 21 secs.

They were fed 2 mg., 1 mg., and 0.05 mg. of ascorbic acid, respectively, by mouth daily for 30 days. Their weights and decolorization time were noted on alternate days. The intradermal test time for the last seven days of the experiment was measured for each group of animals. It was noticed that the average decolorization time in guinea-pigs receiving 2 mgm. of ascorbic

[Note.—The means and standard deviations of the three groups are:—

Group 1 1' 43" ± 20"
" 2 2' 16" ± 18"
" 3 2' 21" ± 32"

The mean of group 1 is significantly different from those of groups 2 and 3, but the means of groups 2 and 3 are not significantly different from each other.—
Editor, I. M. G.]

C. Decolorization time and the urinary excretion of ascorbic acid in human subjects before and after a big dose of ascorbic acid.

Nine human subjects varying from 21 to 38 years of age were chosen for the experiments. The urinary excretion of ascorbic acid and the decolorization time in the intradermal test under normal conditions were determined. Each of them was then given a dose of 700 mg. of ascorbic acid and the decolorization time was again estimated. This was done in order to see how far the ingested ascorbic acid increased the urinary output of ascorbic acid and decreased the decolorization time. If the individuals are normally receiving adequate quantities of ascorbic acid, the urinary output of vitamin C should be sharply increased by the ingestion of 700 mg. of vitamin C.

In order to estimate the total amount of ascorbic acid excreted in 24 hours, the urine was collected over pure concentrated sulphuric acid in brown hottles. The strength of the acid in the urine was 5 per cent, which, in our experience, has proved most efficient in preserving the ascorbic acid. We have mentioned elsewhere (Guha and Sen Gupta, 1938) that the most suitable method for estimating total ascorbic acid comprising ascorbic acid, dehydro-ascorbic

given in table II and the corresponding time of decolorization in the skin test (0.01 c.cm. of the dye injected into the forearm) for the different individuals before and after ascorbic acid ingestion are also indicated.

In almost all these cases a sharp rise in the ascorbic acid excretion was observed indicating that the subjects were saturated or nearly saturated with reference to vitamin C. On the other hand, it will be observed that in all cases except no. 6 there is also a sharp fall in the decolorization time in the skin test after ascorbic acid ingestion. This might be interpreted to mean that the body was not saturated and, therefore, retained a part of the ascorbic acid ingested. On the other hand, it is possible that even if the body is saturated with its normal requirements of vitamin C, extra vitamin C may accumulate, perhaps temporarily, in the skin and other organs. The present experiments are described only to indicate the apparent discrepancy between the urine and skin tests and further detailed experiments over somewhat prolonged periods are in progress to throw more light on the relationship between the urine test and the skin test and to evolve a method for the assessment of the correct vitamin-C status of the body.

TABLE II

Subject	Age	BEFORE INGESTION OF ASCORBIC ACID			AFTER INGESTION OF ASCORBIC ACID

acid, if any, and ascorbigen (combined ascorbic acid), if any, appeared to be to heat the material in an atmosphere of hydrogen sulphide to reduce the dehydro-ascorbic acid and split up ascorbigen and then to titrate an aliquot against 2:6 dichlorophenol indophenol in the usual manner, after driving out the hydrogen sulphide by means of carbon dioxide or nitrogen. Another aliquot of the solution after removal of hydrogen sulphide was treated with ascorbic acid oxidase (prepared from cucumber) and titrated against the indophenol reagent. The difference between the titration values before and after oxidase treatment gave the 'true total' ascorbic acid. The results obtained by this method applied to the urine of the human subjects before and after the ingestion of 700 mg. of ascorbic acid are

[Note.—The means of the true total ascorbic acid before and after ingestion of ascorbic acid in these nine cases are 67.97 ± 25.37 and 125.94 ± 50.45 ; the difference is 'very significant' statistically. The means of the intradermal test times before and after ingestion are $3' 52'' \pm 2' 16''$ and $2' 53'' \pm 1' 23''$; these means are not significantly different from each other.—Editor, I. M. G.]

D. The intradermal test as applied to some Bengali young men

The intradermal test was applied to a number of Bengali young men, mainly students, of ages varying from 20 to 30 years and the results are shown in table III. According to Rotter's standard they seem to indicate that the vitamin-C status of these young men is within normal limits. The limiting factor for this test is, of

course, the degree of pigmentation of the skin. If the skin is too dark, it is obviously not possible to carry out the test.

TABLE III

[Note.—The mean of 41 estimations in normal Bengalis is 4 minutes 53 seconds \pm 1 minute 48 seconds. The normal range may be looked upon as from 8 minutes 28 seconds to 1 minute 16 seconds.—EDITOR, I. M. G.]

Summary

(1) The accuracy of the intradermal test for the assessment of the level of vitamin-C nutrition was tested with guinea-pigs under controlled conditions. It was observed that if the guinea-pigs are placed on a scorbutic diet the time of decolorization increased approximately at the same rate as the body weights diminished, the two curves, in fact, following each other fairly closely. When normal diet or ascorbic acid was given to these scorbutic guinea-pigs, the decolorization time gradually diminished and the body weight rose at fairly equal rates. If the ascorbic acid supplement was withdrawn, the weight

AN EXPERIMENT IN COOLIE LINE SANITATION: EFFECTS ON HEALTH

By K. P. HARE, M.B., B.S. (Lond.), L.M.S.S.A.
Medical Officer, Timgri Medical Association, Assam

Introduction.—In a previous communication (1938) I described the construction of a set of latrines for a coolie line and gave reasons for the adoption of a particular design. It has not yet been possible to estimate the effect of these latrines on hookworm incidence owing to the absence of a preliminary stool survey of the line in question (see previous report). I am, however, in a position to report on their effect on general health and happiness and on dysentery incidence and, also, on their construction.

(Continued from previous column)

curves and decolorization time curves again followed each other approximately.

(2) In another set of experiments in which three separate groups of guinea-pigs were fed on a scorbutic diet, supplemented by 2 mgm., 1 mgm. and 0.5 mgm. ascorbic acid, respectively, the average decolorization time (observed during the last seven days of experiment) with the group receiving 2 mg. ascorbic acid was considerably less than that observed with the group receiving 1 mg. ascorbic acid. The average time of decolorization with the group receiving 0.5 mgm. ascorbic acid was also less than in the group receiving 1 mgm. of the vitamin, but the difference was not considerable. It would seem, therefore, that when the dose of vitamin C begins to be low, the vitamin disappears from the skin relatively more slowly.

(3) The excretion of 'true total' ascorbic acid in the urine and the decolorization time in the skin test with nine healthy male human subjects before and after ingestion of 700 mg. ascorbic acid were observed. In nearly all cases there was a sharp rise in the ascorbic acid excretion. The decolorization time was also, however, sharply reduced except in one case. These results are discussed.

(4) The intradermal test has been applied to 41 Bengali young men, mainly students, and their vitamin-C status appears to fall within normal limits.

Our sincere thanks are due to the Calcutta University Students' Welfare Committee for a personal grant to one of us (S. B.) and to Dr. A. N. Chatterjee, secretary of the Committee, for his valuable help. We wish also to thank the Indian Research Fund Association for financing our researches on ascorbic acid.

Effect on health and happiness.—The improvement in the morale of the coolie living in the Balimara line has been remarkable. They have always, from the very beginning, taken advantage of their latrines and have kept them clean themselves. The line is now a model of cleanliness and tidiness and one is struck by the complete absence of odour. The assistant medical officer of the estate reports a drop in the sickness figures for Balimara as compared with the remainder of the estate and the manager reports an increased wages bill owing to reduction of absenteeism. Many of the occupants of other lines have applied to be transferred there and, when told that there was no room, have agitated for similar latrines in their own lines. The management fully intend to carry out this work early in 1939.

Hookworm incidence in the line.—As mentioned above and previously reported (*loc. cit.*) it was impossible to carry out a preliminary stool survey of this line but stools were collected from a random sample of fifty-six persons from the other lines and examined. All the inhabitants of the Balimara line were given a mass treatment with oil of chenopodium (m. xxx) in March 1938. A stool survey was also carried out on the total population, one hundred and twelve persons, of an isolated line on another estate. This is acting as a control line as it possesses no sanitary amenities. Immediately after the survey (in March 1938) all the inhabitants of that line also received a mass treatment with oil of chenopodium (m. xxx). In November 1938 a second survey of the control line and a survey of the Balimara line were carried out using the same technique as before. These surveys were immediately followed by a second mass treatment using tetrachlorethylene (one drachm for adults and proportionate doses for children). The results of the surveys are given in tables I, II, III and IV. Table IV in fact probably gives a fairly accurate picture of the position in March 1938 since Hare and Dutta (1939) have shown that the absolute-cure-rate for a single treatment with oil of chenopodium (m. xxx) is only five per cent, using the mode of administration normally employed in this district.

TABLE I

Stool survey of 112 persons, being the total population of the control line, carried out in March 1938

Ascaris	77	68.1
Trichuris	59	52.2

TABLE III

Stool survey of 56 persons, being a random sample of coolies living on Dirial Tea Estate excluding the Balimara line, carried out in April 1938

Infection	Number infected	Percentage incidence
All helminths	49	87.5
Hookworm	40	71.4
Ascaris	33	58.9
Trichuris	29	51.8

TABLE IV

Stool survey of 126 persons, being the total population of the Balimara line, carried out in November 1938

Infection	Number infected	Percentage incidence
All helminths	121	96.0
Hookworm	103	81.7
Ascaris	95	75.4
Trichuris	88	69.8

The latrines also appear to have had some effect on the incidence of 'water-sores' which are most probably the result of irritation of the skin caused by penetration of hookworm larvae. The Balimara line, as is shown in table V, had previously a high incidence of water-sores as compared with the remainder of the estate. This incidence dropped during the worst months of 1938 to a figure slightly below that for the

TABLE V

Water-sore cases in Dirial Tea Estate

Line	Period of observation	Number of cases	Percentage incidence
Balimara	July 1937	21	17.5
Other lines	August 1937	102	10.3
Balimara	September 1937	11	8.0
Other lines	Do. 1938	91	9.4

remainder of the estate. That a larger drop has not been shown is not surprising in view of the established longevity of the hookworm larva.

Effect on dysentery

It was a reasonable expectation that the provision of sanitation would have some effect on the incidence of dysentery, already improved by the provision of a pure water supply. Tube-wells were sunk in other lines of the estate in May 1936 but not in Balimara until May 1937. The effect was to reduce the dysentery incidence of that line to that of the remainder of the estate. The latrine system was installed in Balimara line during February 1938. The actual effect of the latrines, though not dramatic, has been satisfactory as is shown in table VI.

TABLE VI
Dysentery on Dirial Tea Estate

Line	Period of observation	Number of cases	Percentage incidence
Balimara	June 1936 to May 1937.	9	6.9
Other lines	Do.	38	3.7
Balimara	June 1937 to February 1938.	3	2.3
Other lines	Do.	27	2.6
Balimara	March 1938 to November 1938.	5	3.5
Other lines	Do.	43	4.4

Though dysentery assumed epidemic proportion in the remainder of the estate during the summer of 1938 and gave rise to great anxiety, it never spread to the Balimara line. Of the cases reported above three arose sporadically and the other two occurred when there was no other dysentery in the remainder of the estate and there is reason to believe that they were due to consumption of infected food from the bazar. If these cases are ignored, the incidence in the Balimara line is reduced to 2.1 per cent. It would appear therefore that the problem of dysentery in tea estates can be adequately dealt with by the provision of a pure water supply and effective sanitation.

Construction

There has been no sign of caving-in of any of the bored-holes although no lining of any description has been used and the housings have stood up to the very inclement weather of the 1938 rains excellently. The use of a 'topping' of two courses of pucca bricks and the coating of the Kapax bricks with tar and crude oil have proved absolutely effective in preventing collapse of the walls due to damage by heavy rain.

Acknowledgment.—I wish to acknowledge my indebtedness to Dr. H. C. Das, assistant medical officer, Dirial Tea Estate, for his patient work in searching through his sickness records for the material embodied in tables V and VI.

THE SOURCE OF STREPTOCOCCAL INFECTION IN PUERPERAL FEVER

By H. GHOSH, M.B., M.S.P.E. (Paris)

and

S. MUKHERJEE, M.B., D.T.M.

Department of Bacteriology, Indian Institute for Medical Research, Calcutta

PUERPERAL FEVER, so far as it has been possible to demonstrate, may be due to one or more of the following micro-organisms, viz, *Streptococcus*, *Staphylococcus*, *B. coli*, *B. welchii*. Puerperal fever due to streptococcus is the commonest. Even in well-equipped hospitals where the greatest possible aseptic precaution is taken, puerperal sepsis cannot be avoided. This induced scientific workers to search for the source of infection and streptococcus being the commonest cause of puerperal infection, investigation on the source of this micro-organism was taken up with much care and interest.

There can be two possible sources of streptococcal infection, (1) Autogenous, i.e., the patient herself can harbour a hæmolytic streptococcus in her throat which becomes virulent at the puerperium when the defensive power of the body is low, and (2) Exogenous, i.e., infection may occur from contact with medical attendants, nurses or visitors.

It was shown by Dr. Dora Colebrook that in 38.1 per cent of streptococcal puerperal infection the strains of *Streptococcus hæmolyticus*, isolated from the throats of the patients, serologically corresponded exactly to those isolated from the blood or vaginal discharge, in other words the infection was autogenous. Our investigation was directed to determining the sources of infection in this country. From obvious difficulties in collecting materials from visitors to the maternity cases we could not ascertain directly as to how far contacts were responsible for the source of infection by *Streptococcus hæmolyticus*.

Method of investigation.—Materials for investigation were collected from Baldeodas Maternity Home, Medical College Hospital and Calcutta Medical School Hospital.

As soon as a maternity case was admitted into the hospital one swab from the throat was taken and the streptococcus, if any, was isolated. Hæmolytic and non-hæmolytic strains were grouped separately. Subsequently, if any case developed puerperal fever, one or sometimes two on different occasions, vaginal swabs were taken to find out if there was any streptococcus (either hæmolytic or non-hæmolytic) present.

(Continued from previous column)

- Hare, K. P. (1938). *Indian Med. Gaz.*, Vol. LXXIII, p. 609.
Hare, K. P., and Dutta, S. C. (1939). *Ibid.*, Vol. LXXIV, p. 198.

High titre sera were prepared from 21 strains of *Streptococcus hemolyticus* isolated from the throat or other sources and 8 different serological groups were obtained. These high titre sera were used to determine the agglutinability of the strain of streptococcus isolated from throat and vaginal swabs of patients who developed puerperal fever, by both direct absorption of agglutinin method, for the precise identification of each serologically homologous group of *Streptococcus hemolyticus*.

Bacteriological technique

Preparation of high titre serum.—All the high titre sera prepared, gave agglutination with an homologous strain in 1 in 1,000 dilution or higher.

After the high titre sera were prepared these were tested serologically to find out whether they belonged to different groups. From these 21 high titre sera, we were able to obtain 8 serologically different groups, which would agglutinate most of the streptococci isolated from throat or vaginal swabs of our series.

Serological identification of the different strains of streptococcus.—A direct agglutination test was made with all the different groups of high titre sera. When agglutination was found to be strongly positive, absorption test was performed for confirmation.

Many strains showed auto-agglutination. It was found, as suggested by some workers, that by culturing at a temperature between 22°C. and 26°C. auto-agglutination could be avoided in most cases.

Result

Seven hundred and fifty maternity cases were examined, of which only 44 developed fever during the puerperium. Of these 44 cases 3 showed *Streptococcus hemolyticus* in the throat swab and 17 showed it in vaginal swabs and 1 non-hemolytic streptococcus was isolated from the vaginal swab.

The result is given in the tables below :—

Number of vaginal swabs of cases with normal puerperium	Hæmolytic streptococcus	Non-hæmolytic streptococcus
51	1*	5

* No hæmolytic streptococcus found in the throat swab of this case.

Discussion of results

Fifty vaginal swabs were examined before confinement, 4 only showed non-hæmolytic streptococcus and one only showed hæmolytic streptococcus. Except two cases which had very high temperature during the puerperium and where non-hæmolytic streptococcus was isolated from vaginal swabs, all the rest had normal puerperium. These two cases, however, yielded promptly to anti-staphylococcus serum but did not show any result with anti-streptococcus serum or prontosil treatment.

Fifty-one vaginal swabs from cases with normal puerperium were examined. Five showed non-hæmolytic streptococcus and one only showed hæmolytic streptococcus but in the throat swab of this latter case no hæmolytic streptococcus was obtained.

It will be evident from the above results that except in one out of 17 cases of puerperal fever due to *Streptococcus hemolyticus* the source of infection was not from the throat of the patient

CLINICAL NOTES ON THE TREATMENT OF ACUTE CARDIAC BERI-BERI

By MIN SEIN, M.B. (Cal.), M.R.C.P. (Lond.)

CAPTAIN, I.M.S.

General Hospital, Rangoon

BERI-BERI is prevalent in the urban areas in Burma, particularly in the seaport towns of Rangoon, Moulmein, Bassein and Akyab. The incidence of the disease falls largely upon Telegu coolies and Chittagonian labourers or artisans whose staple diet is rice. On account of poverty these people have to depend on the cheapest variety of rice and their diet is also otherwise deficient in essential constituents.

The disease is quite well known amongst the Burmese who have special names for the wet as well as the dry types. It generally affects coolies employed by big firms, who have to work for months in the jungle, e.g., forest work. The paralytic or polyneuritic type of the disease, which generally runs a chronic course in Burma, is uncommon amongst the native population as probably the patients get back to better conditions after the field work has been done and they can get a diet which satisfies the nutritional requirements.

From accounts given by coolies the acute type is not uncommon amongst the Burmese but cases are not often admitted to hospital hence opportunities for their study are not easily obtained.

In Bassein civil hospital the majority of patients come from the Telegu and Chittagonian groups and the disease is of the chronic type requiring institutional treatment for months.

(Continued from previous page)

herself. Only 38.63 per cent of cases of puerperal fever were due to *Streptococcus hæmolyticus*. Taking into consideration the experimental error, delay in delivery of collected materials, the percentage of streptococcal puerperal fever might have been, in our opinion, higher than the figure we obtained. In one case of puerperal septicaemia where no streptococcus was isolated either from vaginal or throat swabs the patient developed severe erysipelas which yielded promptly to anti-streptococcus serum. There was no mortality among the cases examined.

Conclusion

1. A large percentage of puerperal fever in this country is due to *Streptococcus hæmolyticus*.
2. Autogenous infection occurs only in a very small percentage of cases. The source of infection seems to be mainly exogenous.
3. Puerperal fever due to staphylococcus was not infrequent.
4. In hospital cases examined, the percentage of mortality from puerperal fever is low.

Therefore the appearance of stray cases of acute cardiac type is likely to be overlooked.

The dramatic nature of the onset of the acute cardiac type of beri-beri and the clinical appearance of the case are striking. The rapidity of heart failure and death in untreated cases, and even in cases which die in spite of treatment, warrants the disease being classed as a medical catastrophe.

Experience shows that the attempt to treat such cases with a set beri-beri diet consisting of red rice, bean sprouts, raw onions and other green vegetables is practically useless. Even the addition of marmite and the more recent preparations of vitamin B in therapeutic doses are of no avail.

Clinical features

In hospital cases the patients are desperately ill on admission and present the picture of acute heart failure with dilatation. In other cases the patient suddenly develops these symptoms whilst under treatment for beri-beri. There is marked orthopnoea with cyanosis and restlessness. The patient fights for breath as during an attack of asthma, but he is too ill and weak to sit up. The face is purple and appears bloated and the veins in the head and neck are frequently dilated and tortuous. There may be oedema of lower extremities or, in cases which have survived the attack for a few days, there may be some degree of general anasarca. On physical examination the following features are noticed:—The heart is dilated, the cardiac sounds are muffled and there may be a tic-tac rhythm. The pulse is rapid and may be imperceptible at the wrist. The blood pressure is consistently low. There are other signs of congestive failure such as enlarged and tender liver, oedema of feet or general anasarca, and basal congestion in the lungs. Frequently the patient complains of epigastric pain and vomiting.

Before patients die, respiration appears to become ineffective and gasping, and the heart seems to go into a state of flutter.

The post-mortem appearance consists of an extremely flabby heart and signs of acute passive congestion in the lungs, liver and other viscera.

Case 1.—A Burmese male, aged 34, was admitted to Rangoon General Hospital at 6.45 a.m., and the following history was obtained from his companion as the patient was too ill to give it himself.

During the twenty days before admission the patient suffered from feeling of tiredness, breathlessness on exertion and headache. Acute symptoms with scanty micturition, inability to walk, pain in epigastrium and calf muscles developed within the last three days.

The patient was a well built and plethoric type of individual. He was extremely ill and the face had a purple hue with prominent and tortuous veins in the temples and neck, and marked visible pulsation more prominent on the right side. The fingers and toes were also cyanosed and cold. There was extreme orthopnoea and restlessness. The heart was dilated and the sounds were muffled and weak. The pulse was soft and the rate was 72 per minute. There was congestion in the base of the lungs and the respiration was shallow and hurried, its rate was 40 per minute.

THE INCIDENCE OF PLAGUE IN MAWCHI MINES AND THE ADVANTAGE OF ADOPTING EARLY PREVENTIVE AND PROPHYLACTIC MEASURES

By E. R. JAMES, M.B.E.S. (Eng.), L.R.C.P. (Lond.)

Medical Officer, Mawchi Mines, Ltd., Mawchi

MAWCHI MINES are situated on the south side of a steep hill in the mountainous tract of the independent state of Karenni, Burma. The mines cover an area of roughly 2 square miles, and have a population of about 10,000 inhabitants, about 5,000 of whom are employed by the Mawchi Mines Company. Of the remainder,

(Continued from previous page)

association with the usual anti-beri-beri diet, consisting of marinite, red rice, bean sprouts, raw onions and other green vegetables. Eggs were added to provide the proteins in the diet. Massage and electrical stimulation of the muscles were used as adjuncts to the treatment.

After this study was well on the way I had the good fortune to read a report by Hawes (1938) on the same subject which was most illuminating. Professor Hawes believes that the effect of one dose is lasting. Case 1 in the second series illustrates that the acute symptoms can recur in spite of having received 20,000 units of Betaxin.

Summary

(1) Notes of ten cases of acute cardiac type of beri-beri are given to illustrate the clinical features of the condition.

(2) The urgency of the condition and the poorness of the prognosis when intensive treatment could not be given early were demonstrated by the cases in the first series.

(3) The dramatic relief, obtained in cases which could be treated with fairly big doses of vitamin B₁, is recorded by the cases in the second series.

(4) The average dose given was 3,000 units of Betaxin intravenously in glucose solution.

(5) Further maintenance doses are recommended to prevent a recurrence of the acute symptoms.

Havero Trading Co. supplied some of the Betaxin used. This and the reports in medical literature of its efficacy led me to use this preparation for the above cases. I expect similar preparations by other reputable firms would be equally efficacious. The above cases were under my care during the period I acted as second physician at the General Hospital, Rangoon. My thanks are due to my assistant Dr. R. K. Raman and my house physician Dr. R. Edwards for their keen interest in the above study. Credit is due to Dr. Raman for the prompt treatment of the last case.

REFERENCE

Hawes, R. B. (1938). *Trans. Roy. Soc. Trop. Med. and Hyg.*, Vol. XXXI, p. 474.

about 40 per cent are families of employees. The others are shopkeepers, cultivators and local inhabitants.

About 80 per cent of the population reside in four camps. Overcrowding and congestion of habitations are necessarily marked owing to the difficulty of obtaining adequate residential sites on the precipitous hill sides.

The four main camps are:

- (1) Mill camp, situated in the valley, 2,000 feet above sea-level.
- (2) Lokhaloe camp, situated at the western end and 3,000 feet above sea-level.
- (3) Mine camp, situated just below the crest of the main hill and 4,000 feet above sea-level.
- (4) Camp 13, situated on the eastern spur and 4,000 feet above sea-level.

Communication between Mawchi Mines and the outer world is by two main roads:

(a) The Mawchi-Toungoo road—A metalled motorable road constructed by the company, which winds by steep up-and-down gradients for over 100 miles across nine ranges of hills.

(b) The Taunggyi-Loikaw-Mawchi road—Another road similar to the above, but not so steep. About 200 miles long connecting Mawchi with Loikaw, the capital of Karenni State, and Taunggyi, the capital of the Southern Shan States.

Plague was prevalent at:

- (a) Toungoo from August 1938.
- (b) Taunggyi from May 1938 to January 1939.
- (c) Mawchi Mines from December 1938 to February 1939.

This was the first occasion of the occurrence of plague in Mawchi Mines area, so that it could be considered as 'virgin soil' and the congestion of human habitations with overcrowding in the camps and the presence of a fair-sized rat population had the stage all set in favour of a severe epidemic should plague visit Mawchi.

Anti-plague measures adopted:

1. Rats were regularly trapped and destroyed. Periodic spleen smear examinations were made of any unhealthy looking rats.

2. Towards the end of November 1938 a smear was returned positive to *Bacillus pestis*.

3. Steps were immediately taken to ensure a sufficient supply of anti-plague serum to protect the whole community.

4. A rigorous rat destructive campaign was instituted. Two cyanogas appliances were purchased. Rats were destroyed by rat poison-bait, trapping and gassing. 2,095 rats were known to have been destroyed by the medical department alone by the above means during December 1938, January 1939 and February 1939.

5. General sanitation conditions were improved and enforced with a view to discouraging

to be unsuitable. When fresh medium is inoculated with a young culture readings can be made after incubation overnight.

Interesting results were obtained by making stab inoculations in semi-solid agar containing specific agglutinating sera. With non-motile bacilli (which contain O antigen only) there is no difference in the amount or character of growth in the specific serum agar and the control tube. With motile bacilli the presence of specific serum prevents the spread of growth from the line of inoculation and the growth resembles that obtained from a non-motile bacterium. The arrest of motility in specific serum agar is not a permanent feature and sub-cultures on nutrient agar soon restore the motility of the organism.

A series of 14 species of salmonellas were inoculated into semi-solid agar containing different specific sera. The results obtained are shown in tabular form. From this table it is seen

(1) Paratyphosum A serum (a:—) inhibits the motility of paratyphosum A only.

(2) Senftenberg serum (g, s:—) inhibits its own motility and that of enteritidis (g, o, m:—) and calcutta (g, o, m:—). The enteritidis and calcutta sera inhibit the motility of enteritidis, calcutta and senftenberg. The specific flagellar antigen 'g' is present in these three strains, and antibody to this antigen alone is sufficient to arrest the motility of these organisms.

(3) Paratyphosum B serum (h: 1, 2) inhibits the motility of paratyphosum B and retards the motility of *Bact. cholerae suis* var. *kunzendorf* (—: 1, 3, 4, 5) but has no effect on the motility of other organisms containing the non-specific antigens 1 and 2 such as typhi-murium, stanley, newport and aberdeen. The partial inhibition

of kunzendorf by paratyphosum B serum suggests that there is some other common flagellar antigen in these two organisms.

(4) Typhi-murium serum (i:1, 2, 3) inhibits the motility of typhi-murium and that of aberdeen (i:1, 2, 3). There is no effect on the motility of organisms possessing the same non-specific flagellar antigens but not the same specific flagellar antigen. It appears that it is the antibody to the specific antigen which is concerned in the inhibition of motility.

(5) Stanley serum (d: 1, 2) inhibits the motility of stanley and that of typhosum (d:—) and not of the other bacilli containing non-specific flagellar antigens 1 and 2. Typhosum serum (d:—) inhibits the motility of typhosum and that of stanley. Both these contain the flagellar specific antigen d.

(6) Paratyphosum C serum (c:1, 4, 5) inhibits the motility of paratyphosum C and that of kunzendorf (—: 1, 3, 4, 5). Kunzendorf serum arrests the motility of kunzendorf and partially inhibits that of london but has no effect on the motility of paratyphosum C or any of the other bacteria. London serum (1.v:1, 4, 6) arrests the motility of london and partially inhibits the motility of kunzendorf.

From the results obtained it appears that the main factor in the arrest of motility of a bacterium in stab-culture in semi-solid agar containing serum is the presence in the serum of antibodies to the specific flagellar antigens. In organisms which are permanently in the non-specific phase such as kunzendorf, motility is arrested by its own serum. The reasons for the partial retardation of the motility of london by kunzendorf serum and *vice versa* cannot at present be stated.

The results recorded suggest a new and interesting line of approach to the antigenic analysis of 'H' antigens of motile bacilli.

A Mirror of Hospital Practice

TWO INTERESTING NERVOUS CASES*

By RASAMAY BHATTACHARYYA, L.M.P. (Assam),
D.T.M. (Cal.)

Bokpara Tea Estate, Doom Dooma, Assam

(1)

A case of acute ascending myelitis

A MALE, age 30 years, caste Munda, lorry driver, was admitted into hospital on 8th July, 1938, with complaint of inability to sit or stand; duration 1 day.

* Read at a meeting of the Assam Frontier and Budla Beta Medical Society held on the 25th February, 1939.

Family history.—Nothing of importance.

Previous illness.—Excepting occasional attacks of malaria, his health has been generally good.

Present illness.—On the evening of 8th July, after return from work he felt pain all over the body accompanied by fever. The next day he attended the outdoor dispensary and the compounder in charge gave him a dose of sodium salicylate mixture (grs. xx to an ounce). On the following day he again attended the outdoor dispensary and took a dose of purgative (two ounces of saturated solution of magnesium sulphate). On the 8th July he was unable to sit

or stand and was brought to hospital where he was admitted as an in-patient.

Condition on admission.—General appearance fairly good. Pulse rate 90 per minute, temperature 97°F. which rose to 99°F. at midday. Bilious fluid was vomited twice. Tongue coated and moist. Bowels not moved. Urine retained. Flaccid paralysis of the body from the feet to the lumbo-dorsal junction. By the evening of the same day, the paralysis had extended upwards over the thorax and upper extremities with the exception of the fingers.

General symptoms.—General weakness and bodily discomfort; mental state clear; pyrexia and pain absent.

Muscular system.—no spasm or tremor; no atrophy; complete paralysis of the lower limbs; co-ordination lost; sense of passive position, passive movement and kinæsthetic sense unaltered.

Reflexes.—

Deep—knee jerk, ankle jerk and wrist jerk lost, elbow jerk present; no ankle clonus.

Superficial—Babinski absent; skin reflexes absent over paralysed areas; conjunctival and palatal reflexes present.

Electrical examination—not done.

Special senses and cranial nerves—unaffected.

Cutaneous sensibility—sense of touch, pain, pressure, heat and cold all lost over paralysed areas.

9th July—hicough and retention of urine; partial loss of power of the fingers as well.

10th—condition same.

11th—hicough and retention of urine persisted; there was involuntary discharge of semen.

12th—brain somewhat confused.

13th—sphincter control lost, leading to involuntary evacuation of bowels; some wasting of the lower extremities.

14th—wasting of the whole body specially marked in the lower extremities with distortion of the right foot; difficulty of deglutition; bed sores developed; patient looked somewhat exhausted.

15th—condition about the same.

16th—wasting and exhaustion more marked.

17th—persistence of all the above symptoms; patient semiconscious.

18th July—death due to exhaustion.

(2)

A case of Landry's paralysis

A male, age 40 years, caste Munda, was brought to hospital on 14th July at about 10 o'clock with complaint of inability to stand. He had worked as usual the previous day but noticed this disability early in the morning when he attempted to get up from the bed. Nothing was known about his family history and except over-indulgence in alcohol, there was nothing particular in his personal history.

Condition on admission.—General appearance good and robust. Pulse rate 80 per minute, temperature 99°F. Flaccid paralysis of both the legs; knee jerks and ankle jerks lost; Babinski's reflex absent. In three hours' time paralysis extended to the thighs. Next day the abdominal muscles were found to be paralysed. On the third day paralysis spread to the thorax, upper extremities, neck and face. No wasting or sensory disturbance were noticed. No bed sores developed. Sphincters were unaffected. The patient died of respiratory failure on 20th July.

Comments

(1) In the experience of the writer, both these cases are of rare occurrence in tea garden practice in Assam.

(2) They occurred almost simultaneously in the same caste of people and had a rapid and fatal termination suggesting some ætiological connection in the nature of infection.

(3) Both the cases had close clinical resemblance but Landry's paralysis was differentiated from ascending myelitis (i) by the absence of sensory disturbance and of atrophic changes and (ii) by the retention of sphincter control.

Acknowledgment

I am grateful to my chief Dr. H. L. Slaughter for his valuable guidance and kind permission to publish these case notes.

A LACERATED SEPTIC WOUND OF THE TONGUE TREATED WITH COD-LIVER OIL

By J. C. DUTTA, L.M.P.

Assistant Medical Officer, Rajah Alli Tea Estates Ltd., Hoogrijan P. O., Assam

A LIXE CHOWKIDAR, aged about 35, was admitted into the Rajah Alli Tea Estate hospital with a lacerated wound of tongue.

The injury was the result of a fall from a cycle. The tongue was badly torn in the middle and there was severe hæmorrhage. On the following day the patient could not talk as the tongue was very badly inflamed and tender to touch.

I at once gave him liquor ferri perchloridi gargle which stopped the hæmorrhage. On the second day I found that a very bad odour was coming from the patient's mouth. I then gave him Sanitol gargle four times a day. The wound was full of sloughs and I tried Monsol also without success. I finally applied cod-liver oil to the wound and after a week I found that the sloughs were almost gone and the ulcer was clean and healthy. The separated portion of the tongue was united and there was no offensive smell. By the second week the patient had recovered completely.

I am indebted to Dr. K. P. Hare for his permission to publish this note.

A CASE OF AORTIC ANEURYSM

By MOHD. MOHSIN ALI ABBASI, M.B., B.S.

Ripon Hospital, Simla

A HINDU MALE, aged 45 years, hawker by occupation, was admitted to the Ripon Hospital, Simla, on the 8th March, 1939, complaining of a swelling over the front of the upper part of the left side of his chest; duration—2½ months.

The patient stated that some time previous to the appearance of the swelling he suffered from pain in both his arms for which he took some indigenous drugs from a *vaid* in the Hills. The pain was relieved, but the present swelling appeared and was attributed by the patient to the collection of some impure elements of his body.

He had been engaged in his occupation as hawker, which involved the carrying of fairly heavy loads on his head, up to within a few days of his admission into the hospital. No history of venereal disease was forthcoming, but the probability is that he had been infected with syphilis, a disease which is rampant in the Simla Hills.

Physical examination

Local condition.—There was a large tender, soft, fluctuant, convex, somewhat lobulated swelling measuring 5 inches vertically by 6 inches transversely which extended from the right sterno-clavicular joint to the middle of the left clavicle and from a level just below the thyroid notch on to the left side of the neck, down to the level of the 2nd left rib, covering the manubrium sterni. The swelling displayed marked expansile pulsation. There was a round, dry, brown scab about one inch in diameter on the skin over the summit of the swelling which had been produced by application of some counter-irritant.

Heart sounds in the mitral and tricuspid areas were feeble, no sounds were heard over the pulmonary and the aortic areas, nor over the swelling.

The radial and brachial pulses were not perceptible, pulsation in both the femoral arteries was feeble.

The pupils were normal, regular and reacted equally on both sides.

The patient's general health was poor. He was very anæmic and ill-nourished. The tongue was red and fissured, and the teeth were unhealthy. The liver and spleen were not enlarged. The temperature was elevated to the region of 100°F. He had a troublesome cough and crepitations were audible over the lungs. The circumferential extent of the swelling in the coronal plane is evident in the print of the x-ray film which is given below:—

On 10th March the patient sank rapidly, and retaining consciousness almost to the end, he died at 10-25 a.m. on that day.

On 12th March a necropsy was performed by the civil surgeon, Simla, which revealed a large aortic aneurysm extending from just distal to the aortic valve as far as the commencement of the descending aorta. The sternomastoid muscles were stretched over and closely adherent to the wall of the sac. The sac was full of blood clot which weighed 1 pound and 8 ounces. The greater part of the clot was soft and

red. The wall of the sac was lined by pinkish-white organized thrombus.

The inner lining membrane of the sac showed irregular diffuse atheromatous thickenings. The heart was not enlarged and its valves were healthy.

The orifices of the great vessels springing from the aortic arch could not be detected from within the sac. The manubrium sterni had been almost completely destroyed. There remained only a ragged remnant at its junction with the body of the sternum extending up obliquely to the right first chondro-sternal joint. The cartilage of the left first rib was missing, the ragged sternal extremity of the left first rib abutted on the sac wall. The right first chondro-sternal junction was intact.

The right sterno-clavicular joint was destroyed exposing the intact articular sternal end of the clavicle.

The medial half of the left clavicle was destroyed, the ragged end of the remnant abutting on the sac wall.

The lungs showed capillary bronchitis with frothy and muco-purulent secretions in the bronchioles.

The stomach, small and large intestine, spleen and bladder were normal.

The liver and kidneys were congested. The brain was congested and cedematous.

My thanks are due to Lieut.-Colonel A. Sargood Fry, I.M.S., Civil Surgeon, Simla East, for his permission to send these notes for publication.

TREATMENT OF A CARBUNCLE (NON-DIABETIC) PATIENT WITHOUT ANY SURGICAL INTERFERENCE

By J. B. DAS, M.B. (Cal.)

Kodarma, Hazaribagh District

A MALE, aged 38 years, came to me on 22nd February, 1939, with a very extensive ulcerated non-diabetic carbuncle, on his left scapular region. The whole of the back on that side was cedematous, and red, extending over the shoulder and front half of the chest. He was running a temperature of 103°F. The pulse was rapid and tongue coated. On that day magnesium sulphate compress (saturated solution) was applied, and mistura alba was given. Prontosil album, one tablet three daily by mouth, was given for the first three days. With the application of magnesium sulphate, and prontosil, the spread was checked. On the third day the temperature came down to normal with the localization of the abscess, after that I applied cod-liver oil dressing for 12 days—the dressing was changed, twice daily for the first six days and once a day for the next six days. The slough disappeared very quickly without any surgical measures. Healthy granulations formed in a very short time and the size of the ulcer gradually became very small. On the 12th day it was found that the base of the ulcer was quite healthy with a very scanty discharge. Next I applied scarlet red ointment on lint over the margin as well as over the ulcer and the dressing was removed after 48 hours and the ulcer totally healed up on the 25th day, that is on 18th March, 1939. The skin grew over the part without any scar.

Points of interest are:—

1. The immediate effect of prontosil and magnesium sulphate compress for checking the spread of the disease.
2. The effect of application of cod-liver dressing.
3. No incision required.
4. No scar formation.

Indian Medical Gazette

JUNE

INFANT MORTALITY

THERE is ample evidence during the last few years that the people of India are rapidly awakening to the importance of preventive medicine, which until comparatively recently was almost wholly the province of public health officials. The people are now beginning to form town and village health organizations in an effort to help themselves towards a better state of life in respect of better food, general living conditions and improved sanitation, all of which things will automatically bring about a reduction in disease incidence.

One of the most important branches of preventive medicine is that devoted to the care of the expectant mother, which results in the birth of a stronger infant. But to be effective this must be followed up by care of the child after its birth because even if the baby does not acquire a definite and possibly fatal disease in the first few months of its life (an all too frequent occurrence in India), if not properly nourished and protected from infections of various kinds, retardation of development both physical and mental will occur. This results in a lowered resistance to disease from which the individual never fully recovers and so a large population foredoomed to an indifferent state of health will grow up, and thus the health standards of the adult population will be lower than they should be and at the same time there will be the tendency to the propagation of a further generation of individuals who will be below par from the moment of conception.

We draw the attention of our readers to a paper elsewhere in this issue written by a worker who is engaged upon maternity and child welfare work which will well repay study by all persons interested in the improvement of the national health and physical standards. This article indicates what a long way we have to go in this country before we approach to the standards of European and American infant welfare results. Among the countries inhabited by a population chiefly of European origin, which practically always appears near the top if not actually leading in health statistics of almost any kind, is New Zealand. Probably the chief reason for the pre-eminence of New Zealand is that it is a relatively small country with a correspondingly small population and hence advanced health organizations and regulations are much easier to introduce and enforce than in a large and more thickly populated country. On this account it is clear that the task in India will be very difficult because in addition to a vast area

and an enormous population are the added factors of a low standard of education in general, and varying religious beliefs and social customs among the numerous races it contains.

One of the chief things that hinders the efficient working of public health services in India is the absence of reliable registration of births and deaths and especially the correct diagnosis of the cause of death. This deficiency is referred to in practically every public health report in India that one picks up, and in the immediate future it seems that there is not much prospect of much general improvement, although efforts are being made in certain restricted areas to acquire correct statistics of infant mortality and morbidity, as is indicated in the paper referred to above. The few reliable figures available show the infant mortality to be appallingly high compared with many other countries, but on account of the high birth rate this great wastage of child life is not obvious to the casual observer.

Although the people will be able to do a great deal for themselves if they are taught how to feed their children properly and how to prevent them acquiring diseases, the difficulty will be to find a sufficient number of teachers for the innumerable village communities throughout India. The local medical practitioner is the ideal teacher, but there is at present a state of unequal and unsatisfactory distribution of trained medical men and women, for it is an oft-repeated complaint that the cities and larger towns attract the majority of doctors so that the profession is badly overcrowded in these places, and wide areas of the country districts are without any medical help at all.

This is a problem, the solution of which is not at present obvious because there is no method of compelling private individuals, either doctors or others, to reside in any given place, so that the relieving congestion of doctors in the towns and increasing their numbers in the villages cannot be enforced. It will therefore be necessary to try and find some means whereby doctors may be induced to live in the country districts. The greatest bar to the migration of doctors from the cities to the villages is the financial one, because it is very hard for a doctor to make a living from the villagers, the majority of whom are extremely poor.

It is looking a long way ahead, but it seems possible that in time the State might be able to introduce some form of national health insurance such as is working now in many other countries, and that even minute annual contributions from the enormous rural population of India might provide sufficiently lucrative posts to induce more medical men to settle in the country districts. It is only by getting medical practitioners distributed throughout the land and all deaths correctly certified that the chief causes of death can be definitely ascertained, particularly among infants, and following this information the correct preventive measures can be instituted.

Special Article

INFANT MORTALITY IN INDIA*

By B. MUKTHA BAI, M.B., B.S., D.M.C.W.

*Assistant Professor of Maternity and Child Welfare,
All-India Institute of Hygiene and Public Health,
Calcutta*

THE infant mortality rate is the number of infants that die for every 1,000 children born alive each year. This rate is very high in India. Yet the public and the authorities concerned have not paid much attention to this very important problem. The reason, I suppose, is the high birth rate, which to a great extent obscures the issue. But as in other countries, as the economic stress and strain on the parents are becoming acute, and as they are realizing more and more their responsibility to their children, this birth rate is bound to fall. Other nations became alive to the fact when they saw the birth rate actually rapidly falling. Why should we not learn a lesson from them and begin our work earlier than they did? When they detected it, these countries could initiate a very intensive campaign against infant mortality. That required money and they could spare it. But we are not in that fortunate position. So it is better for us to prevent than cure. For adequate control of such work, proper registration of births and deaths is essential. Deaths are always better registered than births. Only in recent years is the registration of births also becoming better. For example in half Ward 8, Calcutta, the percentage of births registered was in 1934—63, in 1935—78, and in 1936—81 of the total births detected. So the infant mortality rate appears to be falling as the denominator of the factor is increasing. In truth, the total number of infants dying every year may be the same or increasing. Again the birth rate might have already begun to fall, because, in spite of improved registration, it was 38 in 1910, 35 in 1930 and 35 in 1936. Both these facts prove that we have no time to lose.

The above considerations show that unless we have stricter registration, made compulsory by legislation, we can neither rely upon the data evolved nor can we watch the progress of our welfare work. Also, we cannot compare our death rate with that of other countries.

However it may be, it cannot be denied that we have a very high infant mortality rate. No civilized country ever had the high infant death rate we have to-day. Though for British India it is said to be 162.4 per thousand live births in 1936, the Report of the Health Officer of Calcutta for 1935 records as high a figure as 338 per thousand live births in district III. In Great

Britain in 1899 when it went up to 162 per thousand live births, it created great alarm and the press and the public were said to be too saturated with the problem of reduction. But now, at this stage of civilization, when we are having more than double that number how many are aware of it? One wonders how long we can remain in this state of blissful ignorance about this most important national problem—the continuation of the nation.

It is said that high infant death rate is one of Nature's measures to check over-population and carry out her law of 'survival of the fittest'. But the fall in birth rate will become a problem before long, especially in the better portion of the race. Also, we need not try to decrease the population in this most uncivilized and unscientific way; because the Public Health Commissioner for India in his report (Russell, 1938) writes 'The resources of this country are therefore immense, but they will become available for the betterment of the people only by a well-planned campaign of economic development'. So we need not lose heart at the increase of population. We want people. We want them to be strong to raise our economic state. The other criticism that it will allow only more weaklings to live is not true, as proved by an investigation done in England by Dr. Ballard (McCleary, 1933) during the diarrhoea epidemics. In this connection he writes 'Our experience of these two epidemics, then, by no means supports an opinion commonly held that a summer diarrhoea epidemic makes its first fatal swoop upon the weakest children. Like a good many other beliefs, it will not bear the test of experience. The evidence indeed tends the other way, namely, that weakly children require a longer exposure to the epidemic cause, whatever that may be, than hearty children'. Furthermore maternity and child welfare loses its value if it allows weaklings to remain so. They can be made strong if they are properly looked after.

In considering the infant mortality and in our attempt to reduce it, we have to bear in mind that the infant life does not begin after it becomes an extra-uterine subject. As Frew (1936) says, the infant has already had '280 days of individual existence; 7 months as foetus, 7 weeks as an embryo and 7 days as an impregnated ovum, and before that still, is a prolonged but varied existence in the germinal cells of the parents'. Then it has gone through a crisis in its attempt at seeking independence from its mother. Soon after this it is suddenly brought into a new atmosphere. The infant period of an individual is different from any other period of its life. Its environments are changing, its internal organs are actively destroying things which are not needed for life and health, and building up things which will help its growth. At this period of very active growth, when it doubles its weight within six months, which it can never do in any other period of its

*Read at the meeting of the Public Health Society, Calcutta, on the 23rd December, 1938.

life, it has great capacity to recover from disease. At the same time if the disease is allowed to take the upper hand, it can do more harm and disablement than it can do in a grown-up individual. The problem of infant mortality can never be dissociated from the problem of infant morbidity. The same causes which kill some, may maim others. These maimed infants may grow up to adult age being handicapped in various ways in their discharge of duties to the state. They, therefore, grow up to be completely or partially crippled with no or diminished productive power. It is obvious enough that the state does not get what it would have got if they were healthy. This loss was really one of the causes which made the authorities in England realize the necessity for better care of infants and toddlers. It was during the last war, when they wanted to recruit young men for the army, they found that a very large number were not fit because of some disease during infancy or childhood. These diseases left their mark, made them undergrade, though they had not killed them. So we should never let any disease thrive in the infants and Nature is there to render special help in our attempt to cure them.

It is self-evident that to initiate a thorough campaign the causes of death must be ascertained. Though poverty, ignorance, prejudice and social customs play a great part in the high mortality of infants, they are not the only factors. The causes given in the reports of health officers are very unsatisfactory as the deaths are not certified by medical men. Even in some hospitals the causes of death are not scrutinized. I have analysed the records of 216 infants who died in half Ward 8 since 1933. These records are not satisfactory as we had to depend on the health visitor to diagnose the cause of death, and she in her turn had to depend on the relatives. Again, I shall be able mostly to discuss the postnatal causes as I have only a few neonatal cases. This is due to delayed registration and therefore the health visitors could not come in touch with all the infants during the early period of their lives. England achieves this object by compulsory notification of births within 36 hours of delivery. Thus the health visitors get chances to see the infants who survive the first day. Even hospitals cannot help us, as mothers usually are not kept longer than 10 days. Better light may be thrown on this aspect if I bring to your notice that in 1936, in spite of our efforts, out of the 85 infant deaths in our area only 52 were entered on cards. The births of the remaining 33 were not registered, and therefore were not on record in our centre. Most of these might have died in the neonatal period.

In this investigation the causes of death have been divided according to the two age periods—neonatal and postnatal. Neonatal is one month from the date of the birth. The other 11 months belong to the postnatal period. This

classification has been made as the number and the causes of death differ very much in these two age periods. Antenatal and intranatal deaths in the form of miscarriages and stillbirths are not discussed here. Among the 216 infant deaths that are analysed 49 = 23 per cent are neonatal deaths. The Health Officer of Calcutta (Biswas, 1935) says that 42 per cent of the infant deaths occur in the neonatal period. The Public Health Commissioner for India gives it as 60 per cent in 1936.

Causes of neonatal deaths

Prematurity.—Neonatal deaths, the majority of which are due to prematurity, are more obscure and hard to control than postnatal deaths. England, in spite of her thorough welfare work, could only bring down her neonatal deaths from 40.7 per 1,000 to 30.4 per thousand during the years 1907 to 1935. But she has in the same period succeeded in bringing the postnatal deaths from 32.4 per thousand to 9.7 per thousand. In a series of post-mortem examinations done by Dr. Bundesen and others (1938) on 911 infants, in 362 no ascertainable cause could be detected. Again, they found that out of 600 premature infants, in 320 no cause could be found, while among the 311 full-term infants, only in 42 no cause could be detected. As the causal factor cannot be detected always it is probable that infant mortality will have its 'irreducible minimum'. In this series of 49 neonatal deaths 20 were recorded as premature or unknown, while only in 8 cases among the remaining 167 postnatal deaths no cause could be ascertained. Also amongst the total of 26 prematures, in 15 cases no definite cause was found, while among the 190 full-term infants, in only 13 no cause could be determined. Among the 26 prematures in this analysis 10 died in the neonatal period. So, it shows that *prematurity* is one of the most important causes of neonatal death, and it is difficult to diagnose the cause in these premature cases. They are more susceptible to infection and injuries. The Health Officer of Calcutta (Biswas, 1935) records 1,103 as premature infants among the 2,723 of the neonatal deaths. Cruickshank by his post-mortem examinations done on 800 infants finds, that 50 per cent are due to prematurity and with some 'ascertainable cause' in the mother. Balfour (1930) in her investigation in Bombay city on prematurely born infants and those of weight below 4 lb. finds that 840 out of every 1,000 die within 3 months of birth. Balfour and Talpade (1932) say that the high infant mortality in India is to a certain extent due to high premature deaths. She attributes this to the defective diet of the mother, especially in vitamin B. She suggests that the less nutritious diet in South India may be responsible for the higher premature birth rate in that part of the country than in Punjab. She says that though the general belief is that frequent births are

causes of prematurity, she finds by an investigation done in Bombay that nearly 61 per cent are in women who are either pregnant for the first or second time. The effects on the infant because of its antenatal and intranatal conditions continue to act for some time after birth. Thus the mothers' health during pregnancy is a factor in infant mortality.

Infection.—The next important cause of death is infection. This is more important in India than in most other countries: because of the dirty habits of the *dai*. The mother escapes a fatal infection because, quite often, if the labour is normal the *dai* is called in just to cut the cord. The social customs of considering the mother and infant as something untouchable has to be blamed here along with the public authorities who do not take action against the *dai*. The *dai* cuts the cord with anything that she can lay her hand upon. The deaths due to sepsis and tetanus will continue so long we have this dirty, ignorant *dai* in our midst. In Calcutta among the 6,644 infant deaths in 1934, 440 or 7 per cent were due to tetanus neonatorum. In 1935, out of 6,061, 337 or 6 per cent were said to be due to this cause. Out of these, 220 died within one month of birth. The number that died from umbilical sepsis is not given. But it cannot be less as I found that 5 infants died of tetanus while 6 died from other umbilical infection out of the 49 neonatal deaths in our area. The Health Officer (Biswas, 1935) writes 'Tetanus neonatorum which is an entirely preventable disease is due to dirty midwifery. It is almost unknown among the thousands of cases attended by the Corporation nurses'. We know that it is entirely preventable.

Gastro-intestinal infection which is often due to ignorance of the relatives and artificial feeding is another cause of neonatal death. Out of the 49 cases 10, i.e., 20 per cent, were due to diarrhoea.

Birth injury.—This is the other main cause of death. A large number of both premature and full-term infants die from this cause. Mitra (1934) shows that among full-term infants 3.8 per cent of the abnormal and 1.4 per cent of the normal labours, die within a week. This high death rate in abnormal cases might be due to injuries. With proper antenatal care this can be prevented. Bundesen and others (1938) in Chicago found by autopsy that in 962 deaths 237 were due to this cause. In this investigation out of the 44 cases that died with complication of pregnancy 18.6 per cent were due to intracranial hæmorrhage. Of 67 cases of complication of labour 28.3 per cent were due to hæmorrhage. Of the 88 cases of operative intervention 37.1 per cent were due to the same cause. And in 23 with complications of pregnancy and labour 9.7 per cent were due to hæmorrhage. Then there are other injuries such as injury to the nerves, bones, etc. There

were 2 deaths from convulsions in the present series which might have been due to injury.

Causes of postnatal death

In the postnatal causes environment and efficiency of the mother to bring up children play an important part and the cause of these deaths can be ascertained to a great extent. In this series the causes were known in most of the cases and 85 per cent of these could have been prevented if early steps were taken.

Environment.—Basak (1938) in Bombay city found infant mortality to be closely associated with overcrowding. In London in the Ministry of Health investigation, Campbell (1929) says that infants dying from postnatal causes (gastro-enteritis and respiratory diseases) come on an average from the more crowded parts of the district. The mean rooms per person for gastro-enteritis was 0.593, for bronchitis and pneumonia was 0.625, whereas census figures for the four districts combined was 1.104 room per person. Regarding the economic condition, Woodbury (1923) finds, in 20,000 children in American cities, a relationship existing between poverty and infant mortality, as measured by the father's income. But in the Ministry of Health's report in London no such direct relationship could be obtained. There they have found that the upper classes, as for example professional and upper middle class, and the lowest class of unskilled labour have the highest mortality, whereas the intermediate, for example the skilled labour, have the lowest.

Pneumonia.—In the present series pneumonia took the greatest toll, i.e., 65 out of 216, = 30 per cent, of the total deaths. The incidence was greater, during the first 6 months it was 59 per cent. It affected the weaklings and the healthy infants equally. In certain months of the year the incidence was higher. Between April and October 80 per cent of deaths occurred. It is significant to hear from our health visitor that she almost 'Closes the death register during the winter months'. Pneumonia is less, diarrhoea is less and also the deaths due to small-pox are almost nil. Pneumonia is said to be favoured by overcrowding and low standard of living. One cannot be surprised at the number of pneumonia deaths if one sees the condition of the poor women both in *bustees* and dark, small, congested rooms of the *pucca* houses. Among my cases 201 children lived in one-room tenements with an average of 4.8 persons per room, ranging from 2 to 11 per room and 15 were living in two-room tenements. I could not find any greater increase of the incidence of pneumonia in overcrowded places than for any other disease. It may be that the rooms were too congested to make this fine differentiation, because at times 4.8 persons live in a room 5 by 6 feet. Also these mothers, in addition to the all-prevailing poverty, are very ignorant. But I will be giving a wrong idea if you think that pneumonia is prevalent only in poor houses. It is quite common in well-to-do houses, where it

is nourished by the habit of closing the doors and windows, thus making the room ill-ventilated. Often we have to criticize the mothers at the centre about the dress of their infants. There is no doubt that the mothers, especially in places with great variation of temperature during different periods of the year, need a lot of training about clothing of infants, if we want to reduce the deaths from pneumonia.

Among the total deaths that occurred from pneumonia it was found that in 25 cases mothers were ignorant and did not realize the seriousness of the predisposing causes. Rickets had been present in 6 and bronchitis had occurred in some cases once or twice before. Sixty-three of these children were normal at birth, and when it is seen that other countries can reduce the deaths due to these causes, we too should be able to do it.

In referring to pneumonia I would like to mention how often we find anæmic children with a 'weak chest'. They get bronchitis easily and we often find them with excessive mucus in the throat. These children seem to be most prone to any infection, both on account of their general condition and this excessive secretion of mucus. They react well to the administration of iron. The wheezing and œdema vanishes and the child improves in colour and vitality.

Diarrhœa.—This is the next most important cause and accounted for 26 per cent of the deaths in my series. Countries like New Zealand have shown us how entirely preventable this disease is. Out of the infant mortality rate of 32 in New Zealand, only 1.7 is due to diarrhœa. So why can't we prevent it also? This problem is becoming more and more important at the present time. Indian mothers till recently thought that breast milk is an infant's birthright and suckling is a sacred duty. That was good. But as this consciousness in mothers is decreasing because of the so-called modern ideas, the deaths due to diarrhœa will increase. In our welfare centres it is not rare to hear mothers saying that they cannot suckle their infants, there is no milk in their breasts, and so on. Often the medical profession is to blame. If a woman loses one or two children from any cause, it may be even from smallpox, the neighbours and even doctors sometimes tell her that her breast milk is not good. We all know how much effect psychological influences have on the flow of breast milk. So naturally the mother does not make an attempt to feed the child and she takes shelter under the doctor's opinion. There are still a few mothers who are very anxious to feed their babies. I hope we will be able by welfare work to save the mothers from falling a prey to the belief, that tinned milk is superior to breast milk.

Diarrhœa is often associated with artificial feeding of one sort or another. Western countries realized it many decades ago. They inquired into this cause and the first movement

in America was to establish milk depots where clean milk was given only to the needy infant, when they have made themselves certain that the mother could not feed it. They encouraged breast feeding by giving small presents to mothers. But it looks as if we are going downwards in civilization in the matter of this important subject. We all know that colostrum is the most digestible food and nature made it ready for the small delicate stomach of the infant. Cadogan (McCleary, 1933) said as early as 1748 'If we follow nature, instead of leading or driving it we cannot err . . . when a child is born there seems to be no provision at all made for it, for mother's milk seldom comes till the third day, so that according to nature, a child would be left a day and a half or two days without any food, to me a very sufficient proof that it wants none'. But in the tropical climate it will not be wrong to give some water. But what do we give? We often see cow's milk forced on the poor infant though it tries to show by vomiting, that it is not wanted. Sometimes ghee is put into its mouth, thus starting the life in a wrong way. It is often given with some dirty piece of cloth. To satisfy the relatives, even in our welfare centres we have to resort to sugar and water. It would be interesting if we could compare two sets of infants one with plain water and another with sugar and water during the first three days, as to loss of weight in the first week.

The relation of diarrhœa to artificial feeding is very significant in my series of cases. Among the 216 cases 116 were breast fed. Of these 15, = 13 per cent, developed diarrhœa. Breast and artificially fed were 73. Of these 26, = 34 per cent, developed diarrhœa. Only artificially fed were 27. Of these 16, = 60 per cent, got diarrhœa. The above figures tell their tale clearly. But this result may not be due to artificial feeding only. I believe external infection plays a great rôle too. The dirty bottles and the open milk jugs lying in an artificially fed infants' room, not to speak of the milk diluted with dirty water, and in an open can with some straw in it which is carried and supplied to the houses are certainly also responsible. Because of the poverty and ignorance about hygienic habits we should be all the more anxious to advocate breast feeding. The disadvantages of artificial feeding are many and quite a number of the infants die either from diarrhœa or starvation. This could have been prevented if the mother took the trouble to give her child what is its 'birthright'. Many mothers have neither the means nor the help and intelligence that are needed in artificially feeding a child. I am sorry to say that our medical colleges must be blamed in a number of instances. At the centres we often meet infants who are put on tinned milk, and then kept on barley water for many days, just because the child got diarrhœa when the mother was feeding it on the breast. Thus at a time when the

stomach cannot tolerate even the normal food some foreign matter is forced on it. So we can guess the result. People put the notion into the mother's head that her milk is unsuitable, though she has successfully brought up many children on a similar kind of milk. The children are often dehydrated and sometimes we have to keep them under our care for days together in our centre and teach the mother the proper kind of feeding. But often it is difficult to dislodge the belief she has on the words of her family doctor who had been treating all the diseases in her family and whom she meets often. Such practitioners should realize their responsibility and must give proper instruction. It is not rare to see infants being completely stopped breast feeding just because the mother had diarrhoea or slight fever for a day or two. I think, if she is not too ill, it will be better for her to feed and relieve her distended breast, and save her child too.

Among the 159 which died from other causes only 58 had some sort of artificial feeding. So it is seen that death due to diarrhoea is much more frequent in artificially fed children, and specially among those who are fed before the first month of life. However much is said that the breast milk yield of Indian mothers is unsatisfactory, we cannot advocate artificial feeding when we know these dangers.

Diarrhoea is most prevalent during summer—April to August. Thirty-five deaths having occurred out of the 56, = 64 per cent, and 21 only during the other 7 months. Also 41, = 77 per cent, of deaths were between the ages of 1 to 6 months, while 15 occurred during the other 6 months. It is, therefore, likely that artificial feeding during these earlier months is definitely harmful to the infant. If so many infants had died during the summer months in other countries it would have been called an epidemic and money and energy would not have been spared to investigate it. In New Zealand the proportion due to diarrhoea and other causes is about 1 to 20. When it becomes a little more they get alarmed. But here the proportion between diarrhoea and other causes is nearly 1 to 4 and it is classed as endemic. No measures are taken to find the causes and to prevent it. The only means that is within easy reach of the welfare workers is to avoid artificial feeding which we think is certainly one of the most important contributory causes of this disease, though some sort of organism is the activating cause. I could not find any relation between diarrhoea and customs and habits of people of different religions.

Starvation.—Another great defect of artificial feeding is the deaths due to starvation. In fact, out of 216 deaths, in 14 cases we could definitely find that they were due to neglect and starvation, and they were all artificially fed babies. Ignorance, poverty and poor health prevents the mother from giving enough food

and care to her children. I am sorry to say that among all deaths this cause comes third in the series. This will make me discourage artificial feeding more than any other cause. When the child is brought to us completely starved and emaciated, and we give a little milk or water and see the greed with which the infant drinks it, the sight is too pathetic for words.

Smallpox proved fatal in 11 cases. None of the children were vaccinated in time. Here, though the parents are to be blamed to a great extent, as they were visited often and advised vaccination by our health visitor, the health authorities are responsible to a certain extent too. It is to the doctors here who will be going as health officers I appeal, that one of their duties should be to remove the notion that vaccination before the sixth month is harmful. First of all they should tell this to their vaccinators who often send back our welfare centre infants if they go for vaccination before 6 months. In Lady Hardinge Hospital, Delhi, I used to vaccinate the infants before they left the maternity ward and among the few children I saw in the postnatal clinic no harm due to vaccination had occurred. So, I think, these preventable deaths would not have occurred if the infants were vaccinated.

Nine deaths were due to sepsis—boils and other infections. Three infants died of convulsions and this might be due to birth injuries or some other condition. No definite cause could be found.

There were 3 cases of tuberculosis. Lung tuberculosis is said to be rare among infants. The mothers of these infants had active tuberculosis. One infant had definite signs in the lung, the others most probably were meningeal.

Three deaths were due to anaemia. Congenital syphilis was the cause of one death and diphtheria of another.

Age incidence of important postnatal causes

Bose (1913) says that diarrhoea and enteritis show little difference between the first and second quarter, or the first three months of life considered singly. Deaths from bronchitis and pneumonia are heavier in the first month than the second and third and are the highest at the first quarter. I did not find this to be true as pneumonia was highest (i.e., 37 per cent) at the second quarter, and enteritis (60 per cent of the total) during the first four months.

Prevention.—Western countries realized the value of prevention and the public health measures increased. Though there was a fall in general death rate due to these measures, the death rate in infancy remained stationary. Side by side the birth rate was falling. This made them take more active steps against the wastage of infant lives. England had a children's hospital as early as 1739. Different countries took different measures but the first active beginning

was in the form of milk depots where good, clean milk was supplied free or at a low price, to needy infants and mothers. Also the relation between the environment, mothers' efficiency and mothers' health, and infant mortality was realized, and measures were taken to improve them. Some voluntary workers in Manchester began their health visiting as early as 1860. They knew that mothercraft like any other crafts, had to be taught. France took a leading step and called the first international congress on infant welfare in 1905 in Paris. Then Britain called the first national congress on infant mortality in 1906. Even before this people had realized that infant welfare by itself cannot be a success unless it is combined with maternal welfare. Workers had realized that nearly one-sixth of the infant deaths occur before one week and thus before they could give any help in the form of advice to the mother. Dr. Ballantyne's 'Manual of Antenatal Pathology and Hygiene' was of great help in advancing the infant welfare movement. It was realized that the infant had to be looked after even before it is born and also at the time of birth. Thus the antenatal and intranatal care started. Budin started infant welfare in the last decade of the nineteenth century and had a consultation clinic for antenatal mothers. In 1876 antenatal care was started in the form of a home for pregnant mothers who needed care before delivery. Also in 1844 the first crèche was established by Firmin for the children of married women working in factories. As early as 1882 the definite cause of infant deaths in epidemics was inquired into and there was an investigation and enquiry into epidemic diarrhoea. An infant mortality investigation was carried out by the League of Nations in 1929. Thus in various ways attempts were made to bring down the mortality of infants.

At the same time legislation was enacted which enhanced the facilities of the workers. The 'Notification of Births Act' was passed at different local areas in Britain as early as 1906. It was made compulsory over the whole country in 1915. Also the acts to protect infants in industrial and other occupations, and from cruelty were passed. The 'Midwives Act' facilitated the intranatal work. Thus matters were advanced rapidly in protecting the mothers and children by establishing antenatal clinics, giving good midwifery service, and then by the expert postnatal care to the mother and child. The child is followed up carefully and its health is looked after from the antenatal period up to school age. Then well-organized school medical inspection gave individual care to every child. After school age it is protected by insurance.

When can we hope for such a day and such a protection to each and every one of our countrymen and women? The most important thing we need at present is compulsory legislation and then only welfare work can advance. The public

is becoming conscious of the wilful waste and needless suffering of which ignorance is the chief cause. So it is not too early to bring in compulsory legislation. I heard in Lucknow that people are fined if the health authorities discover that any parent had neglected to register the birth of a child. Why does not Calcutta follow this example? In India we have to fight against many odds. Poverty and ignorance added to our unwholesome age-long customs and beliefs make many things difficult for us. But by perseverance we should win. Other countries were ignorant like us at some time in their history. In 1748 in England Cadogan writes 'The general practice is, as soon as a child is born, to cram a dab of butter and sugar down its throat, a little oil, or some such unwholesome mess. So that they set out wrong, and the child stands a fair chance of being made sick from the first hour. It is the custom of some to give a little roasted pig to an infant; which it seems, will cure it of all the mother's longings. I wish these matters were a little more enquired into for the honour of sex'. When I read this I felt quite hopeful. Some day we will be able to fight against the existing ignorance which is partially due to want of education.

Especially for India with her innumerable diseases, which cause both maternal and infant deaths, we need good antenatal care. Pregnancy anaemia which is peculiar to our country and is responsible for 23 per cent of the maternal deaths, is a cause of infant death too, so I am glad we are enquiring into its etiology and the measures for prevention. A tropical climate by itself was found not to increase the infant mortality in an investigation done in Australia, comparing the tropical and non-tropical parts of Queensland. It was 58.98 and 58.6 respectively. In Calcutta, where pregnancy anaemia is so common, and where there are so many other diseases like toxæmias which carry away many mothers, there are no antenatal beds reserved for these cases in hospitals. Welfare workers are often handicapped because of this.

Having given a chance to the mother to carry her pregnancy to full term by well-established antenatal care we can prevent many premature deaths. Then we have to see to the intranatal care. Until some legislation is passed to check the field of activity of the *dai*, it is difficult to produce marked improvement in infant mortality. The Health Officer of Calcutta (Biswas, 1935) realized that there was hardly any infant death due to tetanus among the deliveries carried by the Corporation midwives. Still was anything done to prevent the harmful work of the *dai*? I am sorry to say that the midwives supplied by the Corporation are too few in number. I was told that in an area where there are nearly 550 births in a year only one midwife is posted. How can she give time to such a large number? We cannot advise the mothers to call a Corporation midwife because they often tell us they

cannot get her at the time of need as she has too many cases to attend. We cannot send them to hospital, because the beds are too few. Only recently we had three mothers who were sent to the hospital and as no bed was available they had to hurry back home for delivery with no help and nothing prepared. It is a great problem for the welfare workers, where to send the mothers who need hospital care.

With regard to infants, when they are sick there is hardly any place to recommend them to be taken. There are only a few beds in different hospitals and rarely they are vacant. There is no convenient out-door clinic for children only, where they can get expert advice. This is another problem when we want hospital treatment for children. If it is only malnutrition due to defective feeding we keep them in our clinic in the observation beds and treat them. The rest are often left to private practitioners who, generally, have little knowledge of children's sickness and children's wants.

Lastly I would like to mention some causes which are prejudicial to good health, viz, ignorance, social customs and superstitions. Most of the mothers do not like to give up the habits they are used to. They are not sufficiently educated to be able to reason. The old mother-in-law at home or the grandmother seconds her in her wrong doing. They refuse to put in practice even regular feeding, which saves a lot of mother's time and energy and gives good habits to the infant if started from the beginning: because none in the family were reared in that way. Any cry of the child is thought to be due to hunger.

The idea that a pregnant mother should not go out much is common and harmful. A woman after delivery is made an outcast for days, varying between 10 to 40. Naturally she and her infant are kept in an unhealthy corner in the house. Only education can decrease these age-long ill practices.

Among social customs *purdah* is responsible for many deaths in mothers and infants. Osteomalacia is more common among these women. This produces deformity resulting in ill health during pregnancy, difficult labour and disablement. On account of *purdah* fresh air and sunlight are denied to the women and their young children. We have already said how a congested atmosphere predisposes to postnatal causes of infant mortality. It is said that infant deaths are less in a rural than in an urban area. The Public Health Commissioner records it as 157 for rural and 211.6 for the urban areas for every 1,000 live births, in 1936. In England they found it less in cities and villages but more in towns. In cities it may be less due to well-organized maternity and child welfare and children's hospital. We should not be surprised at the increase in number in urban areas in India. The people of the cities are mostly those

who have come from villages. There, though they observe *purdah*, generally every house has a small back yard where the women can have fresh air. Children go about and have enough fresh vegetables and other fresh things to eat. When they come to a city, in addition to the polluted atmosphere, they are shut up in small rooms with no access to sunlight or air and take very unsatisfactory food.

Early marriage is another factor. Fortunately it is becoming less common. Out of 177 primiparas on cards in our welfare centre I found 4 were the age of 13—an age when the mother herself was not more than a child; 5 were of 14 years, 16 of 15 and 37 of 16 years of age. Thus 35 per cent were within the age of 16 years. It is likely that the children of these mothers may not be strong; this fact contributes another cause for the high infant morbidity and mortality rate. Also, such a young mother cannot be expected to realize her responsibility to her child and bring it up well or train it in the proper way.

Superstitions are many. Many diseases are thought to be due to some evil spirit and no attempt is made to cure it in any scientific way. Many refuse to get their infants vaccinated in spite of knowing the benefits.

I have already spoken about the want of proper legislation

Only propaganda, education of the masses and good organization of medical and preventive help, supported by adequate legislation, can bring our infant mortality down.

Medical News

RESEARCH IN ANIMAL NUTRITION

A LANDMARK in the history of animal nutritional research work in India was reached on 11th March, when His Excellency the Viceroy opened the buildings which are to house two new sections of the Imperial Veterinary Research Institute at Izatnagar. These buildings comprise the Animal Nutrition and Poultry Research wings, as well as residential quarters for the staff. Other proposed constructions include a genetics institute.

Together with the biological products section, the new branches form a unit of noteworthy size and importance. The total cost of the new buildings is about Rs. 8,00,000.

The main functions of the institute will be the study of nutrition in relation to the health, normal growth and productive capacity of animals in India. An up-to-date building has been constructed at a cost of nearly Rs. 5 lacs and the recurring expenditure will be about Rs. 95,000 a year.

The poultry institute owes its origin to a recommendation of the Advisory Board of the Imperial Council of Agricultural Research which came to the conclusion, as a result of applications for grants from provinces, that the most effective and economical way would be the establishment of a central institute.

The work of the institute will be organized into two sections, one dealing with scientific subjects and the other with industrial processes.

On the scientific side the institute will deal with disease investigation and nutritional studies, and on the industrial side with such questions as the grading of eggs and their preservation, the preparation of table poultry and the best methods of packing and distribution of both eggs and poultry and the possibility of introducing such articles as egg powder and egg pulp to the Indian market.

The egg marketing survey showed that India has over 52,000,000 laying hens alone, that the eggs sold annually, apart from those used by villagers themselves, are worth over Rs. 5 crores annually, and that the value of hens is over Rs. 7 crores. The marketing survey further showed that there are profitable opportunities for expansion.

The institute itself has cost about Rs. 2½ lacs, and the recurring cost will be over Rs. 55,000 a year.

THE NUTRITIVE VALUE OF INDIAN FOODS

THOSE who want to plan diets either for themselves or for others will find their task made easy by the *Health Bulletin* on 'The Nutritive Value of Indian Foods and the Planning of Satisfactory Diets', a second edition of which has just appeared.

It is advisable, says the *Bulletin*, that those who are responsible for the institutional care of children, etc., and all who are concerned with practical nutrition work, should have some idea of the effects on the body of a diet which is ill-balanced and defective... e.g., of a diet which is largely composed of milled cereals and contains an insufficiency of proteins, mineral salts and vitamins—and which calls for improvement. There is a long list of diseases, common in India, due in some way or other to dietetic causes. Such are: beri-beri, certain anemias of pregnancy, keratomalacia, osteomalacia. States of malnutrition which fall short of serious disease are widespread.

Protective foods

It is not only the poor, whose choice in the matter of food is extremely limited, who are ignorant and prejudiced about diet. Many people in India and elsewhere, who could afford to consume and feed their children on an excellent diet, do not in fact do so. One can readily find among children of the more

prosperous classes cases of serious malnutrition and food deficiency diseases.

3RD ALL-INDIA OBSTETRIC AND GYNÆCOLOGICAL CONGRESS

THE 3rd All-India Obstetric and Gynaecological Congress will be held in Calcutta in December 1939. The principal subjects of discussion are: (1) anamia of pregnancy; (2) functional uterine hæmorrhage, and (3) maternity and child welfare. The Provisional Scientific Committee have formulated a scheme to facilitate investigations on those subjects. The Secretary of the Provisional Scientific Committee will be at the service of any investigator to supply any relevant information. All communications about it are to be made to Dr. S. Mitra, M.A. (Cal.), M.D. (Berlin), F.R.C.S. (Edin.), F.R.C.O.G., Secretary, Provisional Scientific Committee, 3, Chowringhee Terrace, Calcutta.

TUBERCULOSIS NEWS FOR THE MONTH OF APRIL 1939

TUBERCULOSIS ASSOCIATION OF INDIA

1. THE Inaugural General Meeting of the Tuberculosis Association of India was held at the Viceroy's House at 5-30 p.m. on the 29th March, 1939. Her Excellency the Marchioness of Linlithgow, the President of the Association, occupied the chair. The meeting was attended by the foundation members, ex-officio members and representatives of all the provinces and important Indian states. Her Excellency in delivering her inaugural address explained that the most important result of her appeal for the King-Emperor's Anti-Tuberculosis Fund was the permanent establishment of provincial and state tuberculosis associations on a permanent footing and hoped that the rules and regulations will once for all lay the bogey of interference or control from the centre and said that co-ordination and good fellowship will be the watchwords of the Central Association. Her Excellency's address was followed by a business statement by General Bradfield, the Chairman of the Central Committee. He explained in some detail the policy to be followed by the centre, which by expert advice, propaganda and research is designed to stimulate interest not only of affiliated bodies but of all authorities whether Government, municipal or private. The association will seek co-operation of all agencies promoting public welfare and will try to retain in some way the connection with the Red Cross, which has been valuable in the past. The Honorary Treasurer then explained the financial position of the association, which at present with the central share from the King-Emperor's Anti-Tuberculosis Fund and the capital and balances of the King George Thanksgiving Fund amounts to Rs. 16,97,019 giving approximate annual income of Rs. 65,100. Representatives as provided for in the rules were elected to the central committee which has now representatives of various interests in the country.

The first meeting of the central committee was held at 10 a.m. on the 30th March, 1939, at the Viceroy's House under the Chairmanship of Her Excellency the Marchioness of Linlithgow.

The committee disposed of a long business agenda, and by a unanimous vote appointed Dr. C. Frimodt-Møller as Medical Commissioner for two years. Dr. Frimodt-Møller has been connected with the Madanapalle Sanatorium for a number of years and is an expert of international fame in the field of tuberculosis. Her Excellency expressed gratification at the appointment and said that she had great admiration for Dr. Frimodt-Møller's work and that to her knowledge, his work is appreciated by everybody in this country, with whom she had occasion to talk about him.

2. The 25th Annual Conference of the National Association for the Prevention of Tuberculosis, London, will be held in the College of Technology, Belfast, on the 29th and 30th June and 1st July, 1939.

ANNOUNCEMENT OF THE FRANCIS AMORY SEPTENNIAL PRIZE OF THE AMERICAN ACADEMY OF ARTS AND SCIENCES UNDER THE WILL OF FRANCIS AMORY

In compliance with the requirements of a gift under the will of the late Francis Amory of Beverly, Massachusetts, the American Academy of Arts and Sciences announces the offer of a septennial prize for outstanding work with reference to the alleviation or cure of diseases affecting the human genital organs, to be known as the Francis Amory Septennial Prize. The gift provides a fund, the income of which may be awarded for conspicuously meritorious contributions to the field of knowledge 'during the said septennial period next preceding any award thereof, through experiment, study or otherwise . . . in the diseases of the human sexual generative organs in general'. The

prize may be awarded to any individual or individuals for work of 'extraordinary or exceptional merit' in this field.

In case there is work of a quality to warrant it, the first award will be made in 1940. The total amount of the award will exceed ten thousand dollars, and may be given in one or more awards. It rests solely within the discretion of the Academy whether an award shall be made at the end of any given seven-year period, and also whether on any occasion the prize shall be awarded to more than a single individual.

While there will be no formal nominations, and no formal essays or treatises will be required, the committee invites suggestions, which should be made to the Amory Fund Committee, care of the American Academy of Arts and Sciences, 28, Newbury Street, Boston, Massachusetts, U. S. A.

Treatment of Pain : Conferences on Therapy

(From the *Journal of the American Medical Association*, Vol. III, 17th December, 1938, p. 2293)

DR. HARRY GOLD: The symptom pain stands high, if it does not actually lead, in the list of causes of disability. It is probably the most frequent symptom requiring attention in the practice of medicine. If one were to survey a fair sample of the results generally obtained with drugs for the treatment of pain, one would discover that they are not as good as they might be. The outstanding deficiencies fall into two classes:

First, one finds a considerable proportion of failures to abolish the pain. The primary objective seems often not to be attained.

Second, in a fair proportion of cases, whether the pain is controlled or not, other effects, disagreeable and sometimes disastrous, result: nausea, vomiting, constipation, distension, urinary retention, temporary blindness, deafness, skin eruptions, profuse perspiration, stupor, methemoglobinemia, agranulocytosis, acute yellow atrophy of the liver, and narcotic addiction. This is but a partial list of one that could be very much more formidable, representing the untoward reactions that follow the use of agents employed for the relief of pain.

All of this indicates that there are no ideal pain-relieving substances; our task is to consider what we need to do in order to make the drugs or medicinal agents at our disposal as effective and as safe as possible in the control of pain.

Every case of pain presents a problem. The use of drugs to control pain involves a judgment which grows out of the careful appraisal of many facts. There is a prevailing tendency in a case with pain to dig down into our bag of analgesics, fetch up something that is supposed to kill pain, and prescribe. If we do that, the range of successful treatment becomes relatively small indeed, and alongside of the little good that we do, in that way, there stands enough harm to eclipse it. Illustrations of these remarks will appear in matters that will be discussed presently.

What are the matters one needs to consider as a basis for the use of drugs in the treatment of pain, in a manner likely to yield the greatest returns with the least risk?

1. Pain is a symptom and not a disease. In our zeal to relieve it, or in our success in relieving it, there is always the danger of overlooking the less obvious and less dramatic aspect of the case, the disease itself. Recently I encountered the case of a nurse who had suffered attacks of thoracic pain. With the approval of the house officer she took large doses of an analgesic agent and obtained relief. The last attack did not respond as effectively as the previous ones, whereupon

a careful examination was made. The results showed that she had been carrying on her nursing work with a pleural effusion and active pulmonary tuberculosis. This is the sort of thing one occasionally encounters. We must bear this fact in mind constantly, that pain is a symptom and not a disease, if the relief of pain is not from time to time to prove to be a misfortune.

2. Pain labels a disease and its location. This is another fact of some importance and is closely related to the statement previously made. You have all probably heard about cases, or perhaps you know of some from your own experience, of peritonitis directly attributable to the overzealous relief of abdominal pain before a definite diagnosis has been made.

3. The cause of pain is important to determine. We all know that it is necessary to ascertain whether the cause of a headache is a brain tumour or some insignificant functional disturbance so that the cause (the tumour) may be removed. But I have in mind something less than that. From the standpoint of relief alone without removal of cause, a clear appreciation of the cause is often very helpful. For example, of three kinds of pain in the chest, the pain of intercostal neuralgia, the pain of effort angina and the pain of coronary thrombosis, differentiation is sometimes extraordinarily difficult. The agents which relieve one may be ineffective in the other. One can group other types of pain in that way; for example, pain in the legs due to myositis, vitamin-B₁ deficiency or vascular disease. The effectiveness of the relief of the pain aside from the question of removing the cause depends here on a differential diagnosis.

4. The pathogenesis of pain is a matter of some importance; whether, for example, the pain is caused by spasm of smooth muscle or anoxemia or comes about as the result of inflammatory reactions around nerve fibres or endings.

5. The severity of the pain ought to be considered. Perhaps it is not sufficiently severe to require relief by therapeutic agents. Not infrequently when you are about to prescribe for a patient with pain the patient will ask you what the medicine is for, and you will say 'For your pain'. He may reply 'I don't like medicines. I am not much interested in the relief of the pain so long as my mind is relieved that the cause is not serious'. Before we prescribe a drug, the question should be put whether the relief will recompense the patient for other forms of discomfort which the drug may cause. You will see patients taking two or three doses of codeine a day for the relief of very mild aginal pains. The price is disagreeable stupor and troublesome constipation. Such pains can often be much better controlled if we take the trouble to assist patients in making the necessary adjustments to reduce their activities to a level within their capacity without pain.

6. The natural course of the pain is also significant: Is it going to last a few hours or several days? Is it going to recur over long periods of time? Is it the kind of pain the intensity of which is likely to fall from its peak very gradually or is it likely to subside very abruptly? Morphine poisoning often arises from the use of large doses of the drug in patients in whom severe pain subsides abruptly. In such a case the morphine may seem to be producing very little depression, and the doses are repeated to secure more relief of the pain. With little warning, however, you find the patient lapsing into a state of profound stupor with depressed respiration, and you wonder what has happened. You have used large doses of morphine in a variety of pain which tends spontaneously to come to an end rather abruptly, leaving the patient under the influence of an amount of morphine which is toxic in the absence of pain, for pain is an antidote to morphine!

The more common analgesic agents

- | | |
|--------------------------|---------------------------|
| A. Raise thresholds | 5. Salicylates |
| 1. Opium group: | 6. Magnesium sulfate |
| Morphine | 7. Sedatives |
| Codeine | B. Relax smooth muscle |
| Dilaudid | 1. Nitrites |
| Pantopon | 2. Xanthines |
| 2. Coal tar derivatives: | 3. Atropine |
| Acetanilid | 4. Papaverine |
| Acetophenetidin | 5. Calcium |
| 3. Pyrazolon compounds: | C. Special mechanisms |
| Antipyrine | 1. Trichlorethylene |
| Aminopyrine | 2. Ergotamine |
| 4. Cinchonic acid group: | 3. Caffeine |
| Cinchophen | 4. Vitamin B ₁ |
| Neocinchophen | |

7. The psychic element in pain may vary anywhere from an insignificant rôle to the sole cause of the pain. That needs to be considered also from the standpoint of the kind of analgesic agents that are to be used. Fear and anxiety increase the perception of pain, and the use of small doses of sedatives greatly enhances the effectiveness of some of the analgesic agents. When reasonable procedures in a given case seem to be without influence on the pain, one might well ask whether the patient wants his pain relieved; the pain in this case may be one of the patient's most precious possessions. That needs to be considered before one goes on increasing the doses of drugs or shifting from one preparation to another in the endeavour to relieve it.

8. Finally, drugs are only adjuvants in the treatment of pain. Physical therapy, psychotherapy and specific cause treatment in the long run play the most important rôle in any programme in which pain is the centre of interest.

These are some of the important questions demanding consideration before one writes a single word of a prescription for the treatment of pain. We must not pretend, of course, that a clear-cut answer will be always forthcoming, but I feel sure that if we ask those questions often enough we shall obtain a sufficient number of answers to make this sort of procedure extremely profitable.

Here is a list of the more common analgesic classification of them. Perhaps this is as good as any, but you may think of a better one. The first group includes those agents which raise thresholds at the centres and block the perception of pain. The second includes those which relax smooth muscle and in that way abolish the impulses at their source. The third group includes substances which exert a specific action on certain kinds of pain: trichlorethylene, ergotamine, caffeine, vitamin B₁. In some of these the mechanism is quite well established, in the case of others our knowledge is imperfect.

The more common clinical varieties of pain which present special problems are (1) headache, (2) visceral pain, (3) cardiac pain, (4) neuralgia, (5) root pains, (6) chronic arthritis, (7) dysmenorrhoea, (8) labour pain. The list is not complete. We do not have the

time this morning to go into all of these matters. Dr. Wolff is going to discuss some of the types of pain, and if any one has any special interest in others a discussion may be provoked by asking questions.

Dr. Harold G. Wolff: I am going to discuss one type of pain, and that is headache; and just one variety of headache, namely migraine. I am selecting migraine to talk about for two reasons: 1. It is said to be the commonest clinical entity that civilized man happened to fall heir to. 2. I think that the management of migraine headache allows us to discuss the clinical approach to the problem of pain in general.

By migraine headache I mean the type of headache that is usually unilateral in onset, may become generalized, is associated with nausea and vomiting, sometimes with visual and other sensory disturbances, and usually occurs in families.

There are three ways of approaching this type of headache, as there are for other types of pain: first, by considering agents or procedures that act at the site of production of pain, for instance, ergotamine tartrate, ergonovine, ephedrine, benzedrine, epinephrine, resection of posterior pituitary, ice cap, surgical ligation, resection and mechanical pressure; second, agents or procedures that act by raising the threshold of pain as, for example, codeine, morphine, acetylsalicylic acid, aminopyrine, acetanilid, phenacetin, ice cap; third, agents or procedures that act by lowering the blood pressure as in the case of glyceryl trinitrate or acetylcholine. I will disregard this third classification and limit our discussion to the first two.

Migraine results from the distension of some of the cranial arteries, chiefly the branches of the external carotid artery.

We know from our studies in the laboratory that a generalized headache can be produced with histamine, but after resection of the first division of the fifth cranial nerve such a headache will not appear in the part of the patient's head innervated by this division of the fifth nerve. Thus for clinical purposes we may consider the chief afferent pathway for headache to be the first division of the fifth nerve.

The method of investigation was as follows: The patient with a headache is put on a stretcher in a darkened room and a tambour over his temporal artery on the affected side records the amplitude of pulsations of the arterial walls. Records are made on a moving film in a camera.

In a representative patient with a migraine headache, ergotamine tartrate was given intravenously, and in the course of the next ten minutes the pulsations of the branches of the external carotid as recorded from the temporal artery had been reduced by 50 per cent and the headache had disappeared.

In another patient who received ergotamine tartrate (0.5 mg. intravenously) it happened to take about forty minutes for the headache to disappear, but again a parallel between the decline in the amplitude of pulsations of the temporal artery and intensity of the headache was demonstrated. A photograph was taken of this patient during the period of his headache, showing the large temporal vessels, both arterial and venous, standing out, which was in striking contrast to the flattened appearance of these vessels in a photograph taken immediately after the ergotamine had had its effect.

Records of pulsation of the cerebrospinal fluid, which represents the activity of the major spinal and the intracranial vessels, show variations in the height of pulsation which do not appear to be correlated with the headache or the disappearance of the headache after administration of ergotamine tartrate. Similarly, we have been able to demonstrate no correlation between the pressure of the spinal fluid and the headache. Thus I think we are at the moment justified in saying we do not know what rôle the branches of the internal carotid artery play in migraine headache, but such evidence as we have indicate it is not too important a rôle.

Photographs were taken of the retinal vessels before and after the administration of ergotamine tartrate. Although the veins appear to be a little smaller, I

doubt whether there is much change in the arteries, although there may be a slight constriction.

Further, it can be demonstrated that ergotamine tartrate does not act in terminating headache by raising the threshold to pain. For instance, in one patient who had had his headache terminated by an intravenous dose of ergotamine tartrate an injection of 0.1 mg. of histamine produced the usual acute, the short-lived, histamine headache. This then indicates that the patient is just as able to perceive the headache after the administration of ergotamine as he was before.

In one patient the intramuscular injection of solution of posterior pituitary caused the headache to disappear, but the patient was white, was tremulous, complained of bad abdominal cramps and bad precordial pain, and I feared he might faint during the experiment. It is not a drug that one would care to give regularly, and it is not one that one can count on having a constant effect. It is not to be recommended.

Ephedrine sometimes succeeds in improving or eliminating a migraine headache, via the same mechanism: a reduction in the amplitude of pulsation of the cranial arteries. But the patient to whom it is given for migraine headache becomes tense and tremulous, and the disappearance of pain is often transient since at the end of four hours the headache may return with full intensity. Therefore, ephedrine cannot be considered as either a practical or a useful means of treating migraine headache.

In our experiments ergonovine, when successful, also eliminated headache by the same mechanism as did ergotamine tartrate. It contains more of the oxytocic property of the ergot drug, will abolish headaches in only about 50 per cent of trials, and cannot be relied on to be 100 per cent effective in reducing the amplitude of pulsations of cranial arteries.

Thus, if the agent employed succeeds in reducing the amplitude of pulsation of the cranial arteries by a sufficient amount, *i.e.*, from 40 to 50 per cent, headache will be completely abolished, as is the case with ergotamine tartrate. It is thus evident that ergonovine hydracrylate cannot be regarded as an important asset in the treatment of migraine headache. Benzedrine sulfate, caffeine with sodium benzoate and pitressin are likewise unreliable in their effect on the magnitude of cranial artery pulsations and consequently in their effect on the headache. For instance, in two patients, caffeine with sodium benzoate (0.5 mg. intravenously) happened to increase the amplitude of pulsations and made the headache worse. Ergotamine tartrate subsequently reduced the pulsations by 40 per cent and eliminated the headache. Similarly, benzedrine sulfate reduced the amplitude of pulsations in another patient 25 per cent without reducing the headache, whereas ergotamine tartrate subsequently administered terminated it, and the amplitude of pulsations was seen to be reduced by 50 per cent. Ergotamine tartrate may at the moment be regarded as the most effective agent we have in reducing the amplitude of pulsations of the cranial arteries and terminating the migraine headache attack.

Before ergotamine tartrate was available, codeine was the best agent for stopping headache. One grain, or 60 mg., of codeine will stop most headaches, but how does it work? We observed a patient with migraine headache to whom 60 mg. of codeine was administered subcutaneously. As the headache disappeared the amplitude of pulsation of the cranial arteries did not change at all, an illustration that codeine does not act on the local pain-producing mechanism but raises the threshold to pain impulses arising from the stretched and dilated cranial vessels.

Codeine administered to another patient abolished his headache, again with no change in the amplitude of cranial artery pulsations. This patient soon complained that his headache had returned with about 50 per cent of its original severity. We then gave him ergotamine tartrate, the headache disappeared promptly, and the cranial artery pulsations, although they had not changed during this whole period when the headache had been transiently relieved by codeine, were now reduced in

amplitude by over 50 per cent. His migraine attack proved to be successfully terminated.

How should one manage an acute migraine attack? The patient should retire to a darkened room and remain in bed for at least two hours, and 0.5 mg. of ergotamine tartrate should be given intramuscularly as soon as it is feasible to give the drug after the onset of the headache. This drug when given intravenously will produce quicker results; that is, it takes about thirty to fifty minutes to produce effects through the intramuscular route and about ten to forty minutes by the intravenous route. Giving ergotamine tartrate by the mouth should be avoided for two reasons: 1. It eliminates the headache only about 50 to 60 per cent of the time. 2. Patients may be induced to take it too often. Patients may have the tendency to take a few pills by mouth 'every once in a while'. If it is necessary to give it by mouth for reasons best known to you at the time, give 3 mg. followed by 2 mg. an hour until the headache has disappeared or a total of 11 mg. has been given. However, I am not enthusiastic about this procedure.

Suppose the patient feels as though he is about to have a migraine attack, is there anything you can do to stop it from developing? Usually not, but you might try. The patient can be urged to go to bed and 3 mg. of ergotamine tartrate may be placed under the tongue. This will be absorbed in a few minutes and sometimes will stop the headache when repeated in 2 mg. doses hourly until 11 mg. has been given. If it does not, you are in a dilemma because you have already given ergotamine tartrate and you do not know how much more to give by the more successful intramuscular or intravenous route. I am not in favour of ergotamine tartrate by mouth. Some report the successful use of a mixture of acetanilid and sodium amylal, although I never used it and I do not know how effective it is. In any event the patient should stay in bed for two hours after such medication. Many times patients feel they are going to get a headache and don't, so you never know whether this kind of procedure is efficient or not, but you can try it and see what happens.

Don't give ergotamine tartrate more often than once a week to patients with cardiovascular disease, with or without hypertension, including those with Raynaud's syndrome, venous thrombosis, syphilitic arteritis and coronary disease; to patients with sepsis or fever; to patients with hepatic or renal disease; to pregnant women. Fortunately, most pregnant women stop having migraine attacks during their pregnancy, and the occasional woman can take ergotamine late in the pregnancy without danger; but never give ergonovine hydracrylate under any circumstances to a pregnant woman. Lastly, do not give ergotamine tartrate to badly nourished or cachectic persons. It is said that persons deficient in vitamin C do badly with ergotamine, and a poorly nourished person probably has such a vitamin deficiency. Finally, remember that in treating migraine headache you are treating the acute episode of pain and not the syndrome of migraine.

Student: What is the length of time that a patient with migraine gets relief from one injection of ergotamine?

Dr. Wolff: It terminates the attack. Attacks usually last from a few hours to a few days. The administration of ergotamine does not shorten the interval between attacks. The management of the frequency of these various attacks must be through other means than ergotamine. Ergotamine simply terminates any given attack.

Student: I should like to know the mode of action and effectiveness of trichlorethylene.

Dr. Wolff: Trichlorethylene is useful in pains of the face of any kind. It is not known what the exact site of action is, but it seems to raise the threshold for all types of pain about the head. Its chief usefulness is in trigeminal neuralgia. I think that was discovered, as you probably know, during the war when it was used as a solvent for certain airplane coverings, and the workers in the airplane factories were being poisoned, so that they became anæsthetic about the face.

Student: Has it any effect on pains elsewhere?

Dr. Wolff: I do not believe so but I am not certain.

Dr. Cattell: In the past we have been fortunate in having the collaboration of representatives from various clinical departments in connection with our conferences. The list that was put on the board by Dr. Gold includes a number of conditions which might be discussed further. I wonder if there is any one here from the Department of Obstetrics and Gynecology who might be willing to say something about the topics dysmenorrhea and labour pain. The question of arthritis is another important topic.

Dr. Andrew A. Marchetti: I will talk about the first one. Dysmenorrhea is the pain in menstruation. As you know, dysmenorrhea is either congenital, functional or acquired. I think that of course the most important thing to do is to find out what can cause dysmenorrhea. Most of the time our therapy is pointed toward patients with dysmenorrhea who have either hypoplastic, that is, more or less infantile, generative organs or a malposition, acute anteversion and acute retroflexion. In those instances we give them so-called compound powders of atropine and codeine. Each powder contains 16 mg. of codeine sulfate and 0.25 mg. of atropine sulfate, as well as 160 mg. of acetylsalicylic acid and acetophenetidin. Patients are usually instructed to take the powders every four hours when they expect the pain, and usually two or three will relieve pains which are associated with the menstrual period. In instances we have used codeine, but as a rule that does not do as well as the compound powders of atropine. As Dr. Gold pointed out, the atropine is supposed to bring about relaxation of smooth muscle. It does help, especially in case of acute anteversion. It is not 100 per cent effective, of course, and it is less effective in the patient with a hypoplastic uterus.

Some of the nitrites have been used for dysmenorrhea, but I do not believe they are used as commonly as atropine and codeine.

In the acquired dysmenorrhea it may be a uterine or ovarian tumour, an inflammatory disease or a flare-up of salpingitis which causes the pain. Peritoneal or abdominal tumours that press on the uterus itself cause pain which is not elicited until the patient is about to have a period. A uterine or ovarian tumour may cause pain in the intermenstrual period.

Then too the cachectic or the undernourished person may complain of dysmenorrhea. You will find them anæmic, and when they are built up by good food, fresh air, and the things we commonly have at our disposal for nutritional disturbances, usually the pain at menstrual time disappears.

Are there any questions that you wish to ask?

Dr. Gold: I wonder how deep is the conviction with regard to atropine for easing menstrual pain. A quarter of a milligram is a mighty small dose, and I am not sure that with such a dose it will be ever possible to demonstrate any physiologic effect.

There is a question I should like to ask as to codeine.

Are you ever worried about the possibility of drug addiction since these patients take it repeatedly over long periods of time?

Dr. Marchetti: I have never seen that. I know Dr. Kelly in Baltimore is very apprehensive about drug addiction. I asked him about it and he said he had never seen it except on one or two occasions when patients became addicted to codeine. The drug is only a temporary measure. Usually, if the dysmenorrhea is severe enough, whether it is acquired, functional or congenital, the patient comes back. In the malpositions, let us say, we insert a pessary and give the patient a therapeutic test. If the retro position is relieved by putting the uterus in its normal position or approaching that, we then know the cause of the dysmenorrhea and eventually the patient will get a suspension.

Dr. Gold: I understand that aminopyrine is widely used in dysmenorrhea. Would you care to comment on this?

Dr. Marchetti: We discourage its use, particularly because of the danger of agranulocytosis. It does

relieve the pain but not as effectively as the compound powder of atropine and codeine.

Dr. Cattell: We have a small amount of time remaining for discussion, and there may be questions relating to some of the specific conditions mentioned. It seems to me this is an unusual opportunity to ask questions of men who have given special thought to the particular problems under discussion, and we should like to have all the students participate.

Student: I have heard of the use of benzyl benzoate in dysmenorrhea, and I was wondering whether there was anything to it.

Dr. Marchetti: It helps in some instances. I do not think it is as effective as the codeine and atropine.

Student: I should like to ask Dr. Gold how large a dose of morphine may be given to control pain in coronary thrombosis.

Dr. Gold: You cannot give more than a quarter of a grain of morphine ever entirely safely. One gives as high as three-quarters of a grain or even a grain, but if so one may expect to get into serious difficulties at times because coronary thrombosis is a classic illustration of very severe pain which tends to descend from its peak rather abruptly. If you give a quarter of a grain and the pain is not relieved, then within a half to three-quarters of an hour you give another quarter and another quarter; perhaps by the third or fourth dose the pain may subside rather abruptly and at the same time you have a patient in fairly deep narcosis, in whom the pain had previously served as the antidote to the toxic effects of the morphine.

Dr. Cattell: I should like to ask Dr. Angevine whether there are some points in the management of arthritis that it might be profitable to discuss.

Dr. D. Murray Angevine: I think practically every drug has been used in the treatment of arthritis. I will mention just two types, rheumatoid arthritis and osteo-arthritis. The latter is apparently not related to infection. The ideal treatment for arthritis, just as for rheumatic fever, is rest. Sometimes it is impossible to provide rest, so we must do the best we can. We find that salicylates are of value in arthritis, but I think that is a rather general statement. We all use them because we know of nothing better, but practically 60 per cent of the patients that I see in the clinic will say 'I took aspirin, but it did not help me'. Rheumatic fever, of course, is an entirely different proposition. Our big agent for the treatment of arthritis, aside from rest, is physical therapy, and there are numerous methods by which it can be applied.

There are two points that may be of interest. It has been observed that patients with rheumatoid arthritis who become free from pain. This has been about one-half of the people who are jaundiced artificially are free from pain. It is obvious that such a method cannot be generally applied. However, such an observation is of value in that it may give us an indication as to the mechanism of pain in arthritis. In view of Dr. Wolff's statement that pregnancy relieves migraine it is of some interest that in a series of thirty pregnancies in patients with rheumatoid arthritis practically all were relieved of pain during their pregnancy. In fact, one woman said that she had gone through four pregnancies, and during them she was entirely relieved of her arthritis.

Dr. Arthur P. Richardson: Pain is, of course, without a doubt the principal reason for patients coming to doctors. It is the thing that patients usually want to be relieved of. They are not particularly interested in what the mechanism is, all they want is relief from their pain. I am not at all sure of the quotation of Pasteur, but I believe it runs like this: 'We would cure few, relieve many, and comfort all.' That is beyond doubt the outstanding duty of all doctors, at least from the point of view of the patient.

Dr. Joseph C. Hinsey: I have been concerned with mechanisms involved in pain rather than with drug effects on pain. However, I have been very much interested in this discussion. There are two or three points that occur to me. First, in the use of drugs which raise the threshold to pain, we are dealing with effects on peripheral or central mechanisms, and

probably both. It should be emphasized that the peripheral pathways traverse the dorsal roots of spinal nerves and the sensory roots of cranial ones. There are no afferent pathways aside from these.

In dealing with drugs which attack the efferent nervous mechanisms or smooth muscle directly, the phenomenon of relaxation of smooth muscles is a very important factor in the relief of pain. In Dr. Wolff's description of the relief of migraine by ergotamine tartrate and other drugs, the pulsations in the branches of the external carotid artery were reduced. I do not know what changes in the state of the smooth muscles of the arterial walls accompanied this reduction. However, in conditions in which pain is produced by anæmia and the resultant anoxia in tissues, relaxation of smooth muscle in the vascular bed induced by the action of drugs leads to an improvement of blood supply and helps to relieve pain. In physical therapy, counter-irritation may relieve pain by the induction of reflexes that relax smooth muscle both at the periphery and in the viscera, producing among other things an improvement of blood supply.

Second, there is one other place where drugs are used in the problem of pain that is of interest at the present time; that is, in the field of diagnosis. The use of local anæsthetics in the blocking of peripheral and visceral nerves gives information as to the possible relief to be obtained in painful syndromes by surgical procedures. Recently, Livingston has reported ten cases of atypical pain in the extremities produced by trivial injuries. He found that he could relieve pain by the use of local anæsthesia at the periphery in the 'trigger' zones and also by blocking the sympathetic trunks. It seems to me that the use of local anæsthetics such as procaine hydrochloride has an important rôle in the attack on a number of types of atypical pain.

Digestive Disturbances in Bottle-fed Babies

By N. LLOYD PRICE, M.D., M.R.C.P.

(From the *Medical Press and Circular*, Vol. CXC VII, 7th December, 1938, p. 520)

IN infancy a great variety of abnormal conditions, whether of intrinsic or extrinsic origin, are liable to precipitate a disturbance in the delicately balanced digestive mechanism. Broadly speaking, cases are classifiable into two groups, (1) those due to defects in the child and (2) those due to defects in the diet.

FEEDING DISORDERS ARISING FROM DEFECTS IN THE CHILD

No attempt is made in this paper to discuss disorders resulting from congenital defects in the gastro-intestinal tract, or abnormalities in its muscular innervation. This excludes from consideration such highly important conditions as congenital pyloric stenosis, pylorospasm, etc. The group of cases now being considered are divisible into three classes:

- (a) Parenteral infection.
- (b) Gastro-enteral infection.
- (c) Nervous or psychogenic.

(a) Parenteral infection

In a surprisingly high proportion of artificially fed infants with acute or chronic indigestion, or who are merely classifiable as 'marasmic', the major presenting symptoms are actually the reflection of some more deeply seated or 'parenteral' pathological process which can easily escape detection. Such parenteral infections include otitis media, pyelitis, pneumonia, empyema, etc., and no dietetic regime can hope to be successful until such foci of toxic dissemination receive appropriate treatment. The acceptance of this premise saddles the attending practitioner with the responsibility for making careful aural and urinary examinations in all cases of unexplained or unresponsive 'D. and V.' or wasting, as well as frequent clinical and, if need be, radiographic, examinations of the chest. A note of warning may be sounded here with regard to the interpretation of late urinary findings in any severe case of vomiting and diarrhoea, as such urine is almost invariably loaded with casts and contains albumin and perhaps blood.

Ætiological significance should only be attached to urinary pathology at an early stage of the disease and before the onset of dehydration.

(b) Gastro-enteral infection

There is still a surprisingly widespread belief that diarrhoea and vomiting in infancy is synonymous with gastro-enteritis and is due to some form of infection. Actually, the weight of evidence appears to prove that infective gastro-enteritis due to any recognizable pathogenic organism is rare. Inability to culture such organisms support this view, as does attendance at post-mortem examinations on fatal cases which almost invariably reveal a striking absence of demonstrable gastro-enteral pathology. In point of fact, we have no right to presume in the majority of cases anything more than gastro-enteral irritation by certain abnormal products of digestion and bacterial decomposition. That dietetic unwisdom on the one hand, or a disturbance of digestive function on the other, may be alone accountable for this is amply borne out by the history, course of response to treatment of the bulk of cases. The possibility of true infective gastro-enteritis must not, however, be lost sight of, and in so far as the clinical picture of the developed condition is closely similar, whatever the cause, precautions against case-to-case infection should be instituted wherever necessary.

(c) Nervous or psychogenic

Nervous indigestion is by no means uncommon among infants and may cause serious difficulty. The nervous baby is usually the offspring of nervous parents, and its symptoms develop within, and are aggravated by, the atmosphere of nervous tension with which it is encircled. It is for this reason that in all cases, treatment of the parents is at least as important as treatment of the baby. The following are some common feeding disorders attributable in whole or in part to the nervous diathesis:—

Acrophagy.—As a result of the restless, excited manner in which the infant attempts to bolt its feeds, there is inco-ordinate suction and excessive air swallowing. This is liable to result in vomiting from the too forcible subsequent expulsion of the swallowed air. Constipation is usual, but in some cases downward passage of air into the over-sensitive intestine causes increased peristalsis, colic and diarrhoea.

Treatment consists in quietening the baby by giving 1 grain of chloral or 2 grains of bromide 20 minutes before feeds. The use of thickened feeds may also be helpful, as will wrapping up the child in a blanket to control the constant twisting of limbs and body as it is being fed.

Habitual vomiting.—This may have owed its origin in the first instance to some minor dyspeptic upset, and been maintained thereafter by the deep imprint of a reflex pathway on an abnormally sensitive and suggestible nervous system. Some cases may be allied to pylorospasm, and it is perhaps for this reason that they sometimes respond to belladonna. A combination of 2 minims of tincture of belladonna and 1 or 2 grains of bromide may be given shortly before feeds. Thickened feeds, which are less easily vomited than ordinary feeds, may again be proved of value. Bengel's food is sometimes employed for this reason.

Rumination.—This is a rare but interesting condition, seen most commonly in girl babies. By throwing back its head and opening its mouth, the infant contrives to bring back some of the feed into the mouth, where it is re-tasted. Danger lies in the fact that a little is lost each time. Treatment consists in constantly distracting the child's attention in an attempt to break the habit. Feeds thickened with cornflour may be tried.

FEEDING DISORDERS DUE TO FAULTS IN THE DIET

This subject can best be considered under three headings:

- (a) Underfeeding.
- (b) Overfeeding.
- (c) Unbalanced feeding.

(a) *Underfeeding*

Underfeeding remains one of the commonest causes of failure to thrive, and there are certain special reasons which make it so apart altogether from any question of ignorance or neglect. Thus it is not always recognized that certain babies, particularly the thin, active and rather fretful type, require more than the normal calorie allowance to maintain progress. As much as 60 calories per pound of body weight, instead of the usual 40 or 45, may be necessary to feed the greedy fires of metabolism in this type of infant, and unless this abnormal requirement is met underfeeding is inevitable. Furthermore, it must be admitted that the condition is not infrequently overlooked altogether owing to the supervention of vomiting, colic and sometimes a form of pseudo-diarrhoea (incontinence diarrhoea), which obscures the orthodox clinical picture. These confusing symptoms are partly the result of repeated air swallowing due to the too eager gulping of a hungry baby at an unsatisfying meal, and partly to the irritable condition of the gastro-intestinal tract and, in fact, of the whole of the nervous system, which is a usual feature of the condition. It is for this reason that it is often advantageous to give for a day or two small doses of bromide or chloral shortly before feeds in these cases, and to increase feeds rather cautiously so as to avoid the risk of perpetuating what may easily turn into a vomiting habit.

There is another type of marasmic infant which should perhaps be regarded as a special problem in underfeeding. This is the baby who appears to require more food than its stomach will hold, and who makes no progress on feeding mixtures of ordinary calorie value. The various theories which have been advanced to explain this condition need not concern us. When all have been given due weight, it still appears that we do not know. What is quite certain is that many such cases of infantile atrophy will only thrive on highly concentrated feeds, such as the following butter-flour mixture (McLean and Fales' modification).

Three level tablespoonfuls of melted butter are heated in a shallow pan over a slow flame until foaming occurs, and no further odour is given off (4 to 5 minutes). Add 5 level tablespoonfuls of wheat flour and again cook gently with constant stirring until the mixture begins to brown (4 to 5 minutes). Two level tablespoonfuls of cane sugar and 1 pint of water are now added, and the whole cooked for 20 minutes. When cooked, make up to 1 quart with previously boiled milk.

This mixture is readily taken by most infants. Extra water should be given at night or between feeds.

(b) *Overfeeding*

Mild degrees of overfeeding are normally corrected by simple possetting, and effortless process of regurgitation whereby the baby rejects what it does not require. It must be sharply distinguished from the vomiting of dyspepsia set up by any severe degree of overfeeding. Such dyspeptic vomiting, which is usually accompanied by colic and diarrhoea, with the passage of copious undigested stools, must receive prompt treatment or the condition may rapidly deteriorate into one of great gravity, and is then indistinguishable from the later stages of any other acute dyspeptic upset.

In passing, it should be noted that just as there is a high calorie baby requiring more than the normal food allowance, so at the other end of the scale there is a low calorie baby, usually of a rather fat, placid type, who may show signs of overfeeding with a normal, or even less than normal, calorie quota.

(c) *Unbalanced feeding*

There is no doubt that lack of proper balance between protein fat and sugar underlies many of the most obstinate cases of digestive disturbances in the artificially fed. An unsuitable mixture leads sooner or later to the development of dyspepsia, with loss of tolerance for the particular element which has been present in excess, or even for milk in any form, and once lost, normal tolerance is very difficult to regain.

This question of tolerance is closely bound up with particular idiosyncrasies on the part of the baby, as well as with its general health, since a type of feed which a healthy baby can quite easily deal with may prove almost lethal when tolerance is lowered by an acute infection.

Disorders resulting from faultily balanced feeding can best be considered from the point of view of the main presenting symptoms or groups of symptoms, *viz*, wasting, constipation, diarrhoea, vomiting.

(i) *Wasting with constipation*

This combination of symptoms is seen in a form of infantile atrophy due essentially to a diet containing excess protein and fat and too little sugar. It usually occurs in infants fed on unmodified or insufficiently modified cow's milk, and is for this reason sometimes referred to as cow's milk atrophy. The babies look toxic and are pale, wasted and pot-bellied. There is well-marked constipation with the passage of stools pale yellow or dirty white in colour, alkaline in reaction, and somewhat offensive. If fat is sufficiently excessive, the stools may contain much white cheesy, curdlike material—so-called soap stools.

The treatment required is a diet low in protein and fat and rich in carbohydrate. Because of its low fermentability, the ideal form of carbohydrate is one of the marketed preparations of dextrin and maltose. Mead's dextrin-maltose, Glaxo malto-dextrin or Mellin's food are excellent for this purpose, and can be added in amounts up to twice the usual quantity recommended, to partially or, if need be, wholly skimmed milk diluted with half its volume of water. For older babies, Savory and Moore's, Neave's or Ridge's foods, which contain a higher proportion of unconverted starch, can be used. Severe cases do well on some form of malt soup, which can be made up with a dried preparation such as Maltosan. The best treatment of all is breast milk.

(ii) *Wasting with diarrhoea*

Babies with persistent or recurrent diarrhoea of dietetic origin are usually found to be receiving too much sugar. In many cases there is a low fat tolerance also. The undigested sugar and fat undergo bacterial fermentation in the lower bowel, with the formation of acid and gas, and giving rise to the frequent green, irritating and rather frothy stools which are a characteristic feature. There is colic, fretfulness and loss of weight, and the highly acid motions cause raw and excoriated buttocks and thighs. The advent of any marked degree of vomiting carries the case into the more serious category of an acute dyspepsia, which would be more appropriately considered in the next section.

The aim of treatment is to supply a diet low in sugar and moderately low in fat, but with a relatively high proportion of protein. Partial replacement of sugar by dextrin or dextrin-maltose will avoid the necessity for too drastic a reduction in total carbohydrate. Most cases do well if combined with this manoeuvre powdered casein or calcium caseinate is added. The latter can be given as Casein in amounts of one drachm or more per feed. A temporary reduction in fat content is always a wise additional precaution.

It will be seen that partially skimmed cow's milk fulfils the low sugar, low fat, high protein requirement quite well and, in actual fact, skimmed milk has often been employed successfully for these cases. Even more valuable is lactic acid skimmed milk, or even lactic acid whole milk. Lactic acid milk, which has become widely used in recent years for a variety of conditions, is prepared as follows:—

One pint of milk, skimmed as required, is boiled and allowed to cool. When nearly cold, up to 45 drops of lactic acid (B. P.) is added, with constant stirring. A suitable form of sugar is added and the mixture given at not more than blood heat.

Dried forms of lactic acid milk are now sold, such as Lacidac.

(iii) *Vomiting with diarrhoea*

This is the usual manifestation of the acute forms of dyspepsia of dietetic origin. The immediate cause is generally considered to be a combined excess of fat and sugar in the diet, but there is actually no sharp line of distinction between this group and the foregoing. As a matter of fact, fat exerts a peculiarly aggravating effect on all forms of infantile dyspepsia, so that, whatever the nature of the initial disturbance, a more or less severe degree of fat intolerance is likely to supervene at any time, and will thereafter gravely prejudice the whole course of the illness.

The special danger inherent in the combination of vomiting and diarrhoea is the rapidity with which serious loss of fluid and salts occurs. This, together with the associated metabolic disturbance, is revealed clinically as dehydration, intoxication and acidosis. And it cannot be too strongly emphasized that with the onset of dehydration the case enters upon a new and deadly phase, warranting the same anxious attention that would be meted out to an abdominal emergency.

The sunken fontanelle, the scooped-out orbits, the loss of skin elasticity and turgidity, together with the ashen pallor and ominous apathy, are characteristics which render well-established dehydration immediately recognizable. Detection of earlier signs of dehydration requires a more experienced eye, but its presence or imminence should be inferred whenever there is rapid loss of weight, and scanty output of urine in a baby exhibiting vomiting and diarrhoea. Clinical evidence of acidosis is provided by deep, rapid or hissing respirations, and confirmed by urinary examination, if such be possible. Cyanosis is an even more grave complication in these cases.

Diarrhoea and vomiting may be the final expression of any of the three ætiological groups—parenteral infection, gastro-enteral infection and dietetic error, and the following remarks are to be regarded as applicable to all cases in which this complication arises:—

THE TREATMENT OF DIARRHOEA AND VOMITING

Space will permit only a brief indication of the general lines of treatment. In addition to this, it must be understood that in some cases special measures will be necessary for dealing with parenteral foci of infection.

In all cases, the first necessity is to stop all food by mouth for a period of 12 to 24 hours. Half to one drachm of castor oil is of value if the case is seen early, but the risk of causing or increasing dehydration must always be considered. During the initial period of starvation small amounts of half-strength saline with glucose may be given at hourly intervals to allay thirst and maintain fluid reserve. Washing out the stomach with normal saline will sometimes stop vomiting completely. Following this initial period of starvation, treatment depends entirely upon the condition of the patient, and more particularly upon the presence of dehydration.

In mild cases in which vomiting has ceased and diarrhoea lessened, it should be possible to embark cautiously on small non-irritant feeds, such as breast milk, peptonized milk, or Secway, proceeding later to a low fat infant food, such as Allenbury No. 1, half-cream Cow & Gate, or Nestle's. Fluid requirement is at least 2½ ounce per pound of body weight in 24 hours, and it is vital to ensure that this is met by giving extra water or saline by mouth or by the rectum.

In more severe and persistent cases with clinical evidence of dehydration, drastic measures for the restoration of fluid and salt lost are immediately imperative. Every available route for the transport of fluid to the tissues may have to be commandeered. The alimentary pathway is useless, but there are three recognized parenteral routes: subcutaneous, intraperitoneal and intravenous. Of these, the last two are the only methods of real value in severe cases, and although as much as 400 to 600 c.c.s. of saline can be given intraperitoneally, in divided amounts, during 24 hours, continuous intravenous drip transfusion is the

method of choice. By this means 5 per cent glucose in normal saline may be introduced at the rate of 20 to 30 c.c.s. per hour, and the effect is often dramatic. Transfusion can be maintained if necessary for several days, during which time only tiny amounts of fluid are given by mouth. After a variable time, dependent upon the condition of the infant, and before stopping the drip, oral feeding may be recommended.

Following an acute dyspepsia of the type we have been describing, the alimentary mucosa should be regarded as being acutely hypersensitive to anything other than very small amounts of milk. For this reason the return to normal dietary must be a gradual building-up process, rather akin to desensitization. It has been well said that the quantity of the feed is more important than the quality, and it is advisable to commence with feeds as small as 1 or 2 drachms every 2 hours, alternating with equal amounts of plain water. Milk feeds can be gradually increased a drachm at a time, reverting to very small amounts on the slightest sign of intolerance. Similar types of feeds to those mentioned in the treatment of mild cases may be employed, although it is worth noting that, with careful attention to quantity, lactic acid whole milk has been used with equal success.

Sciatica and Its Treatment

By WILFRED HARRIS, M.D., F.R.C.P.

(From the *British Medical Journal*, Vol. II, 17th December, 1938, p. 1245)

SCIATICA, or pain which is referred along the course of the sciatic nerve, may arise from a great number of causes. One of the commonest is a perineuritis of the sciatic sheath in the region of the sciatic notch where the nerve escapes from the pelvis into the buttock, which may be due to the spread of rheumatic or gouty fibrositis of the lumbo-sacral fascia or lumbar muscles, known as lumbago.

The nerve trunk may be the subject of a neuritis from toxic causes, such as diabetes, lead, arsenic, etc., or an infective neuritis from dental sepsis. I have known it produced by a direct chill to the buttock from sitting on a cold wet seat; and trauma to the buttock from a fall in the hunting field or prolonged pressure from lying on a hard surface, as in coma due to mine explosions, will produce it.

TYPES OF SCIATICA

One may speak of two types of sciatica, high sciatica and low sciatica, the latter form being due to lesions in the neighbourhood of the sciatic notch, as already referred to. In this type the Achilles jerk is often lost, and there may be a tendency to lean over towards the affected side. High sciatica would be due to lesions in the neighbourhood of the intervertebral foramina around the fourth and fifth lumbar nerves, due to rheumatic or septic inflammation, or even to osteoarthritis. In this form the Achilles jerk is usually unaffected, as this reflex is concerned in the first sacral root, and there is often well-marked contralateral scoliosis in which the hip on the affected side is thrown outwards and the patient leans away from that side. In these cases forcing the body into an erect position causes pain down the affected leg. In this type of case, unless contractures have developed after many months of suffering, the scoliosis disappears on lying flat, especially if the legs are pulled down, with the body held to resist the pull. This disappearance of the scoliosis without producing pain is probably due to the nerve roots no longer being pressed on at the intervertebral foramina, and is a demonstration that the contralateral scoliosis apparent on standing is an involuntary posture assumed by the patient to relieve the pressure at these points and is not caused by arthritis of the intervertebral articulations, as asserted by Putti.

ÆTIOLOGY

Pain in the sciatic distribution may be caused by many forms of bony abnormality, such as sacralization

of the fifth lumbar vertebra, or a separate first sacral piece which may be called a sixth lumbar vertebra. Sacro-iliac subluxation from trauma or due to the flat back acquired on an operating table under a prolonged anæsthetic is another cause of pain in the region of the lower part of the buttock which may be associated with pain down the back of the thigh. This pain, which is sometimes agonizing, may be due to the lumbosacral cord being pressed on by the sharp edge of the sacrum at the sacro-iliac joint. These cases are sometimes dramatically cured by manipulation under an anæsthetic.

Bony disease in the pelvic bones, such as Paget's disease affecting the ischium, or other tumours of the pelvic bones or in the pelvis, secondary malignant growths in the lumbosacral spine, or tumours in the lumbosacral cord or cauda equina, have all to be considered in the diagnosis of obscure cases of pain in this region. What may be called malignant sciatica is by no means an uncommon sequel of carcinoma of the breast.

In the diagnosis of these cases care must be taken to examine for muscular wasting in the leg or thigh, for patches of anæsthesia, or for alterations of the deep reflexes. If the knee-jerk is diminished or lost we know at once that the case is not a true sciatica, but that the anterior crural system is involved. Lumbar puncture and examination of the cerebrospinal fluid may give a clue in tumours low down in the spinal canal involving the sacral cord or cauda equina. Besides the more usual forms of tumour such as fibroma or sarcoma, cysticercus, lipoma, and chronic arachnoiditis, with cystic formation, may be mentioned, and herniation of the body of an intervertebral disk. These will scarcely show in radiographs, except with careful lipiodol pictures. The pressure may be found to be below normal, and there may be other evidences of spinal block, with high protein content in the fluid.

Tuberculous caries of the ilium or sacrum, with or without psoas abscess, or intrapelvic pressure from a high forceps delivery in childbirth may press upon the nerve and cause severe dropped foot, with anæsthesia of the sciatic distribution. I saw one such case, with left sciatic paralysis, in which delivery was accomplished under an anæsthetic. There was also paralysis of the musculo-spiral nerve on the right side from arm pressure against the edge of the table. The diagnosis which had been sent up with the case to hospital was 'crossed paralysis'.

Osteo-arthritis of the hip-joint may cause pain not only in the region of the hip and knee but even down to the ankle, and true sciatic neuritis may result from spread of the inflammatory reaction around the hip-joint to the sciatic nerve, which passes only half an inch behind it. In all cases it is advisable to examine the movements of the hip-joint to make sure that they are free. In many cases of sciatica, whether of the low or the high type, the pain will be increased by stretching the nerve, as by flexing the hip with the knee straight. This sign is usually known as Lasègue's sign, which is precisely the same as Kernig's sign in meningitis. Patients suffering from sciatica usually prefer to lie on the opposite side, with the affected knee slightly drawn up, and a pillow should be given to separate the knees, with a curved support under the bedclothes to prevent the weight pressing on the foot.

POINTS IN DIAGNOSIS

There are many points, therefore, to attend to in the diagnosis of a case of apparent sciatica when first presented: knee-jerks and Achilles jerks should be compared with those on the other side, muscular wasting should be looked for, and the sensation also tested. The hip-joint should be moved and the nerve stretched gently to look for increase of pain, and a rectal examination is generally advisable. If the knee-jerk is diminished, tabes dorsalis may be thought of and the pupils examined, or alcoholic or diabetic neuritis looked for.

Tenderness over the notch in the buttock and along the upper part of the nerve is common in the low type of sciatica, but usually this is not present in high

sciatica with contralateral scoliosis. There is no wasting of muscles in the common rheumatic types of sciatica, either of low or high type, except in the very chronic cases of many months' or years' duration, when the nerve may be actually shrunken and cord-like. In such extreme cases it will be necessary to cut down upon the nerve and scarify it longitudinally in order to free the adhesions.

TREATMENT

The treatment of sciatica will vary according to the type. In the low type of sciatica, especially when there is tenderness at the notch and the patient leans towards the affected side, rest in bed should be insisted on, and local heat by radiant-heat lamp or infra-red rays may give considerable relief. Some practitioners favour short-wave radiotherapy, and I have seen this successful when most other treatments have failed, but as a rule I have not found diathermy to be of much service. Galvanism often aggravates the pain in the acute stage of sciatica, though in the chronic stage it sometimes may prove valuable. Moist hot packs, such as cataplasma kaolini or mud packs, or mud baths at Harrogate or at the Continental spas such as Pistany or Acqui, may be given in chronic cases where the patient is able to walk. The very acute cases must be treated in bed. Local applications of liniments, such as A.B.C. or methyl salicylate, may be applied in addition to hot packs, and for the acute pain analgesics should be used freely. Compound aspirin tablets with or without codeine, and in more severe cases pyramidon, heroin, and medinal cachets, or actual injections of omnopon or morphine, may be necessary to tide the patient over the severe attacks of pain and to produce sleep.

Two methods of massive injection of novocain and saline may be used with great benefit in a large proportion of cases, and sometimes rapid cure may follow their use. In the low type of sciatica such as that following lumbosacral fibrositis, in which there is tenderness on pressure over the nerve in the buttock and at the notch, the injection may be made into the nerve trunk itself at the notch and a second injection at the level of the small trochanter. This is not the place to give the details of the method of injection, but 2 c.cm. of 2 per cent novocain are first injected into the nerve and then 80 to 100 c.cm. of normal warm saline. A second injection may be of service a few days later. This method of injection of the nerve was first used in 1902 by Lange.

Another method of epidural injection was advocated in 1901 by Sicard—by injection of novocain and saline up to 100 c.cm. into the sacral canal through the sacro-coccygeal foramen. Owing to the sacral canal not communicating with the intrathecal space, which ends at the level of the lower end of the first piece of the sacrum, the saline forces its way upwards outside the theca, stretching the sacral and even the lumbar roots as they emerge. This method is probably of greater service in the high form of sciatica. Other solutions are sometimes used, such as 10 to 20 c.cm. of a 40 per cent solution of antipyrine, as Feilung recommends.

For obstinate chronic cases Dogliotti's method of intraspinal injection of absolute alcohol has been recommended; but it is a dangerous treatment, and should not be undertaken by a novice. I have used it with success in a case of eight years' severe constant pain and misery due to sacralization of the fifth lumbar vertebra, procuring several months' complete relief of pain, though for the first fortnight sphincter paresis was present.

Fixation of the limb with a Liston splint along the side has been advised, but I do not recommend it, as patients usually cannot bear to be kept in a fixed position for many hours. Another form of fixation is sometimes of benefit—namely, a plaster jacket, applied with the patient slung up by the armpits and head so as to stretch the spine, the plaster bandages being applied from under the armpits to just below the level of the great trochanters. The advantage of a plaster jacket is that the patient can get about and even

attend to his business, in reason, though it has certain obvious disadvantages. An alternative is keeping the patient confined to bed, with the feet raised on six-inch blocks, and extension to the spine applied by means of leather anklets attached by cords running over pulleys fixed on the foot of the bed to separate shot-bags weighing 6 to 8 lb. A certain amount of counter-extension by padded axilla rings tied to the head of the bed will probably be necessary in addition to the raising of the foot of the bed on blocks. This method of extension does not preclude a certain amount of lateral movement or rotation by the patient, and the weights are easily detached at night or for toilet purposes.

If a plaster jacket is applied it is very important that proper extension to the spine, including the neck, should be arranged for during the whole period of the fixing of the plaster and its setting. This is best done by the use of Sayre's extension apparatus, with tripod and pulleys fixed to leather hands for the chin and occiput, and axilla pads. The patient is slowly and carefully raised by the pulleys on to his toes, most of the weight being taken by the arms. If raised in this way the patient can remain quite comfortably semi-suspended while plaster bandages are applied from axillæ to trochanters over a stockinet vest, the bony prominences, such as the iliac crest, being well padded with adhesive felt, known as elephant plaster.

CONCLUSION

Briefly, therefore, the treatment of an acute severe sciatica should be complete rest in bed, with local anodyne liniments and cataplasma kaolini, and sometimes local heat by infra-red rays. Analgesic drugs must be given, such as aspirin, phenacetin, and caffeine tablets, with or without codeine or opium, and even morphine or heroin injections may be required for a few days. Sleep may be obtained by the use of $7\frac{1}{2}$ grains of medinal with two veganin tablets. Massage must never be used in the acute stage. Later in the more chronic stage massage may help, and galvanism, diathermy, or local heat should be tried. If these fail, massive injection of the nerve or epidural injection by novocain and saline, and extension by weights attached to anklets, with counter-extension at the axilla, should be tried. If these give only temporary relief, it may be advisable to fix a plaster from the axillæ to the trochanters so that the patient may be able to get about and attend to a certain amount of business.

Glandular Fever

By F. R. B. ATKINSON, M.D.

(From *Medical Press and Circular*, Vol. CCI, 18th January, 1939, p. 52)

Synonyms.—Many names have been given to this disease, the two chief of which are infective mononucleosis and monocytic angina. Description: Glandular fever is characterized by three chief symptoms, fever, enlargement of the lymphatic glands, and a lymphomononucleosis.

History.—In 1885 Filtaow described a disease, which is now recognized as glandular fever, and in 1888 Korsakoff shortly mentioned the condition. In 1889 Pfeiffer first made use of the term glandular fever for a disease, which caused enlargement of the cervical glands, accompanied by fever, pains in the limbs, and general unrest, with recovery in a few days, and it is from this date the history of glandular fever begins. In addition to this slight form, Pfeiffer described acute cases which lasted longer and were associated with an enlarged spleen and liver, and a third form he called subacute, in which the disease especially attacked abdominal glands. At the same meeting, Heubner reported the presence of exanthemata, and in two cases nephritis occurred. Shortly afterwards, Starck reported on two cases, and drew attention to the frequent implication of the submaxillary as well as of the cervical glands. He was the first to mention a convulsive form of cough, which suggested affection of the

bronchial glands. One of the cases suffered also from hæmorrhagic nephritis during the course of the disease. In the same year Rauchfuss described two cases, one in a boy and one in his sister. In 1894, Desplats was the first to report swelling of the axillary and inguinal glands. In 1896 West described the first epidemic of the disease. For many years opinions varied as to glandular fever being a disease *sui generis*, and it was not until 1920 that Sprunt and Evans reported on six cases in adults under the title of infectious mononucleosis and submitted the blood to careful examination. The blood findings were the same in all the cases: the white blood cell count was normal at first and was followed by a leucocytosis, the mononuclear cell being markedly increased. They pronounced in favour of an infectious origin and considered the disease a clinical entity, and this view was supported by Tidy and Morley, and repeated by Tidy and Daniel. They also believed glandular fever and infective mononucleosis were identical. In 1930 Glanzmann published an important monograph under the name of lymphæmoid glandular fever, and in the same year Radford and Rolleston reported two cases which were at first diagnosed as typhus fever, and drew attention to the presence of a positive Wassermann's reaction with no evidence of syphilis, and Parkes Weber noted the same occurrence. In 1932 Lehdorff and Schwarz went minutely into a description of the disease in all its aspects in the most complete monograph extant. In this year Paul and Bunnell discovered the presence of heterophile antibodies and suggested they were pathognomonic of the disease, a view opposed by Wolf. In 1933 Cardelle y Penichet found protein therapy, especially of casein, gave first-rate results in cutting short the time of the disease and preventing complications. In 1936 Tschilow noted the presence of glandular fever after quinine poisoning, and Sucher and Schwarz the association of the disease with meningoencephalitis. Gsell reported on the presence of serous meningitis in glandular fever. Lumbar puncture revealed increased pressure of the spinal fluid, which contained almost entirely lymphocytes, an increased amount of albumin, with a mastix reaction deviation to the left and a double curve by the gold sol test.

Symptomatology.—The chief symptoms of glandular fever are enlargement of the glands, fever and a lymphomononucleosis of the blood with atypical young cells. Pfeiffer, as we have seen, only described swollen cervical glands, but it is now generally recognized the whole lymphatic system may be involved, including the spleen. Transitional cases also occur, in some of which there may be no fever and in others no detectable enlargement of the glands. Glanzmann distinguishes five phases in glandular fever:—

(1) *Incubation.*—This period lasts from 7 to 8 days in most cases. (2) *Prodromal stage.*—This is usually short, but may be prolonged from 2 to 4 weeks, during which time the patient suffers from tiredness, malaise, pains in the abdomen, in the region of the navel, loss of appetite, outbreaks of perspiration, and a change in the colour of the face is often noted. (3) *Febrile stage and initial symptoms.*—Six different forms are described: (a) *Septic type.* High fever suddenly occurs but there is no evidence of an angina or disease of the internal organs. Vomiting is frequent, with pains in the head and limbs, and there is a great tendency to sleep. Swelling of the glands may be slight, but the spleen may become very large. The fever usually lasts from 2 to 5 days, but may only exist for one, or may continue for more than 14 days. (b) *Anginose form.* Here the fever comes on suddenly and may be high, and the condition is ushered in by swelling of the tonsils with or without a deposit similar to diphtheria. (c) *Pharyngeal type.* The follicles of the pharynx are enlarged and red, and all the glands may in time become enlarged. (d) *Thoracic type.* Catarrh of the upper air passages and bronchitis, with a cough similar to that met with in pertussis, are the chief signs. (e) *Abdominal form.* In this type the symptoms suggest an acute abdominal disease such as appendicitis, with the presence of fever

and colicky pains. The mesenteric glands first become swollen, followed by those of the axillary, inguinal and the cervical regions. (f) Slow, mild type. Only slight fever is present, or it may be absent altogether. The glands become swollen, but the child hardly feels ill.

(4) *Stage of glandular swelling.*—The glands begin to swell in all parts of the body, or the enlargement may be confined to one set of glands. The spleen may become increased in size and sometimes the liver.

(5) *Convalescence.*—The fever disappears and all the subjective symptoms vanish, but the enlarged glands may still be felt in many instances. The blood changes are slow in returning to the normal. Recurrences of fever may take place. The forms described above are now generally confined to three, the lympho-glandular, the anginose and the leukæmoid. The first is by far the commonest form and is the classic type described by Pfeiffer, who, however, did not describe enlargement of any of the glands except those of the neck. It occurs chiefly in children. In the anginose form, the affection of the pharynx dominates the picture. This form is more often found in elder children and young adults. The leukæmoid form of Lehdorff and Schwarz is a severe, septic, systemic disease, with a marked lymphomonocytic blood reaction predominating. This is the form that is often mistaken for leukæmia.

The initial symptoms of glandular fever are fever, enlargement of the lymphatic glands, especially first the cervical and catarrh of the pharynx. Pains in the back of the neck precede the swelling of the glands. Epistaxis is an early symptom and marked asthenia, especially in adults, is very characteristic. Headache and pains in the bones are very frequent. Vomiting may be so severe that no food can be taken. Cerebral symptoms are very frequent: somnolence, but more often excitability, sleeplessness, nightmare, delirium at night; signs of meningismus are not rare.

Fever.—The absence of fever is very rare, although such cases have been described in a few patients. It shows no distinctive type and thus differs from the exanthemata. It is common for the temperature to rise quickly to 101°F. or 102°F., and remain at this height for 1 to 5 days, with morning remissions, and then quickly or slowly to become normal. In other cases, the fever may persist for two or three weeks. In septic cases it may remit or intermit, similarly as in malaria and in other cases, the evening temperature may reach over 102°F. for some days. A temperature similar to that met with in typhus fever has been described. The highest temperature recorded seems to be 105.8°F. The fall of the fever is usually by lysis, but in some very rare cases by crisis. Relapses are common, and Glanzmann has found them to occur with a rise of temperature from the 9th to 10th, 13th to 14th, and 19th to 24th days. Fever and the glandular swellings are not dependent on each other: the rise of temperature may occur with swelling of the glands, may precede it, and be for a time the only symptom of the disease, or generalized swelling of the glands may precede the fever by days or weeks. It is also noteworthy that the severity of the glandular swelling is not related to the fever. In the severe, septic cases with high fever, the glands are often quite small, and conversely, the temperature may be slight with great enlargement of the glands.

Lymphadenopathy.—The cervical glands are usually the first to become enlarged, followed by those of the axillary, inguinal, and other glands. The left cervical glands are much more often the first attacked than the right. Abscess formation, though known to occur, is very rare. It is uncommon for the axillary glands to be primarily affected, as in Glanzmann's case, and the same applies to the inguinal glands, but the same author has seen such a case in a boy aged 12 years. In the thoracic form there is a primary affection of the mediastinal, peribronchial and perihilar glands, giving rise to fits of coughing similar to those met with in pertussis, and in some cases accompanied with hæmoptysis, so that the suspicion of tuberculosis is aroused.

Enlargement of the spleen.—The spleen is palpable in about one-third of the cases: in some cases the

splenomegaly is almost the only morbid sign present, and enlargement of the glands is almost absent, and to this form the name 'splenic' has been given. The enlargement may remain for years.

Hepatomegaly.—In a number of cases the liver is enlarged, with the presence of urobilinogen in the urine. Jaundice has also been described in the adult, but Glanzmann was the first to find it in the child. To the cases with only enlargement of the spleen and liver, Glanzmann has given the name 'visceral' form.

The blood.—The chief characteristic of the blood is a high percentage of mononuclear cells, 80 to 95 per cent. In some cases there is a decreased number of leucocytes. There is a relative and absolute increase of lymphocytes, and a large number of immature and pathological forms of cells with a marked tendency to plasma-cell change in all stages of maturity. The number of white corpuscles varies between 10 to 25,000, and only rarely reaches 50,000 and more. For only a short time is there a neutrophile leucocytosis, which reaches its maximum between the 5th and 9th day of the disease, then decreases in absolute value, but remains as a relative lymphocytosis for a long time. The eosinophiles never disappear altogether. The erythrocytes are not altered in number and the percentage of hæmoglobin is normal, so that there is no anemia. The degree of the blood changes is not a measure of the severity of the disease. The condition is slighter and quicker recovered from, the more marked at the beginning is the pathological mononucleosis, while in severe cases the mononucleosis only develops slowly. There is a certain parallel between the degree and the extent of the glandular swellings and the intensity of the mononucleosis: very marked swelling of the glands may occur with only a moderate pathological mononucleosis, and, on the other hand, slight enlargement of the glands may be present with a very marked blood finding.

Glandular fever may appear epidemically or sporadically. It has been described in nearly all parts of the world: England, France, Germany, Italy, Switzerland, Russia, China, Australia, and in the United States of America.

Sex.—The male sex is much more frequently attacked than the female. In an epidemic in Bern, Glanzmann noted 160 cases, 96 of which were males and 64 females. In an epidemic affecting students Baldrige found 38 were males and 12 females. Konigsberger's figures were 15 boys and 3 girls and in an epidemic in the Falkland Islands, Moir states 52 were males and 36 females. The environment seems to have nothing to do with the presence of glandular fever, which has been called in America the students' disease.

Age.—The disease is one of children and young adults, but has been met with in more elderly people. It chiefly occurs between the ages of 5 and 8 years. Glanzmann found the majority of cases were to be seen between 2 and 8 years of age, with a maximum at 5 years. Tidy and Morley found 80 per cent of the cases affected children between 5 and 9 years. It is very rare in babies, but Glanzmann records a case in a baby of six months, which seems to be the youngest described, as I cannot corroborate the statement of Tidy and Morley, copied by Glanzmann, that Schäffer reported a case in a child four months of age, or their other statement that Robertson published a case in a child aged six months. The oldest case seems to be that of a man, aged 70 years, reported by Moir.

Sporadic cases occur at any time of the year, but epidemics are most frequent in the spring and autumn.

Complications.—In addition to those already mentioned, conjunctivitis, which is common, and parotitis should be included. When the latter is present, the condition suggests mumps. Stomatitis and pharyngitis are quite frequent. The angina may be catarrhal, follicular and lacunar, pseudo-membranous, diphtheroid and ulcerative.

Exanthemata.—These are not infrequent, but are not the essence of glandular fever. All sorts of rashes have been described: urticarial, scarlatinal, morbilliform, lichenoid. A rash similar to erythema multiforme, rubella and typhus has been reported.

Pathogenesis.—The actual germ has not been determined. A protozoon, a bacterium called *monocytogenes hominis*, spirochete, a fuso-spirillosis, and the streptococcus have been found.

Contagion.—The sporadic cases are not as a rule contagious. In epidemics, many cases may occur in the same family. How long glandular fever is infectious is not certain; Tidy thinks up to a week after the fever has disappeared.

Prognosis.—This is always good. The four cases of death reported were before the hæmatological era and are doubtful cases.

Prophylaxis.—Isolation of the patient for 14 days is advised by Tidy and Daniel, three to five weeks by Glanzmann.

Treatment.—The treatment is symptomatic. For combating the fever, quinine is the best remedy, and Glanzmann uses suppositories of hydrobromide of quinine, 0.1, and pyramidon, 0.02 to 0.1, at noon and in the evening. Rest in bed should be enjoined whilst the fever lasts. Aspirin has been used at the beginning to produce sweating. A fluid diet is advisable in the febrile stage. For disinfection of the nasopharynx, instillation of 3 per cent collargol solution is valuable, and if the nose is badly obstructed 1 per cent solution

of supra-renal with half of boracic water; in small children, camphor or eucalyptus oil (1 per cent). In older children, gargles should be employed (1 per cent peroxide of hydrogen) and painting in the pseudo-diphtheroid forms with 5 per cent chromic acid, and in the fuso-spirillary forms, painting the ulcer of the tonsils with neo-salvarsan, 0.15 to 10.0 glycerine. In marked stomatitis, the lips should be painted with 1 per cent solution of permanganate of potash. When the glands are large, antiphlogistine should be used and in cases where they are small warm fomentations with boracic acid. Glandular swellings which are obstinate in clearing up do well under yatrien-casein injections; in children up to two years, 0.2 to 0.3; up to six years, 0.3 to 0.5; older children, 1.0 c.c.; one to three injections. Rubbing with soft soap with 5 per cent ichthyol added may also be used. The best results are provided by irradiation with the quartz lamp. In convalescence, cod-liver oil, malt extract with iron, a mixed diet of meat, vegetable and fresh fruit are indicated. If an abscess forms, punctiform incisions suffice. In the thoracic form, sedatives for the cough should be given, and in the abdominal form suitable diet, belladonna to stop the spasms, and moist, warm camomile compresses.

Reviews

SURGICAL PATHOLOGY.—By William Boyd, M.D., LL.D., M.R.C.P.Ed., F.R.C.P. (Lond.), Dipl. Psych. F.R.C.S. Fourth Edition. 1938. W. B. Saunders Company, Philadelphia and London. Pp. 886, with 476 illustrations and 15 coloured plates. Price, 45s.

PROFESSOR BOYD needs no introduction, and much less so his book on surgical pathology, which is being extensively used in all the English speaking countries, both by students and post-graduate workers. In the present edition, which has come out after 5 years, the author has thoroughly re-written the subject-matter in view of the rapid progress which has been made in the domain of pathology. He has also introduced a considerable number of new subjects of enormous surgical importance. The replacement of the introductory chapter, which is an excellent philosophical discourse on surgery in relation to pathology, will certainly be welcome to all readers. The style and presentation have been maintained fully up to the standard of Professor Boyd's works. To mention just a few, the chapters on the thyroid gland, breast, gall-bladder, bone, and stomach may be read with interest.

The reviewer is one of the many lovers of Professor Boyd's works and having studied his book very minutely he would like to put forward some of his personal comments for the improvement of the work. The most important point to be raised is the question of diagrams which are obviously, even to a casual observer, lifeless and artificial. A large number of them are not taken from actual morbid tissues, but have been drawn by hand. Even such common things as granulation tissue, tubercle, inflammation, common neoplasms, etc., which may be obtained in any number in any pathological unit to illustrate the typical histological pictures, have been treated in a diagrammatic manner. While the writer has spent so much money to illustrate by coloured pictures, conditions like gangrene of the foot, histology of gas gangrene, etc., he has effected economy in illustrating *Spirochaeta pallida* in a primary syphilitic lesion stained by Levaditi stain and by omitting to include any picture to illustrate the various types of pituitary adenomas. These are bad economy. Although this work is passing through the fourth edition, Professor Boyd has not made any sincere effort to replace his borrowed diagrams by his own originals. This is certainly a legitimate demand of the many readers of this book. Amongst his borrowed pictures, the number of which

is by no means small, the author has still retained some which are only of historical interest and should be replaced by good modern ones. Lastly, there are some diagrams in the text which can hardly be made out while there are others which are wrongly interpreted. On page 114, under blastomycosis, there is a picture which shows long filaments or hyphae. In page 127, under pulmonary embolism there is a picture which no one can make out, while the one in page 128 shows a very unreal picture of pulmonary infarct. In page 425, under tuberculosis of the kidney, there is a picture from which hardly any idea can be had of miliary tuberculosis of the organ.

A few points in the subject-matter may be mentioned to draw the attention of the writer for improvement. In dealing with some chapters, he has shown undue brevity. Although the author belongs to the country where the great Dr. Cushing did his monumental work on pituitary adenomas, he has spared just one page for their description in his book. Similarly, he does not seem to appreciate the work of Masson on carcinoid tumours of the appendix as he has chosen not only a poor picture of that morbid condition (*vide* page 340), and he has called it carcinoma of the appendix—a term which should no longer be kept in pathology. In discussing the pathogenesis of tetanus, he mentions that the toxin 'spreads to the sensory side of the cord'. His terminology in some places requires revision. For instance, no one should talk of 'carcinoma simplex', a term which conveys no meaning.

The above points are mentioned with a spirit of constructive criticism and should on no account be taken to lower the excellence of this admirable handbook which should adorn every library and which should be in the hands of every student and practitioner alike.

M. N. D.

CRANIO-CEREBRAL INJURIES: THEIR DIAGNOSIS AND TREATMENT.—By Donald Munro, A.B., M.D., F.A.C.S. 1938. Oxford University Press, London. Pp. xxviii plus 412. With 62 illustrations. Price, 21s. Obtainable from Oxford University Press, Bombay and Calcutta

THE aphorism of Hippocrates that 'no head injury is so trivial as to be neglected or so serious as to be despaired of' still holds good. With the mounting toll of street accidents head injuries present a greater degree of complexity, adding to the responsibilities of the

general surgeon. In 1932, it was estimated that the approximate number of fractures of the skull which occurred in the United States was around 112,000. In this book an effort has been made to present all known diagnostic and therapeutic methods, which are physiologically sound and, from practical experience, known to be effective. We have no doubt that this monograph on cranio-cerebral injuries will be accorded a warm welcome.

There are fourteen chapters in this book and 393 pages of printed matter. It is very creditable that, within such a small compass, room has been found for so much pertinent and valuable material. The arrangement of the subject-matter deserves special mention and is certain of grateful appreciation by all surgeons. General principles of treatment are first carefully described. Then there are two chapters on 'special non-operative methods' and 'special operative methods' of treatment. These are followed by two informative chapters on 'the non-operable' and 'the operable' groups of cranio-cerebral injuries. Here, complications of head injuries have been carefully discussed and the next chapter is devoted to the consideration of complications due to necessary treatment. There are also two chapters on convalescent care and first aid. Cranio-cerebral injuries in the newborn have not been omitted from special consideration.

This book is replete with valuable practical hints. Regarding the vexed question of 'position', the author states that in conscious and co-operative patients, the position which is most comfortable is the most useful. The printing, get-up and illustrations are all excellent. At the end of each chapter there is a complete bibliography and a useful index is appended.

We strongly recommend this book to the notice of the practising surgeon and the general medical practitioner, as it is one which they can ill afford to be without.

P. N. R.

STUDIES ON THE PHYSIOLOGY OF THE EYE.—

By J. Grandson Byrne. (Re-issue with supplement and new index.) 1938. H. K. Lewis and Company, Limited. Pp. xii plus 440. Illustrated. Price, 40s.

THIS volume deals with the original research work carried out by the author at different laboratories in England, on the continent of Europe and in America during the past twenty years. It consists of forty-four chapters divided into four parts. Part one deals with the paradoxical pupillary phenomena following lesions of the afferent paths. Part two with the preliminary palpebral widening; paradoxical palpebral and lens phenomena and inherent tonus phenomena. Part three with stimulation experiments and their effects. Part four with the inherent pupillary constrictor tonus and the mechanism of the still reaction, sleep, dreams, hibernation, repression, hypnosis, narcosis, coma and related conditions. In addition there is a supplement which deals with the effect of stimulation of the cortex cerebri upon the effector mechanisms which mediate movements of the iris and membrana tympani.

The book represents a tremendous amount of experimental work and forms most interesting reading. It is written in a clear, simple style and is provided with forty-eight illustrations.

To students of neurology and ophthalmology we recommend it as a book of reference.

E. O'G. K.

REFRACTION OF THE EYE INCLUDING ELEMENTARY PHYSIOLOGICAL OPTICS.—

By C. Goulden, O.B.E., M.A., M.D., M.C. (Cantab.), F.R.C.S. Second Edition. 1938. J. and A. Churchill Limited, London. Pp. xv plus 271, with 181 illustrations. Price, 12s. 6d.

THIS is the second edition of this book and as would be expected in the highly specialized branch of ophthalmology with which this volume is concerned there are no fundamental changes in the new edition. The whole of the text has however been revised. The

book consists of seven chapters on optics, the optical constants of the eye, the eye as an optical apparatus, errors of refraction, the ophthalmoscope, retinoscopy and finally the function of convergence and muscular anomalies. There is in addition a bibliography and 181 illustrations.

As the book is likely to be used extensively in India the reviewer would like to point out that the accommodative power of the eye diminishes much more rapidly in Indians, Anglo-Indians and Europeans born and brought up in India in contrast to people living in non-tropical climates. This is probably due to alteration in the consistency of the lens occurring at an earlier age. The average emmetrope in India becomes presbyopic at the age of 38 years.

The book is primarily written for the student preparing for the diploma in ophthalmology of the conjoint board of England but the author covers a wide field and so it will be of benefit to the ophthalmologist as well. The subject-matter has been presented in a simple practical way and on the whole the book is excellent. We strongly recommend it and only hope it will be widely read and if so it must lead to the general improvement in the art of refraction work in India.

E. O'G. K.

GARDINER'S HANDBOOK OF SKIN DISEASES.—

Revised by John Kinnear, T.D., M.D., M.R.C.P. (Ed.). Fourth Edition. 1939. E. and S. Livingstone, Edinburgh. Pp. xv plus 239, with 16 coloured plates, 5 from Dufayocour photographs. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 7.

THIS is the first occasion on which the reviewer has encountered this book and it must be admitted that its small size rather prejudiced him against it as it was felt that skin diseases could not be dealt with in such a small compass.

Perusal of the book, however, brought about a complete change of opinion because it was found that all the really essential knowledge for the general practitioner is contained in it. In addition to a large number of carefully selected photographs there are 16 coloured plates most of which are good, but in a certain number there is rather an excess of rose pink coloration in the lesions.

The arrangement is good and easily followed, this applies particularly to the chapter on toxic dermatoses in which the author has included dermatitis herpetiformis, erythema multiforme, etc., which in the reviewer's opinion is their correct place.

It is a book that can be strongly recommended to general practitioners as one that will supply them with the necessary information for treatment of any case that is not of sufficient severity to send at once to a dermatologist.

P. A. M.

THE SURGERY OF PAIN.—By René Leriche, M.D. (Lyon), LL.D. (Glas.), F.R.C.S. (Eng.) (Hon. Causa), etc. Translated and edited by A. Young, B.Sc., M.B., C.M., F.R.F.P.S.G., F.A.C.S. (Hon.), M.D., Strasbourg (Hon. Causa), etc. 1939. Baillière, Tindall and Cox, London. Pp. xix plus 512. Illustrated. Price, 21s.

It is needless to say that the appearance of a new volume by Professor Leriche may rightly be regarded as an event of outstanding importance in the medical world. There is added fascination in the fact that this book is entitled 'The Surgery of Pain' and of pain as the surgeon sees it. It will be generally agreed that no one is more eminently fitted than Professor Leriche to handle this difficult problem. It is a matter of gratification that the translation from the original French was carried out by no less an authority than Professor Young of Glasgow, to whom our best thanks are due.

The origin of this book is associated with the name of Professor Charles Nicolle, at whose invitation these lectures were delivered in connection with the Chair

of Medicine at the Collège de France at Paris. It may be recalled that Professor Nicolle succeeded to the chair, once occupied by Jaennec, Magendie, Claud Bernard, Brown Séquard and d'Arsonval. In this book Professor Leriche gives the complete dramatic story of the inception and development of the surgery of the sympathetic nervous system. There are altogether 14 chapters, covering such diverse and difficult subjects as 'pain-malady' trigeminal and facial neuralgias, causalgia, pains due to vaso-constriction, angina pectoris and inoperable malignant neoplasms. Pain is treated in this book, not as a symptom but as a disease—'pain-malady'. Such a view, of course, is revolutionary and is liable to be stoutly opposed by physiologists. Neither is the surgeon spared, a common type of facial neuralgia is designated as the 'syndrome of multiple needless operations'. It is refreshing to read that the surgeon's art 'does not as a rule long retain anything that is too strictly instrumental. For their proper use, instruments require their inventors'. It is explained that Raynaud's disease is brought about by hyper-excitability of the sympathetic. In the treatment of angina pectoris, one encounters the general therapeutic problem of arteritis and vaso-motor disturbances. One of the most fruitful contributions by Professor Leriche to surgical advance is the demonstration of the 'diagnostic value of the abolition of pain by regional novocainisation'. This is only one of the many notable features of his work.

This is, indeed, a book to possess and study.

P. N. R.

THE PHARMACOLOGY AND THERAPEUTICS OF THE MATERIA MEDICA.—By W. J. Dilling, M.B., Ch.B. (Aberd.), M.P.S. (Hon.). Fifteenth Edition. 1939. Cassell and Company, Limited, London. Pp. x plus 600. Price, 10s. 6d.

This book has gone through 15 editions and 23 reprintings; it has served two generations of medical students and doctors; and there seems every reason of predict that it will serve a third generation equally well.

The last edition was published six years ago so that many additions will be found in the present one. The *Addendum* to the B.P. was published in 1936, and all the new drugs that appeared in this are dealt with fully in this edition, through intelligent anticipation on the part of the author most of them had already been included in the 1933 edition.

A number of drugs that have not yet acquired pharmacopœial rank are included, such as nicotinic acid, mandelic acid, zinc protamine insulin, various hormones, the sulphanilamide group, and snake poisons.

The information given is for the most part concise and accurate. The author says, quite rightly, that quinine is not a perfect prophylactic in malaria but from the rest of the paragraph one gathers that he has not fully appreciated the difference between clinical prophylaxis and true causal prophylaxis.

It is a book that we can strongly recommend.

YOUR CHEST SHOULD BE FLAT: THE DEEP CHEST MAKES BETTER SOIL FOR TUBERCULOSIS.—By S. A. Welsman, M.D., F.A.C.P. 1938. J. B. Lippincott Company, Philadelphia and London. Pp. xvii plus 145. Illustrated. Price, 9s. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 6

The author, who is Assistant Professor of Medicine, University of Minnesota, has recorded his observations on several hundreds of normal and tuberculous chests and on 20,000 Minneapolis public school children. Besides the determination of the thoracic index (i.e., the ratio of the depth of the chest to its width), the length-width index, the length-depth index and the size of the subcostal angle, the vital capacity was measured.

The author refers to the popular and erroneous idea that the healthy chest is round and deep and the tuberculous chest flat. By a careful study on a significantly large number of cases from infancy onwards he has shown that the opposite is true, namely, the

tuberculous chest is round and deep, while the normal chest is flat and wide with an index between 60 to 70 per cent. The infantile chest is round but in healthy individuals it gradually flattens up with age owing to various factors. The chests which do not flatten with age have been shown to be more prone to disease. The thoracic index has been found to be higher in tuberculous chests and still higher in chronic bronchitis and asthma.

It has been shown that the thoracic index falls in the case of boys from 72 at the age of 5 years to 67 at the age of 18, while in girls it ranges from 71 at the age of 5 years to 70.4 at the age of 18. Up to the age of puberty there is no very clear difference in the chest contours of the two sexes. After puberty, however, the boys' chests are flatter than those of girls of the same age. It decreases steadily in both sexes as height increases and also as vital capacity increases. It has further been shown that environment has a definite influence on chest development, children from good environments showing on average a much better type of development than children from poor environments.

From the data collected and analysed by the author, especially on tuberculin-tested individuals and on tuberculous patients, he thinks that the deep, narrow chest offers a more favourable soil for the development of tuberculosis than does the flat, wide chest. The following factors have been generally noticed in association with the deep chest:—weight and height below normal for age, poor socio-economic environment, lower than normal standing in school work and tendency to positive tuberculin test.

The author considers that the normal development of the chest and the early correction of physical defects are likely to be vitally important in preventing tuberculosis and emphasizes that, for early detection and correction, the tuberculin test and the chest measurements should be a routine procedure in the medical examination of children. Diet, environmental adjustments, suitable physical exercise and a periodic medical check-up for all children have been advised as some of the correctional procedures.

The author has devoted much time and labour to this subject. As the method does not require any elaborate equipment and complicated procedure, suitable indices may be found for each country and applied in preventive medicine. As the book is written in simple and non-technical language, doctors as well as educationists may peruse the book with great interest and profit. The printing and get-up do credit to the publishers.

A. C. U.

FORMULARY OF THE JUMNA DISPENSARIES, ALLAHABAD—BASED ON THE BRITISH PHARMACOPŒIA, 1932 AND SUPPLEMENT 1936. Compiled by the Staff. 1938. Published by Dr. D. N. Forman, Jumna Dispensaries, Allahabad. Pp. 138

The formulary of the Jumna Dispensaries, Allahabad, is based on the British Pharmacopœia 1932 and its supplement 1936. The book is divided into several sections and contains many valuable prescriptions used in different diseases. The appearance of the volume is good and there are footnotes and enough space for additional notes. It would have been better if the posological table (B. P. 1932) was also included in the book. The book will serve as an useful guide to medical men and hospitals.

M. N. R. C.

HISTOLOGICAL TECHNIQUE FOR INTRACRANIAL TUMOURS.—By Dorothy S. Russell, M.D. (Lond.). 1939. Oxford University Press, London. Pp. vii plus 71, with 6 plates. Price, 7s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta

This is a book on pure technical methods. Differential staining in histological technique is a very important part in the study of histopathology and this is specially applicable in the case of brain tumours. But there must be caution in the application of these

special methods as pointed out by the writer, because of the many pitfalls the novice may encounter. The authoress is a well-known technician and she has done a great service to beginners by publishing this small volume so that they may not be misled. All the details including the handling of the specimens, fixation of tissues, methods of embedding, composition of reagents, etc., have been described. There is a welcome departure from previous books on technical methods, viz. the inclusion of photomicrographic plates, which will have wide appreciation.

This will be an extremely useful book and should certainly find a place in every histological laboratory.

B. P. T.

HANDBOOK OF SANITARY LAW FOR THE USE OF CANDIDATES FOR PUBLIC HEALTH QUALIFICATIONS.—By B. B. Ham, M.D., D.P.H. (Camb.). Twelfth Edition. 1938. H. K. Lewis and Company, Limited, London. Pp. xxi plus 355. Price, 7s. 6d.

This book has been regarded as a valuable compendium of sanitary law by the students qualifying for the D.P.H. in England.

Although the students preparing for the diploma in public health in this country read the Indian laws (provincial and municipal), they have to keep themselves informed of the current English laws as well. The book will serve that purpose admirably well, especially because all the latest English acts and orders have been incorporated in it.

A DESCRIPTIVE ATLAS OF RADIOGRAPHS: AN AID TO MODERN CLINICAL METHODS.—By A. P. Bertwistle, M.B., Ch.B., F.R.C.S.Ed. Fourth Edition. 1939. Henry Kimpton, London. Pp. xxxii plus 576, with 852 illustrations. Price, 42s.

It is just about three years ago that we had the pleasure of reviewing the third edition of this book whose object is to demonstrate to the clinician what great assistance properly taken radiographs can be in practically every department of their work.

The book is not the unaided work of the author, because in the beginning there is a long list of contributors who have helped him by supplying case records and pictures. The result of this is that the wide selection made available by the pooled results of many workers has led to the collection of practically perfect examples of the radiologists' art for all possible conditions.

The fourth edition is an improvement on the third because certain of the figures have been replaced by even better ones and there are nearly sixty more of them.

It is a very easy book from which to extract information because facing the illustrations there are brief notes giving the essential points of the history of the case from which the radiograph has been made, and a further aid is in many cases a small line drawing of the principal structures in the picture to serve as a reminder. But it must be admitted that most of

the figures are so clear that these line replicas are hardly necessary.

It is a useful and instructive book from which much may be learned by the easy and pleasing occupation of simply examining perfect reproductions of remarkably clear radiographs.

POCKET MEDICAL DICTIONARY.—By the late G. M. Gould, A.M., M.D. Eleventh Edition of over 40,000 Words. Revised by C. V. Brownlow. 1939. H. K. Lewis and Company, Limited, London. Pp. 1066. Price, 10s. 6d. Bound limp. With Thumb Index—12s. 6d.

A DICTIONARY of medical terms is essential to the students of medicine and Gould's *Pocket Medical Dictionary* is a well-known publication of proven worth.

This dictionary contains a vast amount of valuable information. There are over 40,000 terms used in medicine and the allied sciences. The appendix contains complete tables of arteries, nerves, muscles, chemical elements, hormones, micro-organisms, prefixes and suffixes, phobias, signs and symbols, etc., also dose lists of drugs and incompatibilities and a veterinary dose table, both in English and metric measures.

The reviewer would suggest that more attention should be paid to certain terms used in tropical medicine; e.g., the definition of kala-azar given in this book is 'An epidemic fever of Assam', which is obviously very unsatisfactory; and there is no mention of Napier's aldehyde test or Chopra's antimony test, though there are to be found, 'Froehde's reaction for proteids' and 'Justus's test'.

Terms like 'loculation syndrome' or 'Troin's syndrome', 'myocardosis' should have been included. The term 'nephrosis' has been defined as 'any kidney disease'.

These few deficiencies do not, however, rob the dictionary of its usefulness. The reviewer strongly recommends this book to medical students and practitioners.

OTHER BOOKS RECEIVED

Medical Practice in Residential Schools: A Manual for Medical Officers and Others.—By F. G. Hobson, D.S.O., D.M., F.R.C.P. 1938. Published by Oxford University Press, London and New York. Pp. xvi plus 284. Illustrated. Price, 10s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta.

Uterus Masculinus: A Critical and Constructive Essay Concerning the Genitalia and Their Homologues.—By J. A. Leo Magee, M.B. Published by Messrs. H. K. Lewis and Company, Limited, London. 1939. Pp. 95. Price, 5s. 6d.

Play Therapy in Childhood.—By C. H. Rogerson, M.D. (Lond.), M.R.C.P., D.P.M. 1939. Published by Oxford University Press, London: Humphrey Milford. Pp. 64. Price, 3s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta.

Abstracts from Reports

KING EDWARD VII MEMORIAL PASTEUR INSTITUTE AND MEDICAL RESEARCH INSTITUTE, SHILLONG. THE TWENTY-FIRST ANNUAL REPORT FOR THE YEAR ENDING 31ST DECEMBER, 1937

Antirabic section.—There has been no change in the method of preparation or the scheme of treatment. The use of Paris virus was continued during the year

and a carbolized 5 per cent sheep brain emulsion issued as the vaccine.

Treatment was carried out at Shillong and its centres and altogether 2,093 persons applied for treatment. Of these 1,806 completed the full course of treatment and 121 absconded before the completion of treatment. There were 163 advice cases who did not receive any treatment or discontinued treatment after two or three days because they were not at risk and treatment was considered unnecessary.

The following case has been included as a case of hydrophobia as the evidence on the whole seems to favour this diagnosis:—

Child aged 4 bitten on the head by a dog on 2nd July, 1937. Wounds cauterized with carbolic within two hours and patient given a full course of class IV antirabic treatment. On 29th September, 1937—nearly two and a half months after completion of treatment—developed hydrophobia and died on 8th October, 1937. The history as given by the physician attending the case was as follows:—

29th September, 1937.—Fever and loss of appetite.

4th October, 1937.—Slight spasm of the muscles of deglutition but able to drink water.

5th October, 1937.—Temperature 100.4, pulse 116. Restless; able to stand and walk.

7th October, 1937.—Temperature 100.2, pulse 116. No paralysis of limbs. Can swallow fluids.

8th October, 1937.—Temperature 97, pulse 140, vocal cords paralysed, right leg paralysed; retention of urine; can drink water. Died at 8-15 p.m.

The interesting features are:—

(1) The exceptionally long duration of illness—nearly 10 days from the initial onset of symptoms.

(2) The absence of convulsions and 'hydrophobia'—the patient was able to swallow fluids throughout her

The following is a summary of the activities of the society during the year 1937:—

1. *Staff*.—During the year the staff has numbered 36, including seven sub-assistant surgeons, Public Health Department, who had been deputed for one year's training in malariology.

2. *Training class*.—The annual eight weeks' course in malariology was held from 19th July to 18th September and was attended by 13 qualified medical men and one man who had previously received training in malariology. Of these, five were from the Public Health Department, five from tea estates and four private nominees. Eleven candidates passed the examination set at the end of the course.

3. *Malaria surveys*.—One new survey of a large *bhil* area adjacent to tea estates and a populous town previously surveyed has been undertaken during the year in order to determine the limitations of application of control measures.

Four tea estate surveys were completed during the year and recommendation for control measures submitted.

4. *Treatment schemes*.—The following table shows the results so far obtained in the Doom Dooma Cinchona-Plasmoquine Treatment Centre:—

OCTOBER–NOVEMBER–DECEMBER

Year	Number examined	Spleen		Number examined	Parasites	
		Number enlarged	Spleen rate		Number with parasites	Parasite rate
1	2	3	4	5	6	7
1932 ..	253	143	56.5	277	113	40.7
1933 ..	195	106	54.3	195	34	17.4
1934 ..	178	27	14.6	178	12	6.7
1935 ..	359	48	14.1	339	49	14.4
1936 ..	263	55	20.9	263	108	41.0
1937 ..	466	68	14.6	466	63	13.5

illness and the sight or feel of fluids did not bring about spasms in the throat or general convulsions.

(3) The long incubation period for a class IV bite in a young child.

Vaccine section.—The total quantities of vaccines issued during the year were:—

1. Cholera vaccine .. 425,443½ c.c.
2. T.A.B. vaccine .. 7,316½ e.e.
3. Influenza vaccine .. 15,060 c.e.

Bacteriophage section.—The total issues during the year amounted to 401,884 doses. Of this 117,040 doses represent the free supply to Nowgong and Habiganj for the first three months of the year. The balance was supplied as follows:—

Government institutions in the province	99,840 doses
Tea gardens	97,396 "
Railways	5,296 "
Missions	1,776 "
Private persons and institutions	29,184 "
Municipalities and local boards	26,592 "
Other governments ..	24,760 "

This year we have issued 587,436 doses less than in 1936 and the difference is due to the discontinuance of the free supply of bacteriophage to the experimental areas of Nowgong and Habiganj.

ASSAM MEDICAL RESEARCH SOCIETY

For the seventh year since its inception, the society has had a full year of activity. The activity of the workers has been confined to problems on the subject of malaria only, because of the limitation of funds made available by subscriptions.

The parasite rate shown for 1936 suggests that during a year of exceptionally high endemicity, infections are still being readily acquired in spite of the treatments given. The spleen rate, however, during 1936, remained comparatively low. Subsequently, in 1937, the spleen rate was again reduced to 1934-35 levels and in 1937 the parasite rate was also reduced to the level previously found.

Four groups of villages were selected for treatment of all malaria cases where parasites were demonstrable on blood examination, with reinforced cinchona febrifuge. The village treatment schemes were financed jointly by the Local Board concerned and the Government of Assam. Data collected on the efficacy of the treatment schemes will be presented.

5. *Entomological*.—Routine examinations carried out between 1st January and 31st December have included the identification of 140,733 anopheline larvae, 7,553 adults and 598 adult dissections.

6. *Blood examinations*.—During the year, 12,657 blood specimens have been examined and 3,519 or 27.8 per cent were found positive for malaria parasites.

7. *Experimental malaria control*.—In two groups of villages selected for experimental cold weather and pre-monsoon anti-larval control, it is still too early to give a significant evaluation of the efficacy or otherwise of the methods applied, which have been based on researches made by the society's workers but they suggest that in the Surma Valley villages the methods applied may prove to be efficacious when established over a significant period of years.

In the Brahmaputra Valley group, the indices indicate that the anticipated malaria control has so far failed.

The failure cannot, however, be attributed to the period of anti-larval control measures as the villagers, although they agreed in 1935-36 not to do so, cut a bund of the river in the cold weather 1936-37 which caused water to flow over approximately 370 acres of rice land thus making adequate economic malaria control an impossibility.

8. *Researches*.—Experiments on the efficacy of Pyrocid 20 as an insecticide were carried out by using Pyrocid 20 in kerosene in dilutions of 1-40, 1-35, 1-30, 1-25 and 1-20 in rooms of 1,500 cubic feet capacity using $\frac{1}{2}$ oz. of the dilution per experiment. Five experiments were made with each dilution where 100 adult anophelines (*A. maculatus* and *A. annularis*) were liberated prior to spraying with the diluted Pyrocid 20. Results were tabulated 20 minutes after exposure to the vapour in terms of numbers of anophelines dead and numbers stupefied. To determine whether those only stupefied after 20 minutes' exposure would recover, they were examined again after 24 hours when, without exception they were found to have died.

9. *Provincial malaria control*.—In co-operation with the Public Health Department and the Provincial Advisory Malaria Committee, supervision and recommendations have been given for nineteen anti-larval and five treatment schemes where surveys have been completed by the society.

CHOLERA ENQUIRY UNDER THE INDIAN RESEARCH FUND ASSOCIATION

Following the recommendation of the Cholera Advisory Committee of the Indian Research Fund Association the Field Unit at Habiganj was closed on 31st March, 1937, and the work of the enquiry has since been chiefly directed to basic laboratory research at the Pasteur Institute, Shillong.

These researches although of great interest and value are of too highly technical character for inclusion in this abstract so those interested are referred to the original report.—Eaton, I. M. G.

REPORT OF THE HAFKINE INSTITUTE, BOMBAY, FOR THE YEAR 1937. BY LIEUT.-COLONEL S. S. SOKHEY, I.M.S., DIRECTOR

GENERAL REVIEW

DURING the year under review (1937), the limited resources of the institute were almost entirely devoted to the routine production of large quantities of prophylactic vaccines. The institute produces Hafkine Plague Vaccine in large quantities to meet the needs of the whole of India, and prepares cholera, typhoid and antirabic vaccines for use in the Province of Bombay. In addition, the institute functions as the Provincial Bacteriological Laboratory and does a considerable amount of diagnostic work for the government hospitals. Though the institute has no resources of its own for conducting researches, important investigations in plague and pharmacological studies of synthetic anti-malarials were conducted with the generous aid of the Indian Research Fund Association. A number of voluntary workers also carried out a number of researches.

Plague vaccine.—In the case of broth vaccines, those incubated at 27°C. are more potent than those incubated at 37°C. While in the case of agar vaccines, those incubated at 37°C. are more potent than those incubated at 27°C. Killing of cultures by the application of heat at 55°C. for 15 minutes gives better vaccines than when the cultures are killed with phenol or formalin.

One new observation of some interest has emerged. As reported before, we had developed a method of rendering plague strains avirulent by repeatedly sub-culturing them on agar slopes at weekly intervals and incubating them at 37°C. By this method we had rendered avirulent strain 120/5H. The live avirulent vaccine used in our previous study was made from this strain and it proved to be possessed of very high protective value. During the year we rendered avirulent another strain, strain I, by the same method.

But the live avirulent vaccines prepared from this strain have proved to be almost entirely devoid of any protective power. This would seem to show that avirulent strains differ in their antigenic value. We propose to study this point more fully. The behaviour of avirulent strains in this respect should be compared with the behaviour of virulent strains. We have not noticed any measurable differences in the antigenic value of the large number of different virulent strains we have used in our work. If a suitable vaccine is made from a fully virulent strain it always seems to possess a very high protective power.

Anti-plague serum.—Production of the serum on the lines reported before was continued, but no opportunity arose during 1937 of testing the serum in the field. However, early in 1938, a small epidemic occurred at Bettiah, Bihar, and we were enabled to deal with 124 cases, and those treated with serum gave a percentage mortality of 27 and the controls a percentage mortality of 65; the patients were taken alternately for serum treatment and as controls without selection.

Epidemiology of plague.—An interesting fact has emerged from our studies which seems to have a bearing on the mechanism of pandemics of plague, how they come to an end and how they start again after the lapse of time. The Indian Plague Commission working in 1907, when plague was still raging in Bombay, found that rodents responsible for the spread of plague in the city were *Rattus rattus* and *Rattus norvegicus*, which formed over 99 per cent of the rat population. They found these species to be highly susceptible. They also found that *Gunomys varius* was not a common rodent in Bombay city and that it formed only 1 per cent of the rat population. We, working in 1937, find that *Rattus rattus* and *Rattus norvegicus* together form only about 70 per cent of the rat population and *Gunomys varius* accounts for the remaining 30 per cent. More interesting still, *Gunomys varius* is highly susceptible to plague infection while the other two species are now highly resistant, that is, the erstwhile agents of the spread of the disease have become resistant and are being replaced by a species which is highly susceptible.

DEPARTMENT OF PHARMACOLOGY

The department continued its investigations into the pharmacology of synthetic anti-malarials and its studies in acetylcholine. The previous observation that plasmoquine did not affect the course of pregnancy in any way was extended by the observation that the placenta acted as a filter and prevented the drug from getting into foetal circulation. By an ingenious technique it was shown that while toxic doses of the drug definitely affected the maternal heart, it showed no effect in the heart tracing of the foetal heart. The measurement of the concentration of the drug in the maternal blood stream and in the foetal circulation confirmed the above observation. Similar studies on the action of atabrin are also in progress.

Studies in acetylcholine have yielded further interesting facts. The rôle played by this substance in the transmission of nerve impulses at nerve ends in muscles is well known, but it was doubtful whether it played a similar rôle in the central nervous system at the ends of the afferent nerves. Dr. Dikshit has been able to obtain some experimental evidence that acetylcholine is liberated in the central nervous system when afferent nerves are stimulated.

With a further generous grant from the Indian Research Fund Association the department was strengthened by the employment of a highly trained research chemist, Dr. B. K. Nandi, who has facilitated the pharmacological studies of plasmoquine by developing a new test for quantitative and qualitative estimation of the drug in tissues. Two voluntary research workers Dr. H. S. Mahal and Miss K. Bhagvat made studies in choline esterase and developed an enzyme method for the estimation of adrenaline.

This department is still entirely maintained by the Indian Research Fund Association and is engaged primarily in researches on synthetic anti-malarial drugs,

but it is hoped Government will take over the department and strengthen it to enable the department to take up work in connection with the control of the sale of drugs in the Province.

BIOCHEMICAL DEPARTMENT

The department besides its routine work continued work on establishing normal clinical standards for Indians. For establishing red cell and hæmoglobin standards for normal Indian men and women 121 men and 101 women between the ages of 18 and 30 years have been examined. Hæmoglobin determinations were made by Van Slyke oxygen capacity method, a method which yields very accurate results. An average of 15.37 gm. of hæmoglobin per 100 c.c. of blood for men and an average of 12.99 gm. for women were obtained. Contrary to all expectation these averages tallied exactly with similar hæmoglobin averages worked out in America for American subjects in spite of the dissimilar dietetic and climatic conditions of Indian and American subjects. This observation points to the possibility of there being a physiological constant for hæmoglobin. The subject is being studied.

TRIENNIAL REPORT ON THE WORKING OF THE CIVIL HOSPITALS AND DISPENSARIES IN THE MADRAS PRESIDENCY FOR THE YEARS 1935 TO 1937

At the commencement of the triennium, there were 1,356 medical institutions of all classes in this Presidency as against 1,283 at the end of the triennium, i.e., 31st December, 1937. The decrease is mainly due to a number of medical institutions having been transferred to the new Orissa Province.

The number of in-door patients treated during the year 1937 was 280,150 as compared to 255,358 in 1936 and 245,590 in 1935.

The total number of out-door patients treated in all the hospitals and dispensaries in the Presidency during the year 1937 was 17,179,284 (7,960,550 males and 4,341,961 females and 4,876,773 children) as compared to 16,032,812 (7,482,765 males, 4,022,425 females and 4,527,622 children) in 1936 and 16,570,958 (7,788,602 males, 4,015,155 females and 4,767,201 children) in 1935.

The daily average number of in-patients treated during the year 1937 was 12,917.20 as compared to 11,656.03 in 1936 and 11,244.20 in 1935. The daily average number of out-door patients treated in the medical institutions during the year 1937 was 123,625.88 as against 109,226.04 in 1936 and 112,479.96 in 1935. The increase in the daily average number of in- and out-patients apparently indicates the popularity of the allopathic medical institutions.

Among the various diseases treated in all classes of hospitals and dispensaries, those that accounted for the largest number are shown below:—

Diseases of the digestive system (excluding diarrhoea, dysentery and tumours)	2,415,375
Diseases of the eye	1,545,527
Diseases of the respiratory system except pneumonia and tuberculosis of the lungs	1,380,494
Ulcerative inflammation	1,343,753
Diseases of the ear	1,196,685
Injuries (local and general)	1,191,752

The Rural Medical Relief Scheme which was inaugurated in this Presidency in the year 1925 continued to work with success during the triennium under report. During the earlier part of the triennium, Government could not give effect to the opening of a number of new rural dispensaries due to financial stringency. As the conditions improved, their opening and operation were sanctioned by Government in the last quarter of the year 1937. There were 428 rural dispensaries in this Presidency at the close of the year 1935, 397 at

the close of the year 1936 and only 404 at the close of the year 1937.

With a view to widen the scope of the maternity relief work and to enable the rural population to avail themselves of the services of trained and qualified midwives for labour cases in a large measure, Government have undertaken to meet the subsidy paid to the midwives, from the provincial funds and enhanced the provision for appointments of increased number of midwives in rural areas. The Rural Medical Relief Scheme having taken strong root and its value having become recognized by the rural population, the usefulness and the popularity of the scheme are bound to increase in a wider scale in future.

Malaria.—The total number of patients treated for malaria during the year 1937 was 1,107,937 with 297 deaths as compared to 999,612 with 230 deaths in 1936 and 1,069,669 with 268 deaths in 1935.

Dysentery.—The number of cases of both amœbic and bacillary dysentery treated during the year 1937 was 317,568 with 655 deaths as against 302,632 with 545 deaths in 1936 and 302,077 with 531 deaths in 1935.

Kala-azar.—The number of patients treated in 1937 was 2,517 with 19 deaths as compared to 1,919 with 13 deaths in 1936 and 2,130 with 13 deaths in 1935.

Enteric fever.—Twenty-two thousand seven hundred and seventy-three patients were treated in the year 1937 with 719 deaths whereas the number of patients treated in 1936 was 21,919 with 588 deaths and in 1935, 20,856 with 577 deaths.

Labour cases.—One hundred and twenty thousand seven hundred and nineteen labour cases were conducted during the year 1937 in all classes of medical institutions of which 100,779 were normal and 19,940 abnormal. The corresponding figures for 1936 and 1935 were 104,171 (88,916 normal and 15,255 abnormal) and 106,823 (90,910 normal and 15,913 abnormal), respectively.

Tuberculosis.—The total number of patients treated in the Tuberculosis Institute, Egmore, in the year 1937 was 11,985, the daily average attendance being 213.37. The Tuberculosis Clinic opened in the Victoria Caste and Gosha Hospital, Triplicane, during the year 1935 continued to work during the whole of 1937. The lady assistant surgeon of the institute was deputed to work in the clinic thrice a week. The total number of patients treated in this clinic during 1937 was 319, the daily average attendance being 11.10. The patients requiring treatment in the Tuberculosis Institute were put on a waiting list and it was frequently found necessary to give some active treatment to some of the cases who were waiting for admission into the hospital so induction of initial A.P. was commenced with five beds from June 1937. The Tuberculosis Clinic of the King George V Anti-Tuberculosis Sub-Committee which has been located in the institute's premises has been doing work in contact collaboration with the institute and rendered valuable service.

The total number of patients treated in the Tuberculosis Hospital, Royapetta, Madras, during the year 1937 was 733 as compared with 914 in 1936. The decrease was due to one of the male wards having been occupied by the Public Works Department for over two months in connection with certain special repairs.

The Tuberculosis Sanatorium at Tambaram which was taken over by Government in 1937 commenced to work under this department from 12th April, 1937, with an accommodation for 40 patients. One hundred and two cases were admitted during the year of which 62 were discharged and 40 remained at the close of the year.

Leprosy.—The leprosy work during the triennium under report made steady progress. The leprosy campaign which owes its rapid progress to the support of Government was also taken up by local boards and the public. Non-official organizations were formed to further the campaign and appeals to the public for funds were well responded to. The number of clinics opened, the total attendance and the number of cases

treated during the triennium under report were as follows:—

Year	Number of clinics	Total attendance	New admissions
1935 ..	440	808,746	37,399
1936 ..	446	788,396	33,097
1937 ..	445	777,188	33,038

About 20 clinics were transferred to Orissa Province during 1936.

Medical education.—The medical education in the colleges and schools continued to be efficient during the triennium and the percentage of passes was satisfactory. In Madras a physical director was appointed for both the Medical College and the Stanley Medical School. He is also looking after the games and other activities of the sports of these institutions. Special tutorial classes for coaching the students for final F.R.C.S. Examination were held in the Madras Medical College in 1937.

Honorary medical officers.—Applications were invited for appointment of honorary medical officers during 1937 and suitable candidates were appointed in the hospitals where their services were required. The response from women medical practitioners to take up honorary posts was, however, very poor. Under the reorganization scheme for appointment of honorary medical officers in the place of paid officers, the former will be paid a graded honorarium from Rs. 20 to Rs. 100 per mensem in both the teaching and general cadres and the tenure of such honorary officers will be limited to five years.

Nurses and midwives.—The reorganization of the nursing service in this Presidency and the introduction of male nursing service is under consideration of Government. There is a great need for the development of the nurses' and midwives' profession though this Presidency may be said to have advanced in this respect much more than most of the other provinces in India. The appointments of nurses in many of the hospitals in the mofussil are inadequate and the need for additional staff is being keenly felt. The course of training of nurses for midwives has been extended from one year to 18 months. The proper training of nurses is handicapped for want of sister tutors although a large number of candidates who are educationally qualified are seeking admission in the training schools for nurses.

A REPORT OF THE SIXTY-FOURTH YEAR'S WORK IN INDIA AND BURMA OF THE MISSION TO LEPERS. SEPTEMBER 1937 TO AUGUST 1938

The main statistics for 1937 are as follows: On 31st December, 1937, there were 7,544 patients resident in the mission's homes in India and Burma; there were also 813 healthy children of lepers, for whom the mission was providing either homes, or means for their separate care. In addition there were 2,030 patients and 152 healthy children in other homes, not belonging to the mission, to which substantial financial aid was given. A total of 10,590 men, women, and children were therefore securing the benefits of the mission's ministry. And in addition an almost equal number of out-patients suffering from leprosy—10,444—were receiving medical treatment. So that the mission's activities reached in one way or another over 20,000 people. On the financial side the total expenditure in 1937 was Rs. 8,12,209. This was made up of Rs. 4,35,646 received from contributions and Rs. 3,76,563 from Government or Local Board grants. Of the private contributions for the maintenance of the work it is well

to remember that, deeply grateful as we are for those received from friends in India, the great majority of such funds come from distant countries. We recognize, of course, that the grants from public sources represent, if in an indirect way, the contributions of the people of India and Burma, and for this substantial help we express our appreciation. We are also particularly grateful for substantial funds given for building purposes from sources in India.

There has been the fiftieth anniversary of the establishment of the mission's largest home, Purulia, with over 800 patients resident to-day. During its fifty years of ever-growing service over 13,000 lepers have found shelter and friendship there. At Purulia the first home in India for the healthy children of lepers was built; Purulia was one of the first homes to engage in organized out-patient clinic work (and there is now a weekly attendance of over 400). In many ways this home has been in the vanguard of advance. And we would pay a special tribute to the present superintendent, the Rev. E. B. Sharpe, who for the last seventeen years has with such devotion given himself to the work.

This year, another home, hospital and clinic has been built and opened at Zamuradganj just outside Fyzabad.

At the formal opening in August of this year, the speech of His Excellency Sir Maurice Hallett, at that time Governor of the United Provinces, reveals something of the progress which has been made in knowledge and outlook since the early days of the mission, and indicates the conditions under which new work may begin to-day, as compared with fifty years ago:

'The history of the care and treatment of leprosy contains many pages filled with surpassing heroism and self-sacrifice. It is only however of very recent years that medical science has been able to hold out any hope of cure to those infected with this disease, or any means of checking it from spreading, other than by the method of segregation. Those infected were previously condemned to a life-long isolation from their uncontaminated relatives and friends, and to the prospect of prolonged and inevitable suffering. Modern medical science has many great achievements to its credit and one which has been accomplished by the patient efforts of large numbers of workers has been to demonstrate that the disease is not incurable if it is treated by certain new methods in the earlier stages. The disease can, therefore, be controlled not merely by the defensive method of segregation but by the offensive method of early diagnosis and treatment; and fresh hope is given of ultimate success in banishing it from India as it has been banished from the Western world. The time when that may be possible is no doubt still far distant, but the creation of centres such as this will bring it nearer and make possible the early treatment of sufferers. The experience gained at institutions such as this will do much to increase the knowledge of our medical experts and they will, I am confident, be able to discover further preventive and curative measures which will be of the greatest benefit to humanity. The cause is one which cannot but claim our sympathy, and our gratitude to those who have helped to create this institution.'

It is also a matter for encouragement that whereas fifty years ago fresh schemes awaited the generosity of friends abroad, the initiative and funds for fresh work is now more frequently coming from within India.

In actual methods of treatment there have been no special developments. But the fact that increasing numbers of homes are being asked to allow Government or Local Board medical officers to undergo special training in them emphasizes the growing attention which is being given to the disease by health authorities. Results of treatment have not been spectacular, but the figure of 768 patients, in whom the disease has been arrested before deformity has begun, forbids us to be discouraged and challenges us to renewed effort.

STATISTICS OF TREATMENT, 1937

In-patients

Inmates under treatment at end of year ..	7,432
Inmates who received treatment for three months and upwards	9,549
Much improved	2,520
Slightly improved	2,605
Became worse	588
Had to stop treatment	162
Apparently stationary	1,045
Died or left	1,480
Cases arrested <i>without deformity</i> ..	768
Cases discharged <i>without deformity</i> ..	554
Cases arrested <i>with deformity</i> ..	381
Cases discharged <i>with deformity</i> ..	122
Cases arrested in a previous year but relapsed during the year	58

Out-patients

Number of out-patients treated ..	10,444
Cases improved	1,417
Cases arrested or became symptom-free ..	230

Correspondence

CHRONIC SNAKE-BITE

To the Editor, THE INDIAN MEDICAL GAZETTE

Sir,—I had often heard of persons bitten by a snake getting the habit of being bitten again and again, but I never believed it, till the following case came under my personal observation, which I think will be of some interest to your readers:—

P. L., aged about 28 years, a relative who is working as a compounder with me and lives in my house, was bitten by a snake in July 1937. He was again bitten in June 1938; the snakes were killed by him in both of these instances, on the spot. Then, a snake started biting him every month, and the time of biting was four or five days before or after the full moon. It is biting him still at regular intervals. The house in which he lives is a brick building of two storeys with brick floors on the lower storey and cement floors in the upper storey. He was made to sleep in the upper storey, but was bitten in spite of these precautions.

I have twice seen the snake coming to bite him alarmed by the house dog who intercepted the snake by his furious barking. In one instance the snake was killed by me, but the patient was bitten the day following at a village four miles away where he had gone to see a patient.

The only effect of the bite is the passing of bloody urine and shooting pains along the whole length of his spine for about four days.

He has gone to different places to consult native experts reputed to be curers and has even crushed the head of a live snake between his teeth, which was advised as the best antidote for future bites, but all in vain.

These repeated bitings and the perpetual fear of being bitten is having psychological effects on his general health by now.

I must earnestly request that you will kindly help me in recommending any treatment for this complaint. I have never come across any literature on this subject anywhere up to now.

In case nothing is known to present-day medical science, I would suggest that you will give publicity to this to get views of your readers.

Yours, etc.,

ISHAR DAS, M.P.L.

MARKED WASTING AND RETARDATION OF DEVELOPMENT RESULTING FROM LACK OF ESSENTIAL AMINO ACIDS IN THE DIET

To the Editor, THE INDIAN MEDICAL GAZETTE

Sir,—From time to time I get cases in the Out-Patient Department of the Bai Jerbai Wadia Hospital for Children, Bombay, some of which have been referred to me by the doctors for the treatment of paralysis. All the children that I have so far seen have been between the ages of 2 to 5 years. There has been an invariable history of the child never having yet learnt to walk. I have so far seen twenty such cases, 15 of whom have been derived from the Gujarati Hindu community, one South Indian child, and four Parsee children. A few of these could not even sit, whereas four had learnt to stand a little before they came up for examination.

All these children have been very thin and relatively dwarfed for their age. They are also slightly anæmic. The most outstanding feature, however, is the profound hypotonia, which, with the extreme thinness of the limbs, leads the unwary clinician to diagnose the condition as one of infantile paralysis. This extreme hypotonia allows exaggerated movements at the joints, and in those who can stand, the limbs sag inwards and backwards, producing a considerable degree of genu-valgum or genu-recurvatum or both. The feet collapse under the weight and assume an extreme valgus position, the child actually standing on the inner borders of the feet. If the child has been standing for some time, the feet develop a fixed valgus deformity and small wonder then, that, under such circumstances, one is beguiled into diagnosing the condition as one of polio-paralysis.

Patient examination of each individual muscle however shows that power is still present in each one of them and that the child is only weak, not paralytic. Radiological examination shows a marked degree of decalcification and thinning of bones with mild grade of rachitic changes at their ends.

All these cases occurred in families extremely poor. They were obviously cases of nutritional deficiencies, especially inadequacy of essential amino-acids, such as glycine, tyrosine, tryptophane, and cysteine. They are not cases really of paralysis or paresis for:

- (a) the condition is always bilateral and symmetrical,
- (b) some power is still present in all the muscles and
- (c) complete cure is always obtained by supplying the necessary ingredients lacking in the diet.

They are all due to lack of essential amino-acids in the diet for:

- (1) it is well known that these acids are absolutely essential, alike for our growth and for existence,
- (2) our body cannot evolve them and depends for their supply on ingested proteins, especially animal-proteins, which almost alone are what the physiologists term 'adequate proteins',
- (3) sixteen out of twenty cases occurred in Hindus, who, besides being strict vegetarians, were so poor that they could not even provide themselves with adequate supply of milk,
- (4) in the somewhat similar condition of muscular dystrophies, exhibition of glycine brings about a definite improvement, though, of course, it is temporary, and
- (5) finally, administration of these amino-acids in the form of an elegant preparation 'Novo-tropon' brings about a complete cure in every one of these cases.

I treated my first two cases by advising mixed diet or more liberal use of milk coupled with Calcipot-D (Torponwerke-Cologne). It was at this stage that I came to know about 'Novo-tropon' (Troponwerke-Cologne) and that it contained the amino-acids, as one of its chief ingredients. I started prescribing it along with Calcipot-D, for similar cases that came up to me later on, and I must admit, it has yielded results beyond my expectations. The rapidity with which the patients improve is very gratifying. In about a month's

time all the skin-folds fill out, the anæmia clears up and the child walks independently and usually with confidence.

The existence of these cases in our midst and the rapidity with which they improve with Novo-tropon brings home to us the dire necessity for a nation-wide propaganda to abjure silly vegetarianism in favour of more sensible and certainly far more scientific mixed diets on Western lines. I presume that such cases exist in far greater number in urban than in rural areas, where the poor parents are likely to have access to purer milk supply for their children than in towns. In India, where strict vegetarianism is still almost a part of religion, for millions, the need for milk supply, adequate both in quantity and quality for the children of the poor, is of national importance.

To sum up, there is a group of cases which seem to form a clinical entity by themselves.

These are children, between the age of 2 to 5 years, who have not yet learnt to walk. They are slightly anæmic but markedly wasted and show a profound grade of hypotonia.

They are apt to be mistaken for cases of polioparalysis and so correct treatment is unfortunately delayed.

They are really due to lack of essential amino-acids through failure of a purely vegetarian diet to provide the necessary quantity of adequate proteins.

A change in national outlook towards our diet is very desirable and until such a change is brought about and gross poverty eradicated, the need for some such preparation as Novo-tropon will continuously arise.

Yours, etc.,

R. J. KATRAK, B.A., N.S.C. (Bom.),
M.Ch. Orth. (L'pool), F.R.C.S. (Eng.).

URTICARIA FOLLOWING PRONTOSIL RUBRUM TABLETS

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—In connection with comments on a case report about 'urticaria following Prontosil Rubrum tablets' appearing in March 1939 issue of the *Indian Medical Gazette*, I wish to express the opinion that the time of appearance of urticaria depends mainly on the sensitiveness of the patient rather than the mode of administration of the drug. In a case of abortion recently treated by me, urticaria developed within 30 hours during which period 2 doses of 5 c.cm. each of the red solution had been injected intramuscularly. No further injection was given and the patient put on prontosil album orally, which was fully tolerated.

Yours, etc.,

HUKAM CHANDRA, M.B., B.S., F.C.M.S.,
Assistant Surgeon, In-charge.

CIVIL HOSPITAL,
MAILSI, DISTRICT MULTAN,
PUNJAB,

THE EFFECT OF M. & B. 693 ON PNEUMONIA TREATED IN CIVIL HOSPITAL, MERCARA

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—During the last four months the pneumonia cases treated in this hospital have fallen into two groups, i.e., those who have come from coffee estates whose owners have agreed to pay for M. & B. 693 treatment, and those who have come from estates whose owners have not done so.

There were 18 cases in the former group who received M. & B. 693. Of these three died giving a

mortality rate of 17 per cent. Two of the cases who died were moribund when admitted and the M. & B. 693 could not have had time to take effect. This leaves only one case which died in spite of adequate treatment with M. & B. 693. This gives a mortality rate of 1 in 16, i.e., 6 per cent.

Of the 37 cases who did not receive M. & B. 693, 15 died which gives a mortality rate of 41 per cent which is usual for this hospital where pneumonia is almost invariably complicated by chronic malaria and hookworm.

There was no difference in the type of patient in the two groups and there was no difference in the line of treatment given apart from the addition of M. & B. 693.

It thus appears that the addition of M. & B. 693 to the treatment of pneumonia in this hospital reduced the mortality rate from 41 per cent to 6 per cent.

Yours, etc.,

G. P. CHARLEWOOD,
CAPTAIN, I.M.S.,
Civil Surgeon.

COORO,
'MERCARA',
7th April, 1939.

CHRONIC ULCERATIVE COLITIS

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—I have gone through the able article on 'Chronic ulcerative colitis' by Colonel Chopra and Dr. Roy published in the *Indian Medical Gazette* of February 1939 with interest. I agree with all that has been stated therein. But I miss very much the mention in it of 'Bale' fruits as an adjunct to treatment although 'Isabgul' has justifiably been mentioned. 'Bale' renders the stool formed and gives that sensation of ease and satisfaction after passing it which is a very welcome factor in these patients who suffer from the oppressive feeling of never being able to empty their bowels completely.

During the season the pulp of the ripe fruit is eaten as it is or mixed with a little sugar to taste, or as 'Sharbat' preferably on empty stomach in the morning or in the late afternoon. When not yet ripe the green fruit (middle-aged) is cracked, burnt over the fire to the extent that the hard shell is charred and rendered brittle and the pulp is then scooped out, mixed with a little sugar, and eaten. But 'Bale' fruit, ripe or green, is not obtainable throughout the year. Therefore in order to provide against the off-seasons of the year my patients make and preserve for themselves thin slices of green fruits in quantity. The middle-aged fruit is chosen. Its hard outer shell is shaved off, the core is then cut in round discs of about one-fourth inch in thickness, dried carefully in the sun and stored for future use. A few of these, according to necessity, are boiled in water and the softened discs are smashed up with a little sugar and eaten.

In my experience there is another point in favour of 'Bale'. In a few cases I have noticed colitis alternating with naso-pharyngeal catarrh or bronchitis. The cycle is somewhat like this a few days of colitis followed by a few days of catarrh or bronchitis. 'Bale' in addition to relieving colitis renders catarrh or bronchitis less liable to return, at least in the usual frequency, that is to say, the remissions are longer.

Yours, etc.,

S. C. SEN,
Civil Surgeon.

RAJSHAH, I,
27th March, 1939.

[We have shown the above letter to Colonel Chopra who makes the following comments:—

"Our experience is that neither 'Isabgul' (*Plantago ovata*) nor Baël fruit (*Aegie marmelos*) do much good in chronic ulcerative colitis. The writer evidently has in his mind chronic dysentery of amoebic or bacillary origin."—EDITOR, I. M. G.]

Service Notes

APPOINTMENTS AND TRANSFERS

Colonel H. J. M. CURSETJEE, D.S.O., to be Officiating A. D. M. S., Western Independent District. Dated 15th April, 1939.

Colonel E. G. Kennedy reverted to military employ, with effect from the 20th April, 1939.

Brevet-Colonel B. C. Ashton to be Officiating O. C., C. I. M. H., Dehra Dun. Dated 12th March, 1939.

Lieutenant-Colonel R. H. Malone, Pathologist, Rangoon General Hospital, on proceeding on leave, made over and Lieutenant-Colonel G. C. Maitra, Director, Pasteur Institute, Rangoon, received charge of the duties of Pathologist, Rangoon General Hospital, on the afternoon of the 31st March, 1939, in addition to his own duties.

Lieutenant-Colonel J. G. McCann to be O. C., I. M. H., Shillong. Dated 18th March, 1939.

Lieutenant-Colonel J. E. Amsley to be Officiating O. C., I. M. H., Karachi. Dated 4th March, 1939.

Lieutenant-Colonel S. M. A. Faruki to be Officiating O. C., I. M. H., Rawalpindi. Dated 5th March, 1939.

Lieutenant-Colonel B. Z. Shah returned from leave and has been appointed Civil Surgeon, Belgaum, with effect from the forenoon of 26th March, 1939, *vice* Captain A. A. Pular, transferred.

Lieutenant-Colonel J. C. Pyper, O.B.E., an Agency Surgeon, is posted as Residency Surgeon, Hyderabad, with effect from the forenoon of the 29th March, 1939.

Major R. McRobert received charge of the duties of Medical Superintendent, Rangoon Dufferin Hospital, on the afternoon of the 6th April, 1939, from Lieutenant-Colonel M. L. Treston.

Lieutenant-Colonel A. Ba Thaw, on relief, resumed charge as Assistant Inspector-General of Civil Hospitals, Burma, on the 26th April, 1939, forenoon.

Lieutenant-Colonel R. H. Candy, C.I.E., whose services were placed at the disposal of the Government of Burma from 21st April, 1939, assumed charge of the duties of Inspector-General of Civil Hospitals, Burma, *vice* Lieutenant-Colonel A. Ba Thaw, on the forenoon of the 26th April, 1939.

Lieutenant-Colonel J. M. Mitchell, O.B.E., to be Officiating A. D. M. S., Kohat District. Dated 21st April, 1939.

Lieutenant-Colonel B. S. Dhondy to be O. C., I. M. H., Lucknow. Dated 14th April, 1939.

Lieutenant-Colonel H. S. G. Haji, M.C., to be Officiating O. C., I. M. H., Secunderabad. Dated 1st April, 1939.

Lieutenant-Colonel F. Phelan to be O. C., I. M. H., Poona. Dated 14th April, 1939.

Lieutenant-Colonel J. W. F. Albuquerque to be O. C., I. M. H., Thal. Dated 17th April, 1939.

Lieutenant-Colonel N. S. Jatar, C.I.E., D.S.O., Inspector-General of Prisons, C. P. and Berar, has been appointed to officiate as Inspector-General of Civil Hospitals, C. P. and Berar, in addition to his own duties from 24th April, 1939.

The Governor is pleased to appoint Lieutenant-Colonel K. S. Thakur, now on leave *ex-India*, to act as Surgeon-General with the Government of Bengal in the leave vacancy of Major-General Mills, with effect from the date on which he takes over charge from Lieutenant-Colonel T. C. Boyd, now officiating as Surgeon-General.

Lieutenant-Colonel H. E. Murray, Surgeon Superintendent, Presidency General Hospital, Calcutta, on relief, is appointed to act as Professor of Midwifery, Medical College, Calcutta, *vice* Lieutenant-Colonel P. F. Gow, or until further orders.

The services of Lieutenant-Colonel B. P. Baliga, Superintendent, Dum Dum Central Jail, are replaced at the disposal of the Government of India, Defence Department, with effect from the 20th June, 1939, or any subsequent date on which he may be relieved.

Major F. H. Whyte is appointed to the post of Civil Surgeon, Simla West, with effect from the forenoon of the 21st April, 1939.

Major B. D. Khurana to be D. A. D. H., Rawalpindi District. Dated 2nd March, 1939.

Major C. Mani to be Officiating D. A. D. H., Bombay District. Dated 13th March, 1939.

Major A. Tait to be O. C., C. I. M. H., Manzai. Dated 10th March, 1939.

Major T. A. Malone to be O. C., I. M. H., Aurangabad. Dated 13th March, 1939.

Major T. B. Pahlajani to be Officiating D. A. D. M. S., Waziristan District. Dated 6th February, 1939.

Major M. H. Wace to be O. C., Labour Camp Hospital, Quetta. Dated 17th March, 1939.

Major M. H. Shah, Additional Civil Surgeon, Delhi, is appointed temporarily to officiate as Chief Medical Officer, Delhi, with effect from the date he assumes charge of the duties, *vice* Lieutenant-Colonel R. H. Candy, C.I.E., transferred to Burma.

Major J. H. Gorman was attached to the Port Health Department, Calcutta, from the 10th to the 20th March, 1939, and is appointed to officiate as Port Health Officer, Calcutta, from the 21st March, 1939, until further orders.

On transfer from Campbellpur, Major B. Temple-Raston assumed charge of the Office of Civil Surgeon, Murree, on the forenoon of the 18th April, 1939.

Major G. Milne, an Officiating Agency Surgeon, is posted as Residency Surgeon, Kashmir, with effect from the afternoon of the 1st April, 1939.

Major C. Mani to be D. A. D. H., Bombay District. Dated 22nd April, 1939.

Major D. N. Chakravarti to be O. C., I. M. H., Allahabad. Dated 6th April, 1939.

Major C. A. Bozman, Director of Public Health, Burma, made over and Major T. J. Davidson received charge of the duties of the Director of Public Health, Burma, on the afternoon of the 20th April, 1939.

Major H. S. Waters has been appointed as Civil Surgeon and Superintendent, B. J. Medical School, Poona, with attached duties, with effect from the forenoon of 11th April, 1939, *vice* Lieutenant-Colonel F. R. Thornton, M.C., proceeded on leave.

Major G. B. W. Fisher made over charge of the Barisal Jail to Dr. G. De in the forenoon of the 1st April, 1939.

Major J. C. Drummond, Civil Surgeon, Darjeeling, is appointed to act as Surgeon Superintendent of the Presidency General Hospital, Calcutta, *vice* Lieutenant-Colonel H. E. Murray.

Major K. S. Fitch, Civil Surgeon, Burdwan, on relief, is posted to Darjeeling as Civil Surgeon, *vice* Major J. C. Drummond.

Captain T. F. O'Donnell was transferred to Civil employ in the United Provinces from 6th April, 1939.

Captain A. T. Andreasen was transferred to Civil employment in the United Provinces from the 14th April, 1939.

Captain F. C. Leach, Superintendent, Mental Hospital, Nagpur, has been appointed as Civil Surgeon and Superintendent, Robertson Medical School, Nagpur, in addition to his own duties from 11th April, 1939.

Captain J. H. Bowie to be Officer-in-Charge, Brigade Laboratory, Dehra Dun. Dated 6th April, 1939.

Captain W. A. Hopkins to be Specialist in Ear, Nose and Throat, Western Independent District. Dated 19th April, 1939.

Captain F. H. A. K. Davidson made over charge of the Jalpaiguri Jail to Babu Ajit Kumar Gupta in the afternoon of 28th February, 1939.

Captain G. C. Retz to be Officiating Officer-in-Charge, I. H. C. Records, Kirkee. Dated 25th March, 1939.

Captain R. C. Dracup to be Officer-in-Charge, Brigade Laboratory, Allahabad. Dated 20th March, 1939.

Captain A. A. Pullar has been appointed as Presidency Surgeon, Bombay, with attached duties, with effect from the forenoon of 3rd April, 1939, vice Major H. S. Waters, transferred.

Captain H. W. G. Staunton is appointed to officiate as an Agency Surgeon, with effect from the forenoon of the 1st April, 1939, and is posted as Agency Surgeon, Bundhelkand, with effect from the same date.

The undermentioned officers arrived Bombay on 14th February, 1939, per S. S. *Castalia* on first appointment:—

Lieutenant H. V. Morris.

Lieutenant L. D. B. Frost.

Lieutenant A. M. Mackenzie.

Lieutenant R. M. McCullough.

Lieutenant F. W. Snedden.

Lieutenant E. J. Somerset.

Lieutenant J. L. M. Whitbread.

Lieutenant A. N. Roy reported at I. M. H., Rawalpindi, on 20th March, 1939, for preliminary training, on being granted a short service commission in the Indian Medical Service.

LEAVE

The Governor is pleased to grant leave for 6 months to Major-General P. S. Mills, C.I.E., Surgeon-General with the Government of Bengal, with effect from the 24th March, 1939.

Colonel A. C. Munro, A. D. M. S., Western Independent District, proceeded on 5 months' combined leave *ex-India* from 3rd April, 1939.

Colonel W. L. Watson, O.B.E., A. D. M. S., Kohat District, proceeded on 2 months' privilege leave *ex-India*, pending retirement, from 21st April, 1939.

Colonel D. H. Rai, M.C., Inspector-General of Civil Hospitals, Central Provinces and Berar, is granted 4 months' leave from 24th April, 1939.

The previous notification regarding the grant of leave to Lieutenant-Colonel R. H. Candy, C.I.E., and the appointment of Major M. H. Shah to officiate for him are hereby cancelled.

Lieutenant-Colonel A. C. Macrae, O. C., C. I. M. H., Dehra Dun, proceeded on 8 months' combined leave *ex-India* from 17th March, 1939.

Lieutenant-Colonel R. F. D. MacGregor, M.C., an Agency Surgeon, is granted leave on average pay for 15 days combined with leave on half-average pay for 8 months and 22 days, with effect from the forenoon of the 29th March, 1939, pending retirement.

Lieutenant-Colonel R. H. Malone, Pathologist, Rangoon General Hospital, was granted leave for a total period of 6 months from 1st April, 1939.

Lieutenant-Colonel F. R. Thornton, M.C., has proceeded on leave on average pay for 3 months and 17 days from 11th April, 1939, to 27th July, 1939, followed by leave on half-average pay for 8 days from 28th July, 1939, to 4th August, 1939, preparatory to retirement from 5th August, 1939. He was permitted to prefix the Easter Holidays commencing on 7th April, 1939, to the leave.

Lieutenant-Colonel M. L. Treston, Medical Superintendent, Rangoon Dufferin Hospital, was granted leave on average pay for 2 months from the 7th April, 1939.

Lieutenant-Colonel R. Lee, O. C., I. M. H., Jubbulpore, proceeded on 8 months' combined leave *ex-India* from 17th April, 1939.

Lieutenant-Colonel N. K. Bal, District Medical Officer and Superintendent, District Headquarters Hospital, Trichinopoly, leave for 1 month and 14 days, with effect from 1st May, 1939, or date of relief whichever is later.

Lieutenant-Colonel M. M. Cruickshank, Senior Specialist in Surgery, Superintendent and Surgeon, Government General Hospital and Professor of Surgery, Medical College, Madras, leave out of India for a period of 4 months and 23 days, with effect from 8th May, 1939, or date of relief.

Lieutenant-Colonel P. F. Gow, Professor of Midwifery, Medical College, Calcutta, is granted leave for 3 months, with effect from the 10th May, 1939, or from any subsequent date on which he is relieved.

Major K. F. Alford, D. A. D. II., Bombay District, proceeded on 7½ months' combined leave in and *ex-India* from 13th March, 1939.

Major K. H. A. Gross, M.C., an Officiating Agency Surgeon, is granted leave for 2 months and 14 days, combined with furlough for 9 months and 16 days, under the military leave rules, with effect from the forenoon of the 1st April, 1939.

Major F. R. W. K. Allen, Civil Surgeon and Superintendent, Robertson Medical School, Nagpur, is granted 2 months and 20 days' leave from 11th April, 1939.

Major C. Bozman, Director of Public Health, Burma, was granted leave on average pay for 8 months from the 21st April, 1939.

Major B. Chandhuri, Senior Medical Officer, Port Blair, is granted leave on average pay up to 31st July, 1939 (inclusive), with effect from the date he is relieved of his duties, and his services are placed at the disposal of the Government of Bengal, with effect from 1st August, 1939, for employment in the Bengal Jail Department.

PROMOTION

Lieutenant-Colonels to be Colonels

H. J. M. Curseljee, D.S.O. Dated 1st December, 1938, with seniority from 1st January, 1934.

J. S. S. Martin. Dated 17th December, 1938, with seniority from 27th July, 1934.

Majors to be Lieutenant-Colonels

R. K. Tandon. Dated 15th March, 1939.

H. M. Strickland. Dated 22nd March, 1939.

The seniority of Captain A. H. Barzilay has been antedated as follows:—

Lieutenant. Dated 18th August, 1930.

Captain. Dated 18th August, 1933.

Lieutenants (on probation) to Captains (on probation)

M. D. Black. Dated 10th January, 1939, with seniority from 1st March, 1938.

G. J. H. Maud. Dated 10th January, 1939, with seniority from 1st March, 1938.

I. D. Sutherland. Dated 10th January, 1939, with seniority from 1st March, 1938.

J. J. Woodward. Dated 10th January, 1939, with seniority from 1st September, 1933.

S. H. Heard. Dated 10th January, 1939, with seniority from 1st September, 1938.

J. E. Ennis. Dated 10th January, 1939, with seniority from 1st September, 1938.

H. R. Loughran. Dated 10th January, 1939, with seniority from 17th October, 1938.

D. J. P. Spillane. Dated 18th April, 1939, with seniority from 18th January, 1939.

P. M. Kirkwood. Dated 12th February, 1939, with seniority from 12th February, 1939.

RETIREMENTS

Lieutenant-Colonel E. A. Penny, 5th March, 1939.

Lieutenant-Colonel R. E. Flowerdew, C.I.E., 16th April, 1939.

Lieutenant-Colonel L. S. Modi, 3rd May, 1939.

RELINQUISHMENTS

Major R. McRobert, Civil Surgeon, Prome, on transfer, relinquished charge of the duties of Civil Surgeon, on the forenoon of 1st April, 1939.

Major T. J. Davidson relinquished charge of the duties of the Civil Surgeon, Moulmein, on the afternoon of the 17th April, 1939.

Notes

ALBUCID

MESSRS. SCHERING (INDIA), LIMITED, have introduced into India the above sulphonamide preparation, which has been found, after extensive experiments, to be particularly useful in gonorrhoea (all stages, its complications as well) and in *B. coli* and staphylococcal infections. Their research work has been conducted on the lines of the fate of sulphonamide in the human body. Pharmacological research on sulphonamide has shown that it is partly detoxicated by the organism through acetylation and excreted as acetyl-amino-sulphonamide. This intermediate detoxicated derivative proved inactive in chemotherapeutic trials. They, therefore, prepared a product of the same empirical formula as that occurring in the body, but in which the detoxicating acetyl radicle was firmly fixed in another position in the molecule, i.e., in the amino group of the sulphonic acid chain. This new, hitherto unknown, combination is 4 amino-benzene sulphonacetamide and is called Albucid. According to expectations, chemotherapeutic experiments have shown that not only is Albucid excellently tolerated, but it also displays a very high therapeutic effect. Only 7 days' treatment is necessary in gonorrhoea, with 2 to 3 daily irrigations of potassium permanganate as a hygienic measure, but no previous sensitization with a gonococcal vaccine is necessary. In staphylococcal and *B. coli* infections, 8 days' treatment with a dosage of 2 tablets, 3 times a day, renders the urine sterile.

BRITISH COD-LIVER OIL PRODUCERS
(HULL) LIMITED

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—Recently in the Indian Press, there have appeared various articles drawing attention to the many malpractices which exist in the cod-liver oil trade of India. Articles have appeared on the findings of scientific workers which proved that much of the cod-liver oil used in India was adulterated or of inferior quality.

In view of the publicity which this state of affairs is now receiving, we wish to inform your readers that any cod-liver oil they may purchase which is manufactured by this Company is guaranteed pure cod-liver oil of the finest quality, rich in vitamins and quite free from the disagreeable taste of cod-liver oil produced by inferior methods.

Yours, etc.,

BRITISH COD-LIVER OIL PRODUCERS
(HULL) LIMITED

ST. ANDREW'S DOCK,
HULL,
28th March, 1939.

'BACK TO ACTIVITY'

THIS is a small book composed principally of illustrations of actual cases showing the good cosmetic and

mechanical results obtained with Desoutter artificial limbs.

CALCIUM-DIURETIN-KNOLL

CALCIUM-DIURETIN, prepared by the Knoll Chemical Works, has an ever-constant content of 48 per cent theobromine and 11 per cent calcium. The chemically bound calcium component supports and advantageously complements the theobromine and salicylic acid action. Apart from its favourable influence on the circulation, calcium acts as a synergist of theobromine in respect of the latter's vascular and diuretic influence. The advantage of diuretin treatment thus assisted by calcium substitution therapy finds its proof in the increased elimination of salt. Tolerance leaves nothing to be desired owing to the antiphlogistic protection of the gastric mucous membrane by the calcium component and the fact that Calcium-Diuretin passes through the stomach largely unchanged and is thus dissolved in, and absorbed from, the intestine. The chemical union of calcium and diuretin deprives the latter of its alkaline taste which renders administration uniformly easy. Calcium-Diuretin is extensively used for the promotion of diuresis and the heart action and to quiet vascular spasms. Its excellent tolerability is of particular value for cases requiring the prolonged use of a theobromine preparation.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

A NOTE ON SOME CASES OF LATHYRISM IN A PUNJAB VILLAGE

By S. R. A. SHAH, K.S., M.A., B.S. (Punjab),

B.T.M. (L'pool), D.P.H. (Lond.)

District Medical Officer of Health, Sialkot

Introduction

IN October 1935, I received information that in the village of Nawan Kulla in Narowal *tehsil* the inhabitants had been stricken with a mysterious malady which had crippled them. The villagers attributed this to the curse of certain Sadhus who had been abused and turned away from the village by them. Suspicious of an outbreak of an unusual disease like infantile paralysis or scurvy, I left for the village. Soon after my arrival I was surrounded by a crowd of villagers many of whom had walked up to me with difficulty with a waddling gait and supported by long sticks. This type of disease is not known to have occurred in this part of the province before.

Circumstances of village Nawan Kulla

The village is situated some eight miles to the south-west of Narowal town and about two miles from Raya station on the North Western Railway. The Punjabi word *nawan* means new. It is so called because the village is of recent origin, about 15 years old, and is really an off-shoot of the older and bigger village Kulla from which it is separated by about a mile. Originally it was just a well with one or two huts close by. Certain poor families from Kulla gradually migrated to this place and thus a small village sprang up.

Nawan Kulla is situated in a low-lying area. Drainage of the high ground to the north and east of the village runs along the southern boundary of the village to join the Ravi river which is four miles from it. When the monsoon rains have been heavy the village gets surrounded by water on three sides.

The population of the village is 205, out of which 104 are Sikhs, 71 Muslims, 21 Christians and 9 Hindus. The 9 Hindus belong to one family of 'Kahars' who are engaged as water carriers. Out of the 9 families of Muslims, 5 are weavers, 3 carpenters and one potters.

The Sikhs are agriculturists. Their holdings are very small and they are extremely poor. The land is irrigated from wells, and where these do not exist they depend on rainfall for their cultivation. The soil is poor in quality. The chief 'Kharif' crops are rice and maize and 'Rabi' crops are wheat and a certain amount of pulses. A small amount of ghee and a little superfluous grain are exported and these constitute the only outside source of income. The Muslims are somewhat better off economically,

but the poverty of the village as a whole can be well judged from the fact that there is not a single *bania's* shop in the village.

As regards diet, the Muslims eat well and an occasional plate of meat or eggs provides some variety in the routine diet of wheat *roti* with *dāl*, whey or *sag*. The Christians also, on account of the nature of their avocation (labour), get some change in their food as they move from place to place in search of work. The Sikhs, being poor and more or less stationary in the village, sustain themselves on the monotonous diet of wheat *roti* taken with *dāl*, *sag*, boiled turnips or pickle. Rice is taken occasionally.

Clinical manifestations of the disease.—Enquiry elicited that the disease had made its appearance in the month of June and since then had steadily increased. At the time of enquiry 64 persons out of a population of 205 were seen in the various stages of the disease.

Onset.—In 34 cases premonitory symptoms such as attacks of nausea or vomiting after meals and diarrhoea manifested themselves for 5 to 14 days before the characteristic symptoms of the disease appeared. Two of these cases also gave a history of attacks of intermittent fever with rigors and sweating lasting for 5 or 6 days. In the remaining 30 cases the disease was reported to have come on suddenly, and often during the night. Persons who had gone to bed quite well awoke next morning feeling stiff in the legs.

A marked feature in a number of cases was the sensory symptoms in the affected limbs, which preceded or accompanied the paralytic symptoms. A tingling sensation appeared in the soles of the feet which soon spread to the legs. Analgesia, anaesthesia and formication were also present. Both legs were affected simultaneously.

Thus, it will be seen that the earliest symptoms varied from gastro-intestinal disturbances to sensory symptoms in the legs or spasticity of the legs.

General symptoms.—Within 10 days to a month of the onset, signs and symptoms of a spastic diplegia supervened. The influence of muscular tension was apparent in the gait of the patients. Early and slight cases were able to walk for a fairly long time but the movements of the legs were slow and laboured. The knees got slightly bent owing to over-action of the flexors and more weight was thrown on the toes than on the heels. For a month or so the spastic symptoms predominated over the parietic, the spastic gait then gradually changed to spastic-parietic, and a decrease in muscular power was complained of in addition to the stiffness. Paresis of the leg muscles varied from simple impairment of movement to more or less complete paralysis of the muscles of the legs. The flexor muscles were involved first as a rule. The patient could not, or only with difficulty, dorsiflex the foot. The muscles of the affected limbs

were hypertonic. Any attempt at movement, active or passive, gave rise to muscular contraction which sometimes was painful.

The superficial reflexes, epigastric and abdominal, were exaggerated in the early cases but were feeble or altogether absent in the old cases. The plantar reflex, so difficult to elicit in the horny soles of the villagers, was extensor in type in those in whom it could be elicited (Babinski's sign). Knee jerks were also exaggerated in all early cases, but tended to get sluggish as the disease advanced. Ankle clonus was elicited in 14 cases. The sphincters of the rectum and bladder were unaffected. There was no impairment of the functions of the cranial nerves and speech, sight and hearing were normal. There were no mental symptoms or psychic disturbances. Sexual potency was diminished in some but never lost. Bed sores were not seen.

The respiratory and circulatory systems showed no involvement. Urine analysis and microscopic examination of blood revealed nothing of interest. Wassermann reaction in the case of three patients who were sent to Mayo Hospital, Lahore, proved negative.

Notes on some cases

The following are brief notes on some cases :—

Case I.—(Fig. 1.) A Sikh female, aged 19 years. She was one of the earliest who developed the disease and was a bad case. The disease started with an acute tingling sensation in the soles of the feet which soon spread to the legs. Walking was troublesome on account of hyperaesthesia and analgesia of the soles of the feet. In a few days spastic symptoms developed in the legs which made walking still more difficult. Adduction of the thighs and flexion of the legs became so firm that any passive or active effort at straightening or separating the legs was accompanied by extreme pain. Weakness of the legs also appeared and gradually increased. At this stage tingling sensation appeared in the palms of hands also, but it was not as marked as that of the soles of the feet. Spasticity and paresis of the forearms also developed but to a much lesser extent than in the legs. Hyperkeratosis of the soles of the feet became evident a couple of months after the onset. Some hyperkeratosis of the palms of the hands was also evident later on.

Fig. 1.

Present condition.—Her gait is still spastic but she is able to do all her household work. The knee jerks are slightly exaggerated. There is no permanent shortening of any muscles.

Case II.—(Fig. 2.) A Sikh, aged 30 years. He was one of the earliest cases, and his condition was definitely the worst. The disease was ushered in by dyspepsia and vomiting on taking wheat chapatis. This was followed by the usual symptoms of the disease. The special feature was the acute involvement of the upper extremities which gave rise to wrist drop and 'main en griffe' which is well illustrated in the photograph.

Fig. 2.

Present condition.—The spasticity and weakness of the muscles is still considerable. He can manage to walk with the help of a stick, but with laboured steps. In spite of serious and prolonged illness there are hardly any trophic changes.

Sex distribution.—Out of 115 males and 90 females residing in the village, there were 38 males and 26 females affected with lathyrism, i.e., about 33 per cent of the male population and 28 per cent of the female population suffered.

Age distribution.—Out of the 64 cases that occurred, the following was the incidence rate per 100 by decennial age groups.

Age group	Population	Number of cases	Percentage affected
1-10 years ..	36	9	25
11-20 " ..	61	18	30
21-30 " ..	59	24	41
31-40 " ..	37	9	24
41-50 " ..	13	4	30

Racial distribution

Community	Population	NUMBER OF PERSONS AFFECTED		
		Total	Males	Females
Sikhs ..	104	59	35	24
Muslims ..	71	5	3	2
Christians ..	21
Hindus ..	9
TOTAL ..	205	64	38	26

It will be seen from the above table that the members of the Sikh community were the principal sufferers. Fifty-nine cases out of 64

occurred amongst them, and all advanced cases were Sikhs. The 5 cases that occurred amongst the Muslims were of a mild type.

Seasonal occurrence.—The distribution of cases according to the month of onset is given below :—

June	8
July	16
August	21
September	14
October	5

The disease started in June, was in full swing in July, August and September, and in October its progress was arrested with the institution of preventive and curative measures detailed elsewhere.

Diagnosis

The mode of onset and course of the disease, spastic paraplegia, characteristic gait, and improvement of cases on giving up the use of suspected articles of diet, led one to the conclusion that the disease was lathyrism. This diagnosis was later confirmed by Dr. A. B. Arora, Assistant Director of Public Health, Lahore.

Differential diagnosis

Beri-beri.—The disease resembles beri-beri (dry form) in certain respects and is likely to be mistaken for it. In fact, the multiple peripheral neuritis and the dyspeptic symptoms seen in some cases suggested beri-beri in the first instance, but on closer examination of aetiological factors and clinical manifestations important differences were noticed. Namely, the patients did not live chiefly on rice and did not use white wheaten flour, the muscles were not found wasted and flabby, and the typical cardiac symptoms were absent.

Ergotism (spasmodic type) is differentiated by the facts that rye is not used at all in this area, and vertigo, headache and epileptiform convulsions were absent. To make certain that cereals other than rye had not been attacked by the fungus *Claviceps purpurea* the flours derived from wheat and rice were tested for ergot by the simple test advocated by Bottger; viz, the sample is mixed with ether and a few crystals of oxalic acid added. It is then brought to the boil and allowed to become clear by standing. If the clear supernatant fluid shows a red tinge ergot is present.

Pellagra.—The characteristic skin eruption, sore mouth and the psychic disturbances in pellagra were absent.

Ætiology

The elucidation of the causal factor presented a certain amount of difficulty. *Lathyrus sativus*

(*matlar* or *khassari*), which is most commonly associated with the disease, is not grown or used in this area. The cereals grown and used by the villagers are :—wheat, maize, gram, *urad*, *mung* and rice.

Maize, *urad*, *mung* and rice are eaten sparingly and very small quantities of these were recovered from the houses. On my first visit to the village, the villagers were advised to give up the use of all old stocks of food grains and obtain fresh supplies from a distant village. They got rid of the old stocks by feeding cattle on them or giving them to me for purposes of examination, with the exception of wheat, of which they had considerable quantities and were loath to part with and I did not press them at that time because I did not suspect wheat to be the cause of the mischief. Samples of wheat, however, along with those of other cereals were sent to the public health chemist for examination in collaboration with the Professor of Botany of the Government College, Lahore. In the meantime I was struck with a general complaint of the patients that whenever they ate wheat *chappatis* there was a set-back in their progress. The spasticity of the legs increased and they felt worse next morning. At first I took this to be just an accident but later when they persisted in their complaint I instituted a detailed enquiry. It was elicited that this complaint came only from those who had old stocks of wheat, while those who were not using wheat, or had obtained fresh stocks of wheat, did not suffer from such exacerbations of the symptoms. It was discovered that some of the villagers had not actually disposed of their old stocks of *dāl* and rice, and were still making use of them. These also said that when they partook of *dāl* and rice they did them no harm, but when *chappatis* made from old wheat were taken it made them feel worse. This focussed my attention on the wheat. The old stocks of wheat were found to be contaminated with seeds of *Vicia sativa* (*akta*) to a considerable extent. A handful of wheat when placed on a dish showed eight or ten seeds of *akta* at a glance. The report of the public health chemist confirmed this, and he reported that wheat flour was contaminated with *akta* as well. As a further test that the seeds contaminating the wheat were of *Vicia sativa* and nothing else, the seeds were sown and grown up plants compared with the dried specimen of *Vicia sativa* plant kindly given to me by the Professor of Botany, Government College, Lahore. The use of old wheat was discontinued and the complaint of set-backs ceased with it.

In view of the observations made and explained above I am of the opinion that seeds of *Vicia sativa* contaminating the wheat were the root cause of lathyrism in this outbreak. The fact that the incidence of the disease coincided with harvesting the wheat crop lends support to this view.

Treatment

Proper dietetic and medicinal treatment could not be carried out on account of the extreme poverty of the sufferers whose meagre resources had been further depleted by the long illness of the earning members, and also by their payments to quacks, *hakims* and *vaids* in the hope of getting cured during the four months prior to my visit. At my request the Sialkot District Board very considerably sanctioned Rs. 200 for the treatment of the cases. Another Rs. 20 were collected by contribution. This enabled me to provide rations of milk, eggs and vegetables for the cases (one family had to be given even wheat to save the members from starvation), and also to institute medicinal treatment. Mild cases were put on iron-arsenic mixture while advanced cases were given an iodide mixture. A digestive tonic mixture was also given when symptoms demanded it. With alteration in diet, the disease was arrested but the improvement of cases was very slow. Medicinal treatment failed to produce any marked effect. After a month's trial of this routine, intensive vitamin treatment was added to it. Half the cases were put on Adexolin and the other half on halibut oil. Under the vitamin treatment there was a marked acceleration in the rate of progress of the cases. Full doses of halibut oil and Adexolin were administered regularly. On account of the high cost of these preparations their administration had to be restricted to bad cases only, and when improvement reached a certain stage these had to be stopped. Under this treatment the aching of spastic muscles and tingling sensation in the feet, when present, were the first to disappear. The spasticity diminished and the muscles gradually acquired strength. The treatment was kept up for six months. At the end of that period more than half the cases had returned to their respective avocations while the remainder had progressed remarkably. Only a few milder cases, however, could be considered cured completely as quite a number still complained of stiffness of the legs.

Discussion

Some uncommon features were observed in this outbreak which are worth mentioning.

McCombie Young (1927) found malarial fever a common antecedent of lathyrism. The village Nawar Kulla is not situated in a malarious tract, no one was found to possess a palpable spleen and only 2 cases out of 64 gave history of intermittent fever preceding the attack.

Sensory disturbances which formed quite a marked feature of this outbreak have generally not been noticed. Marked anaesthesia and analgesia are described by Proust (Stockman, 1917), but not by other authors.

The sphincters are usually described as affected but they were not affected at all in this series of cases. Sexual potency, which is often

(Continued at foot of next column)

THE USE OF BLOOD TESTS IN EXCLUDING PATERNITY AND MATERNITY

By S. D. S. GREVAL

LIEUTENANT-COLONEL, I.M.S.

Imperial Serologist and Chemical Examiner to the Government of India

Imperial Serologist's Laboratory, The School of Tropical Medicine, Calcutta

I. Definitions and explanations of terms

By the term 'blood test' in connection with excluding paternity or maternity is meant the determination of the blood groups and the blood types of the subjects concerned.

The blood groups are four : O, A, B and AB. The types within each group are : M, N and MN. The accompanying diagram explains these and

(Continued from previous column)

reported as lost (Stockman, 1917), was reduced but never altogether lost.

The legs only are usually reported to be affected (Sleeman, 1844). In this outbreak the arms were involved in a number of cases.

Sex incidence is generally reported by authors as 5 to 10 times greater in the males than in the females. In this outbreak it was 3 males to 2 females who suffered.

Lathyrism being absolutely unknown before in this part of the country it is rather difficult to arrive at much aetiological and epidemiological data from observations made in one outbreak. Taking everything into consideration it seems probable that this outbreak was due to the presence of seeds of *Vicia sativa* in wheat. It thus lends support to the *akta* contamination theory first advanced by Anderson *et al.* (1925). The legume *Lathyrus sativus* is neither grown nor used in this area to any extent and is, therefore, out of the question.

Avitaminosis seems to play some part in the production of symptoms. In support of this it may be stated that many symptoms resemble beri-beri and pellagra, two known 'deficiency' diseases, and that the cases improved remarkably under dietetic and vitamin treatment.

Judging from the symptoms it seems probable that the pyramidal tracts of the spinal cord are chiefly involved, although variations in symptoms suggest that more than one tract is affected. It is also probable that the peripheral nerves, both motor and sensory, are involved.

New
O
A
B
AB

A and B are the iso-hæmagglutinogens.

a and b are the corresponding iso-hæmagglutinins.

The group is named after the iso-hæmagglutinogens.

The four groups indicate the only four possibilities, compatible with life, in which the iso-hæmagglutinogens and the iso-hæmagglutinins can co-exist in the same subject. In a 'defective' group an iso-hæmagglutinin which can exist compatibly with life is absent (e.g., O, a; A, o).

Further division of A into A₁ and A₂ (and into A₁B and A₂B) increases the number of groups to six.

Quite unrelated to A and B are the hæmagglutinins (not iso-hæmagglutinogens) M and N. They occur as M, N, or MN in all subjects of all groups. No subject is free from them. They differentiate three types in each group and thus make possible 12 descriptions of blood, if only the original four groups are considered, or 18 descriptions, if sub-groups with A₁ and A₂ are also considered. A blood may be:—

OM	ON	OMN
AM	AN	AMN
BM	BN	BMN
ABM	ABN	ABMN

There are difficulties of technique in determining A₁ and A₂. They are, therefore, ignored by many workers in forensic medicine. M and N are easily determinable and are receiving due recognition all over Europe and America.

II. Legal position

The legal opinion in England concerning the reliability of the groups in determining paternity (or maternity) was given to me in a nutshell by a veteran worker in biology at an ancient seat of learning and also a J.P., in January 1938,

on the occasion of the combined session of the All-India Science Congress Association and the British Association for the Advancement of Science, in Calcutta. The scientist J.P. had been advised by a whole-time magistrate thus: 'When evidence dealing with blood groups is adduced, listen attentively, take notes and ask questions; otherwise the party adducing the evidence will say in the higher court that the presiding judicial authority did not follow the evidence; having done as advised forget all about it'. This was at least the conservative opinion and as such was respected by all admirers of good old conservative institutions.

During the same year things appear to have moved very fast indeed. A case decided on the evidence of blood groups and blood types was published in the *British Medical Journal* of 21st May, 1938.

In America and Germany blood groups were pressed into service of the law many years ago. Lately blood types have done even more service. Cases which were decided on the evidence of the groups some time ago have been re-opened for the evidence of the types.

The writer has tested for medico-legal purposes only a few parties consisting of several members. His opinion, however, has been given to a party's legal advisers and medical officers of certain Indian States. He has not yet sent a report to a court of law. Many enquiries have been answered. The number of the enquiries is increasing and is responsible for this communication.

III. Possible and impossible parents and offspring

In this communication it is not intended to go into the details of the serological technique of grouping and typing blood. Nor is a discussion on biological subtleties and genetics intended. Suffice it to say that the blood groups of the parents are known to be inherited by the offspring in a certain way only. The same is true of the blood types. The appended tables give the inheritance of the blood groups and the blood types.

Table I can be summarized in two laws:—

1. The iso-hæmagglutinogens A and B cannot appear in the blood of a child unless present in the blood of one or both parents.

2. A group AB parent cannot have a group O child and a group O parent cannot have a group AB child (aid to memory—universal donors and universal recipients cannot be parents and offspring to each other).

The genetic basis is triple aldomorphism. The contrasting characters are O, A and B. O is recessive while A and B are dominant.

Table II also can be summarized in two laws:—

1. The agglutinogens M and N cannot appear in the blood of a child unless present in the blood of one or both parents.

: 2. A type M parent cannot have a type N child and a type N parent cannot have a type M child.

The genetic basis is the fact that both M and N are dominant. The genotypes of the phenotypes M, MN and N are MM, MN and NN.

It will be observed that the second law, both in the case of the groups and the types, makes it possible to exclude an offspring after examining one parent only. An AB parent cannot have an O offspring no matter what the blood group of the other parent is. Nor can an O parent have an AB offspring no matter what the blood group of the other parent is. Similarly a type M parent cannot have a type N offspring no matter what the type of the other parent is. Nor can a type N parent have a type M offspring no matter what the type of the other parent is.

It will also be observed that two A parents, two B parents, and A and B parents can have O offspring.

The determination of the group and the type can only *exclude* an offspring or a parent. It can only prove that Mr. Smith is *not* the father of Master Tom. It cannot prove that Mr. Brown is the father of Master Tom. As affirmative evidence the most it can indicate is that Mr. Brown *can be* the father of Master Tom. The same remarks apply to Mrs. Smith and Mrs. Brown regarding motherhood.

IV. Arranging for performance of the blood tests

Test number one. Determination of blood groups.

Any medical man in charge of a bacteriological laboratory and interested in serology will be able to determine the groups of the child and of the putative parents. Every province in India has at least one such laboratory. Most military laboratories also keep the testing sera. The party to be tested simply walks into the laboratory and the serologist does the rest. A few c.cm. of blood are taken from a vein. The red blood cells of the subjects are tested with known sera and the sera of the subjects are tested with known cells. The result is ready in about an hour. Giving of the blood is not very painful.

If the party decides to send the blood to the laboratory of the Imperial Serologist the following specimens are needed:—

(1) About 0.25 c.cm. of blood dried on a chemically-pure filter paper. The blood is dried quickly but not in the sun. An unstained part of the filter paper should also be available.

(2) About 0.5 c.cm. of clear serum. This is taken from a test-tube in which blood (about 3 c.cm.) has been allowed to clot, *under sterile condition*, without disturbing the contents much.

(3) About 0.5 c.cm. of serum turbid with red blood cells. This is taken after shaking the contents of the tube, after the clear serum has been removed.

The specimens are taken by a responsible medical man, preferably an official, and sent in a sealed and registered parcel. The impression of the seal is sent in another sealed and registered parcel.

The stain on the filter paper is tested for the iso-agglutino-gen by absorption. The clear serum is tested for the iso-agglutinins against known red blood cell suspensions.

If all has been well with the sterile precautions the turbid serum will yield, on centrifuging, red blood cells in a good state of preservation. They are made into a 2 per cent suspension and examined for auto-agglutination. If found satisfactory, they are tested against known sera.

The writer considers results obtained from stains satisfactory and those from serum confirmatory. The direct testing of the red blood cells obtained from the turbid serum is also confirmatory. It will not replace the absorption test; old red blood cells are not to be considered reliable in hæmagglutination for medico-legal purposes.

Opinion is withheld if a 'defective' group complicates an incompatible combination. Fresh blood will be required for repeating the tests.

The determination of the group may exclude paternity or maternity (*vide* table I). If it does not, determination of the type must be undertaken.

Test number two. Determination of blood types.

This test is undertaken in India, at present, in the writer's laboratory only. Fresh blood is necessary.

TABLE I
Blood groups in parents and children

	Parents	Children possible	Children impossible
1	O × O	O	A, B, AB
2	O × A	O, A	B, AB
3	O × B	O, B	A, AB
4	A × A	O, A	B, AB
5	A × B	O, A, B, AB	
6	B × B	O, B	A, AB
7	O × AB	A, B	O, AB
8	A × AB	A, B, AB	O
9	B × AB	A, B, AB	O
10	AB × AB	A, B, AB	O

THE USE OF DYES IN VARIOUS FUNGAL INFECTIONS

By P. A. MAPLESTONE, D.S.O., D.Sc., M.B., D.S., D.T.M.

and

N. C. DEY, M.B. (Cal.)

(From the Medical Mycology Inquiry, Indian Research Fund Association, at the School of Tropical Medicine, Calcutta)

GENTIAN VIOLET has been used in dermatology for a long time. As early as 1900 Hyde and Montgomery in their treatise on skin diseases mention the efficacy of gentian violet as a local application in various skin conditions. The first laboratory investigation on the action of gentian violet dates from the work of Churchman (1912) who observed the marked selective action of this dye *in vitro* on Gram-positive organisms. He proved its practical value (1920) when applied to wounds and ulcers. Since then gentian violet has been widely used in different staphylococcal infections. Sauphar (1923) and Sutton (1938) recommended its use locally in 'pemphigus neonatorum'; Smith and Casparis (1923) and Young and Hill (1924) used it intravenously in staphylococcal septicæmia; MacKenna advocated it in multiple boils in children (1937).

Gentian violet and other aniline dyes were tested *in vitro* against ringworm fungi by Schamberg and Kolmer (1922), and Kingery and Adkisson (1928). The fungicidal and fungistatic properties of some of these dyes were found to be powerful. These dyes have also been

tested *in vitro* against monilia by Clark (1927), Iain and Kurotchkin (1930), Hesselstine and Hopkins (1935), Gomez-Vega (1935) and clinically by Faber and Dickey (1925) in thrush, Plass and others (1931) in monilial vulvo-vaginitis, Gomez-Vega in monilial paronychia and by Ormsby (1938) in different monilial affections.

PART I. PURULENT FOLLICULITIS

Acton and McGuire (1929) fully described a condition of purulent folliculitis common in India and elsewhere in the East the cause of which had hitherto been unknown. The results of their work may best be described by quoting their conclusions in full:

'(1) In India there is an intractable folliculitis attacking the upper part of the hair follicles of the beard area, neck, chest, arms and legs which is known as "coaly itch".

(2) The lesions are more commonly seen in men than women and chiefly amongst the poorest classes.

(3) The infection is due primarily to a ringworm fungus with secondary staphylococcal infection.

(4) The fungus is closely allied to the *Achorions** in its morphological characters.

(5) It differs slightly in cultural characters, etc., from the species now known as *Trichophyton violaceum*, but not sufficiently to justify its description as a separate species.

(6) The disease can now be cured by the application of a 5 per cent gentian violet solution painted on the area three daily for three weeks.

(7) When marked induration of the corium is present, epilation of the hairs by x-rays may be necessary to bring about a cure'.

Since that time gentian violet has been in regular use in the dermatology department of the Calcutta School of Tropical Medicine for the treatment of this infection as well as for ringworm of the foot and allied conditions commonly known as 'mango toe'. Because this trichophyton infection is practically always complicated by a staphylococcal folliculitis it was felt that a combination of two dyes, one of which was particularly fungicidal and the other bactericidal, might result in the production of a better remedy than gentian violet alone. In the course of a series of experiments on the effect of various dyes and chemicals on four species of fungi including *A. violaceum* the report of which was published by Maplestone and Dey (1938) it was found that brilliant green was a very good fungicide but not so powerful a bactericide as was crystal (or gentian) violet. A combination of these two dyes resulted in a greatly enhanced fungicidal effect and a bactericidal effect equal to that of crystal violet alone. Because crystal violet is much more expensive, even if allowance is made for its greater strength than gentian violet on account of the latter containing impurities, gentian violet was used as it is as powerful as crystal violet in its effect.

A solution of gentian violet 5 per cent in 20 per cent alcohol was the strength adopted by Acton and McGuire but an excess of dye was

(Continued from previous page)

Summary

1. The blood test as employed in excluding paternity or maternity has been defined and explained.

2. The legal position of the test has been indicated.

3. Tables of possible and impossible parents and offspring have been given.

4. Arrangements for the performance of the test have been detailed.

A list of easily available publications is given below. For consultation in person, most biologists and anthropologists are competent consultants.

watery solution of gentian violet was advocated by Percival (1936) and Florance (1936) as an

alcoholic solution was stated by them to be irritating. Our opinion is that alcohol is a better solvent than water, and this solution dries more rapidly than a watery solution; this is an important practical point in the hot, wet season of the year when the skin surface is always more or less moist. Also we do not find that alcohol in 10 per cent strength has ever caused irritation in the conditions for which it is applied to the skin by us. Therefore the lotion we first used was one containing 2 per cent each of gentian violet and brilliant green in 10 per cent alcohol.

A certain number of patients complained of mild irritation, so the dyes were reduced to a strength of 1 per cent each leaving the alcohol in strength of 10 per cent and no further complaints of irritation occurred.

Method of treatment.—The patient is told either to puncture the pustule at the root of the hair with a sterile needle or to pull out the hair with a pair of forceps. The latter is preferable so the patient is encouraged to pull out as many hairs as possible. The pus is carefully swabbed with a piece of dry cotton-wool so that it may not spread to and infect the other follicles. This operation is repeated daily till the eruption subsides. A solution of brilliant green and gentian violet 1 per cent each in 10 per cent alcohol is dabbed twice daily on the affected hair follicles. The dye should not be removed with soap and water as all our patients are tempted to do, because the presence of free alkali in soaps irritates the skin and moreover by washing there is a chance of spread of infection to the surrounding hair follicles. The patient is told to clean the affected area with alcohol once a week, preferably on the day of attending the department for examination, so that the hair follicles may be clearly visible. Methylated spirit has been used by many of our patients without any appreciably bad effects.

When these instructions are carefully carried out patients improve quickly. If there is a scaly eczematous condition present as is sometimes the case we use in addition an astringent lotion containing 120 grains of zinc sulphate and 80 grains of copper sulphate to a pint of water.

The attached table records some of the cases treated by the combined dye.

PART II. INTERDIGITAL AFFECTIONS

Interdigital affections of the hands and feet are very common in the tropics. These may be due to one of the following causes:—

(1) The commonest is infection with *Epidermophyton floccosum* (*E. cruris*), the cause of common ringworm of the body. This usually affects the interdigital space between the fourth and fifth toes. It is commonest amongst those whose work causes the feet to remain wet for long periods together. It also affects Europeans and others in the tropics whose feet are habitually moist from excessive perspiration on

TABLE I

Showing results of treatment of a number of cases of *Achorion violaceum* var. *indicum* infection with a combined solution of brilliant green and gentian violet. All were adult males

Cases marked 'improved' ceased attending before cure was complete.

account of being covered by shoes and socks. This condition is so common that no clinical description is necessary.

(2) The second condition, as mentioned by Acton and McGuire (1931), is caused by *Actinomyces keratolytica*. Two types have been ascribed to this infection. The first is the 'deep type of fissured mango toe'. The fissures extend through the thick skin of the soles and are deeper than those in a similar affection caused by the ringworm fungus. The condition is painful and is liable to secondary streptococcal infection. In the second variety the infection starts as an intertrigo and extends in a gyrate manner on the palms and soles exposing a raw surface. Infection with *Actinomyces keratolytica* is common in those who walk bare-footed or work in mud or manured soil and it is therefore very common amongst cultivators.

(3) This type of interdigital affection is caused by yeast-like organisms (monilia, saccharomyces, etc.) and is commonly seen on the palms but also has been described on the foot by different workers. In Calcutta we have found yeast-like organisms in the interdigital spaces of the toes but always in association with ringworm infection.

Intertrigo saccharomycetica is a form of dermatitis caused by yeast-like organisms. This condition has been described by Whitfield (1908) in England, and Phalen and Nichols (1908) in the Philippines. Kaufmann-Wolf (1914) in Germany, and Gougerot and Gancea (1914) in France recognized an interdigital affection caused by monilia and confirmed it by finding mycelia and spores in the scales and growing *Oidium albicans* in culture. Fabry (1918) gave this interdigital affection a special name 'erosio interdigitalis blastomycetica'.

This condition is common in women who immerse their hands frequently in water while washing and cleaning utensils and clothes. The skin in the web of the fingers is made sodden from the action of alkalis in the cleansing substances.

The disease may start as a superficial sealy erythema or a blister. In the lesions we generally find a plaque of heaped-up white sodden epithelium surrounded by a narrow, erythematous margin which may be gyrate in shape. On the hand generally the webs on either side of the middle finger or the third interdigital space may be affected first and from here the infection spreads to the other interdigital spaces or even to the nails, causing paronychia.

Treatment.—In the treatment of these interdigital affections we have used the same solution containing brilliant green and gentian violet. The part should be cleaned and dried and then painted with the above solution twice daily. It is very important that the affected part should be kept dry during and after the course of the treatment. If necessary the part may be dusted with an antiseptic dusting powder. Ordinary cases respond with this treatment very well. In neglected cases particularly in the feet where secondary streptococcal infection has occurred, cellulitis of the foot is not uncommon. In these cases routine treatment for cellulitis should be adopted in addition to painting the part with the above solution twice or thrice daily.

PART III. PARONYCHIA

This is an inflammatory condition of the nail fold. Two types of organisms may be responsible for this affection. The first one is *Actinomyces keratolytica* according to Acton and McGuire (1931).

The second one is a yeast-like organism and has been mentioned by Kumer (1921), Shel mire (1925) and others. The infection is favoured by constant soaking of the hand especially in water containing alkalis.

There is inflammation of the paronychia tissue which is characterized by 'bolsterlike swelling' and tenderness of the soft tissue lining the nails. The space between the nail and euticular fold remains gaping and from this space a whitish or watery discharge exudes on pressure. The gaping may be so prominent that a platinum loop can be easily introduced for collection of the material for examination. The disease starts at first on one nail and other nails become affected if the infection is allowed to persist. The diseased nail becomes deformed and shows an irregular surface or transverse furrows.

The material recovered from the affected part often shows mycelia and spores and culture on Sabouraud's medium produces an abundant growth of the infecting organisms. In Calcutta we found monilia infection in many of these cases.

Shel mire (1925) pointed out that these cases were extremely resistant to treatment.

We have treated these cases of paronychia with the gentian violet brilliant green mixture. The affected part is painted twice daily with a fine-pointed cotton-wool swab so that the solution may reach the space between the nail and paronychia tissue and cure is generally effected in about a month.

SCHICK TEST AMONGST A GROUP OF INDIANS AND ANGLO-INDIANS IN CALCUTTA

By C. L. PASRICHA

MAJOR, I.M.S.

K. BANERJEE

and

RUTH F. WORDSWORTH

(From the Department of Bacteriology and Pathology,
School of Tropical Medicine, Calcutta)

THE results of the Schick test carried out in certain tropical countries have shown that there is a higher degree of immunity to diphtheria (as judged by a higher proportion of Schick-negative reactors) in the inhabitants of the tropics than is found in those who live in temperate or cold climates. Further, this immunity is acquired earlier in life in the tropics than in

to stimuli received by contacts with diphtheria bacilli and their products. Amongst the well-to-do classes the chances of contact with diphtheria bacilli are considerably less than in the poorer and more densely populated parts of big towns.

In India, as in other tropical countries, although the prevalence of clinically recognizable forms of diphtheria is very much lower than in temperate climates, the antitoxic immunity has been shown to be much higher. Fox, McDonald and McCombie Young (1923) were the first to carry out a Schick-test survey in India amongst 265 European children and 6 adults from three schools in Shillong during an outbreak of diphtheria. Rambo (1929) recorded the result of 193 tests in Indians in Mangeli, Bilaspur district, Central Provinces, and Das (1934) carried out a Schick test on 284 Indians in Naini Tal district. The results obtained by these three workers are summarized in table I.

TABLE I

Showing the results of Schick-test surveys carried out by previous workers in India

Race	Fox <i>et al.</i> (1923)				Rambo (1929)				Das (1934)

other parts of the world. Certain workers have recorded that this antitoxic immunity to diphtheria was more marked amongst the local inhabitants than in European children living in the same place. That this difference in antitoxic immunity is not a result of any racial peculiarities but the result of environmental conditions has been well shown in a critical survey of the literature by Dudley (1929) and Doull (1930). These and other workers have shown that age, race, social conditions or nutrition have in themselves very little or no influence on naturally-acquired antitoxic immunity except in so far as they influence the contact between man and the diphtheria bacilli. The development of antitoxic immunity is not due to physiological processes dependent on race or age, but to the response on the part of the body

Through the courtesy of Dr. R. A. O'Brien, Director, Wellcome Physiological Laboratories, a supply of Schick toxin was sent for trial in Calcutta. Part of the supply was sent by air in a thermos flask and part in cold storage by steamer direct to Calcutta. After receipt the test-toxin was kept at a temperature of -6°C . in a box in the freezing chamber of an electrical refrigerating machine. When required to be taken out for use the toxin was placed in a thermos flask containing a lump of ice. Both the supply received by air and by the steamer gave clear-cut results. When tested on known Schick-positive reactors two months after the date of expiry the toxin was found to give well-marked reactions.

The test was carried out according to the recognized standard methods, and readings were

made after 2, 4 and 7 days. The majority of the Indian children tested were drawn from very low economic strata of society living in densely crowded areas of the city. The Anglo-Indian children were living in much better conditions, the majority of them being inmates of well-run residential schools. The 31 Anglo-Indian adults examined were nurses from one of the local hospitals. The results obtained are given in tabular form.

TABLE II

Showing the Schick-positive reactors in the Indians and Anglo-Indians tested

	Indians	Anglo-Indians	Total
Number tested	104	137	241
Number of Schick-positive reactors.	23	68	91
Percentage of Schick-positive reactors.	22.1	49.6	37.8

judged by the number of carriers, is not less common in India than in temperate climates. The immunity however is acquired earlier in life, particularly in those who live in congested areas under conditions which are ideal for the dissemination of diphtheria bacilli.

The results obtained in Calcutta and those obtained in other parts of India suggest that in each age group the Indian children show a much higher grade of immunity than the Anglo-Indian children. At first sight it appears that the ability to respond to the specific immunization is greater in case of the Indian than the Anglo-Indian and that we have an example of racial variation in susceptibility of individuals belonging to different races living under the same general environment. A closer study of the environmental conditions of these two groups showed that, whereas the Indian children tested were living under conditions which exposed them to a more intensive stimulus during the earliest year of their lives, the Anglo-Indian children led a more sheltered life. Schick tests done in

TABLE III

The Schick-positive reactors in different age groups

Age group	INDIANS			ANGLO-INDIANS		
	Number tested	Number positive	Per cent positive	Number tested	Number positive	Per cent positive
6-12 months	2	1	..
1-3 years	6	8	5	62.5
4-6 "	41	38	20	52.6
7-9 "	46	46	21	44.8
10-12 "	11	12	8	66.7
19-26 "	31	12	38.7

Unfortunately it was not possible to extend these observations with the amount of Schick toxin available. Although one must be cautious in attempting to draw any definite conclusions from data as scanty as those presented here and recorded previously in India certain suggestions can be reasonably made.

The Schick test has been used extensively throughout the world and is recognized almost universally as a reliable index of susceptibility to or immunity against diphtheria. If the immunity, as demonstrated by the Schick test, be interpreted as being due to previous specific infection it follows that diphtheria infection is not less common in Indian than in European or American cities where clinically recognized forms of the disease are of comparatively frequent occurrence. Vardon (1923) found 49 carriers of diphtheria bacilli amongst 1,000 persons drawn from different parts of India whom he examined in Kasauli and who had gone there for antirabic treatment. Of the 49 diphtheria strains isolated 7 were virulent. This carrier survey, which should be repeated in different parts of India, shows that infection with diphtheria bacilli, as

a small series of 12 Indian children living under better environmental conditions gave results comparable to those obtained in Europe or America. There is probably no real racial difference in immunity to diphtheria, and results which suggest such difference do not take into consideration the various social and economic factors which undoubtedly play a very important rôle in the development of natural immunity.

The results obtained in Calcutta and in other parts of India suggest that the absence of clinical diphtheria is probably more apparent than real and that every effort should be made to exclude infection by diphtheria bacilli even in mild and atypical infections of the throat or nasopharynx.

That 12 (39 per cent) of the 31 nurses of the age group 19 to 26 years were Schick-positive, or susceptible to diphtheria, stresses the importance of this test. It has been shown by several workers that with the introduction of Schick test and active immunization of susceptible nurses and the domestic staff of fever hospitals the incidence of diphtheria amongst the staff of these hospitals has been reduced to insignificant

MALARIAL INFECTION IN THE PLACENTA AND TRANSMISSION TO THE FŒTUS

By B. M. DAS GUPTA
(Calcutta School of Tropical Medicine)

DR. C. STRUCKLAND kindly gave the writer a blood film which was taken from a 15-hour old baby of a mother who had been suffering from *Plasmodium vivax* infection during pregnancy. The smear showed a large number of parasites (benign tertian) in various stages of development, from the ring stage up to maturity, including some aberrant forms. This finding has

(Continued from previous page)

proportions. The evidence in support of the value of active immunization of those susceptible is so strong that there can be no reasonable doubt as to its effectiveness in protecting an individual against diphtheria.

Summary

(1) A series of 241 residents in Calcutta have been tested for susceptibility or immunity to diphtheria by the Schick test; 91 or 37.8 per cent of these were Schick-positive reactors.

(2) Of the 137 Anglo-Indians tested 49.6 per cent possessed no immunity to diphtheria whereas of the 104 Indians tested 22.1 per cent were non-immune. The greater immunity amongst the Indians is better seen in the different age groups. It is suggested that the differences in immunity seen in Indians and Anglo-Indians is not based on racial peculiarities but on differences in environmental conditions.

(3) The importance of Schick test followed by active immunization of susceptible nurses and other staff of fever hospitals or diphtheria wards, where risk of infection is unusually high, is stressed. That there is a need for this is shown by the finding of a high percentage (39 per cent) of nurses who possessed no natural antitoxic immunity to diphtheria.

(4) Schick-test toxin can be imported without any loss of potency either in a cooled thermos flask by air mail or in cool storage by steamer. It can be stored in any domestic type of refrigerator without showing deterioration. The test itself is so simple to perform and economical of time as to permit of its widespread application to large samples of the population in different parts of India.

already been reported (Das Gupta, 1939). The occurrence of mature schizonts in the blood of the infant 15 hours after birth proves beyond doubt that the infection was acquired *in utero* at least 33 hours before birth.

It is now generally believed that, although a rare condition, congenital malaria does occur when there is failure of the protective effect of the placenta. The protective action fails when there is any injury (during pregnancy) resulting in placental hæmorrhage. Dr. Baird, who was in charge of the patient mentioned above, informed the writer that the mother gave no history of even slight injury at any time during pregnancy.

With a view to studying the effect of malarial infection on pregnant monkeys with reference to the possibility of transmission to the fœtus, we inoculated a pregnant *rhesus* monkey with *Plasmodium knowlesi*, a species of simian malaria parasites that produces a very virulent infection in *rhesus* monkeys, causing the death of the animal if prompt treatment is not accorded.

Experimental

A recently trapped well-nourished specimen of *Silenus rhesus* weighing 11 kilogrammes was purchased from a local dealer. The animal was in advanced stage of pregnancy as verified by skiagraphy. It was inoculated intravenously with 0.5 c.cm. of monkey's blood showing a heavy infection with *P. knowlesi*.

Six days (usual incubation period) later, its blood was examined daily for eight days. As there was no evidence of infection, it was re-inoculated with approximately four times the original dose. On the third day of the second inoculation, scanty ring forms were detected in the thick film. Gradually the parasite count increased and the animal became more and more anæmic. On the ninth day, it became severely ill, unable to sit up and refused all food. Quite a number of parasites, chiefly developing schizonts, and pigmented mononuclears were found in the blood smears. The red cell count fell to 1,600,000 per c.mm. Other evidence of anæmia such as punctate basophilia, anisocytosis, polychromasia were present. Lest the animal should not survive till the next morning, it was chloroformed at 5 o'clock in the afternoon and complete autopsy was done. The maternal organs gave evidence of acute malarial infection. The endothelial cells of the spleen and liver were found packed with large masses of pigment. The fœtal blood was rich in hæmoglobin. The red cell count was high (8,200,000 per c.mm.) as compared with that of the newly-born human baby. There were a good number of nucleated red cells. Anisocytosis was marked. Smears of the spleen, liver and bone marrow of the fœtus were carefully examined. Neither parasites nor hæmozoin pigment was found.

Placenta.—Smears prepared with the tissue snipped off the maternal surface shows a

stupendous number of parasites in different stages of schizogony and a good number of macrophages with ingested parasites and pigment. No gametocytes are seen. In sections the intervillous space is found packed with parasitized red cells and some pigmented phagocytes, the number of the infected red cells being estimated at more than 95 per cent, while the vessels of the chorionic villi are entirely free from infection.

Comment.—Although some observers have noted that congenital malaria is a common occurrence in localities where the disease is endemic; for example, Ziemann records that Weselko (Mense, 1924) in Albania attributed to congenital malaria the death in the first week of 144 children of mothers infected with *Plasmodium falciparum*. Swellengrebel (1925) records 48 cases of congenital malaria in the Near East in each of which a microscopical diagnosis was made at periods varying in time from one to five days, yet the trend of current opinion is to accept the view that the transmission of malaria from the mother to the foetus is an unusual phenomenon. This opinion has been particularly emphasized by Blacklock and Gordon (1925). These workers after a study of a large series of cases have concluded that transplacental infection of the foetus is of great rarity and may be acquired when there is a failure of the barrier action of the placenta. Lately, Garnham (1938) investigated over 400 cases to see if congenital malaria occurred. In no case could placental transmission of the malaria parasite be detected. The tremendous infection of the maternal organs especially the intervillous spaces of the placenta in the experimental monkey (plate XII, fig. 3, and plate XIII) and the total absence of the parasites or any evidence of infection in the foetus (plate XII, fig. 4) show very clearly that the protective function of the placenta is very efficient. This finding is in complete agreement with the observation of Blacklock and Gordon (1925). The protective effect of the placenta sometimes however fails, allowing the parasites to pass through and produce an infection of the offspring. This failure on the part of the placenta has been attributed to injury resulting in placental hæmorrhage, by Clark (1915), Jean (1927) and Thonnard-Neumann (1931) and others. To the present writer it seems rather more likely that the efficiency of the placenta with regard to its protective action is interfered with as a result of damage caused by prolonged parasitic invasion.

Dr. Baird's case, referred to above, may be cited as an example of the failure of the protective action of the placenta as a result of chronic infection. The patient was suffering off and on from fever (malaria) during the entire period of pregnancy with no history of injury.

That duration of infection and not so much the intensity plays an important part is also

borne out by the following facts. While investigating the possibility of placental transmission of leptospira in guinea-pigs it was often noticed that if the infected mother died at a very early stage of the disease the foetus invariably escaped infection; that if it lived a few days more very scanty foetal infection could be demonstrated by the inoculation of the foetal tissues (liver and kidneys) into young guinea-pigs, the smears of these organs being usually negative; that should the animal survive still longer, leptospiræ in fair number were found present in the sections of the liver and kidneys of the foetus. It thus follows that the longer the infected mother survived, the greater was the chance of the infection of the foetus, although the placenta showed an extraordinarily heavy infection even during the early stage of the disease. Furthermore, it has been shown that syphilis is not transmissible to the offspring if the mother acquires the infection during the last few weeks of pregnancy.

It is remarkable that the viscera of the foetus were full of blood, in marked contrast to the great anæmia of the maternal organs. Although there were a fair number of parasites in the peripheral blood, the placental sinuses were crammed with parasitized red cells. The localization of the parasites in these situations was first pointed out by Clark (1915) and later noted by Blacklock and Gordon (1925) and others, and is probably the result of partial stasis in the sinuses.

Summary

An experimental infection in a pregnant *rhesus* monkey with *P. knowlesi* was studied from the view-point of the possibility of the intra-uterine infection of the foetus. It is noted that the foetus is entirely free from parasitic invasion even when the maternal sinuses of the placenta are crammed with parasitized red cells, more than 95 per cent of the cells being infected. The blood of the mother shows extreme anæmia as a result of terrific blood destruction owing to massive infection with the parasite, in marked contrast to the florid blood of the foetus.

It is suggested that the duration of infection and not so much the acuteness is responsible for the failure of the protective function of the placenta.

I wish to express my indebtedness to Dr. C. M. Wenyon, F.R.S., who very kindly examined the materials on which these observations are based and drew my attention to the work of Garnham in this connection. I am also grateful to Professor C. Strickland for his helpful suggestions.

AN ABDOMINAL TUMOUR CAUSED BY *GNATHOSTOMA SPINIGERUM* (OWEN, 1836)

By SVASTI DAENGSVANG, D.P.H., D.T.M.

From the Department of Pathology, Siriraj Hospital,
Faculty of Medicine, Chulalongkorn University,
Bangkok, Siam

A TUMOUR and a small living round worm were removed by a surgeon from the abdominal cavity of a Siamese female, aged 27, with symptoms of intestinal obstruction and were sent to the Department of Pathology for diagnosis. The pathological examination of the tumour and morphology of the parasite are recorded as follows :—

Macroscopic description.—The specimen consisted of an irregular reddish-yellow firm tumour and a living round worm. The tumour measured $7.0 \times 6.5 \times 3.0$ cm. and was situated in the great omentum below the greater curvature of the stomach. It was apparently covered with smooth dull-looking peritoneum and at one place was overlaid by a few dark-red blood clots. On serial section it was found to be composed of greyish moist firm shiny tissue marked with many small, scattered, yellow, opaque areas and it contained a long distorted channel with the diameter about the size of a pin's head. This channel was filled with brownish turbid exudates and opened to the external surface of the tumour. A few small old hæmorrhagic areas were also observed in the tissue near this channel.

Microscopic examination of the tumour.—The hæmatoxylin-eosin stained sections of the specimen were made up mainly of oedematous cellular-adipose fibrous tissue which was very extensively infiltrated with eosinophiles and some large and small mononuclear cells. In some sections there were a few small irregular spaces filled with degenerated and necrotic leucocytic exudates. The tissue about these spaces was necrotic and more heavily infiltrated with eosinophiles and polymorphonuclear leucocytes.

These channels looked like small abscesses. One edge of the section studied was covered with a thick layer of hæmorrhagic exudate.

Description of the worm.—After careful examination, the worm was identified as an immature female *Gnathostoma spinigerum* having the following structure :—It measures, after fixation, 10.80 mm. in length and 1.04 mm. in width. The anterior end is provided with a pair of trilobate lips and a cephalic bulb which measured 0.36 mm. long and 0.58 mm. wide and is furnished with eight rows of single-pointed spines pointing posteriorly. The eighth row is still in a rudimentary stage. The body is separated from the cephalic bulb by a definite constriction and is transversely striated. The anterior two-thirds of the body are covered with tridentate and simple spines and the remaining posterior third shows none of them. The posterior end of the worm is more or less pointed. The alimentary system consists of a muscular oesophagus which measured 2.6 mm. in length, and an intestine. The latter contains a great amount of dark-red blood and opens into the subterminal anus. The vulva opens on one side of the body at the anterior part of the posterior

half of the worm. A great number of presumably young unfertilized ova are also observed in the bipartite uterus which is coiled up and down inside the body.

Unquestionably, the tumour thus described was formed as the result of the infestation by this worm. It is also interesting to note that to the best of my knowledge this is the first human case of an intraperitoneal tumour caused by *Gnathostoma spinigerum* reported in the literature.

The writer wishes to thank Dr. C. Prommas, head of the Department of Pathology, for his valuable aid and suggestions and is indebted to Dr. Khun Ketudasma for the photography.

TREATMENT OF CHOLERA (A NOTE ON THE RESULTS OF TREATMENT BY DIFFERENT METHODS)

By C. L. PASRICHA

MAJOR, I.M.S.

A. J. H. DEMONTE, D.B., I.M.D.

B. C. CHATTERJEE, M.B., D.P.H., D.T.M.

and

A. SAMAD MIAN

(From the Department of Bacteriology and Pathology,
School of Tropical Medicine, Calcutta)

ALTHOUGH in recent years considerable progress has been made in the study of the bacteriology of cholera, very little attention has been paid to the evaluation of the different methods of treatment of this disease that have been advocated from time to time or to the development of new methods of treatment. In this paper are recorded the results of treatment of cholera patients by four methods (calomel, potassium permanganate, essential oils and choleraphage) that have found favour in the hands of different cholera workers, and by M. & B. 693 (2-sulphanilyl-aminopyridine) as a representative of the sulphanilamide group that has given such promising results in a number of bacterial infections.

The different methods of treatment were carried out in the cholera wards of the Campbell hospital during the pre-monsoon epidemic and the experiment lasted for five weeks from the 27th March, 1939. The selection of cases in the different series was made by a system of coloured cards, each colour representing a particular line of treatment. The cards were so arranged that each batch of five new admissions would receive five differently coloured cards. In this way the selection of cases was made without personal bias and was irrespective of age, severity or general condition of the patient.

All the patients treated were suffering clinically from cholera and although in a number of cases the diagnosis was confirmed by the isolation of agglutinable vibrios it was not possible to undertake bacteriological examination in every one. The usual hypertonic and alkaline saline injections and other symptomatic treatment was given as indicated. The different groups received additional treatment according to the following plan :—

(i) Calomel series.—Calomel 1/8th grain was given every half hour to a maximum of eight doses. Children received proportionately smaller doses.

(ii) Potassium permanganate series.—Two enteric-coated pills of potassium permanganate (Parke, Davis & Co.), two grains in each, was given every 15 minutes for the first two hours and then every half hour throughout the acute stage of the disease. Usually 80 pills were given to each case.

(iii) Essential oil mixture series.—The mixture was made up as follows :—

Oil of aniseed ..	5 minims
Oil of eajuput ..	5 "
Oil of juniper ..	5 "
Spirit of ether ..	30 "
Aromatic sulphuric acid ..	15 "

Half a drachm of this mixture in half an ounce of water was given every quarter of an hour to a maximum of 16 doses.

(iv) Bacteriophage series.—One bottle containing 1 ounce of choleraphage was given to each patient in three doses per day.

(v) M. & B. 693 series.—Two tablets of M. & B. 693 three times a day was given for a maximum of four days.

The results obtained are shown in tabular form. In table I is given the mortality in each group without making any corrections. It was felt, however, that there might be loading in certain groups due to the inclusion of cases admitted in a dying condition and other cases which were not strictly comparable. In table II are shown the results of mortality after the following corrections had been made in each group :—

1. Exclusion of patients who died within three hours of admission to the wards.

2. Exclusion of patients below the age of six years or above the age of 50. Both the recovered and the fatal cases of these age groups were eliminated from all series.

TABLE I
Showing the total number of patients treated and the mortality in each group

Treatment	Number of patients treated	Number of deaths	Per cent mortality
Calomel ..	90	17	18.9
Potassium permanganate ..	40	6	15.0
Essential oils ..	47	5	10.7
Choleraphage ..	44	2	4.5
M. & B. 693 ..	50	5	10.0
TOTAL ..	271	35	12.9

TABLE II
The number of cases treated and the mortality in each group after the exclusion of (1) cases dying within three hours of admission and (2) patients less than six years old or more than 50 years old, irrespective of whether such patients recovered or died

Treatment	Number of patients treated	Number of deaths	Per cent mortality
Calomel ..	75	9	12.0
Potassium permanganate ..	37	4	10.8
Essential oils ..	46	4	8.7
Choleraphage ..	43	1	2.3
M. & B. 693 ..	43	4	9.3
TOTAL ..	244	22	9.0

Through some misunderstanding the number of cases admitted into the calomel series was double the number admitted into any of the other series. As the analysis of the figures was made after the completion of the whole experiment this mistake was not noticed during the course of the experiment.

Although the number in each series is small and does not justify the drawing of any definite conclusions, certain suggestions can be made. In table I the only criterion of the results of treatment has been recovery or death. Whether the patient was admitted dying or died within a few hours or whether death occurred from other causes than cholera has not been taken into consideration. All cases are taken as cholera and all deaths as due to cholera. In table II certain selection has been made and this selection is justifiable in a disease so severe and so rapid in its progress as cholera. The results obtained however are similar in both tables.

There is no appreciable difference in the mortality in the series treated with calomel, potassium permanganate, essential oils or M. & B. 693. Rogers (1937) strongly recommends treatment with potassium permanganate on the hypothesis that the toxins of cholera are albuminous in nature and, like those of snake venom, are destroyed by oxidation into non-toxic substances by the action of small quantities of permanganate. The actual results obtained do not show any advantage of the permanganate method of treatment over essential oils or calomel.

Although the only criterion taken in this analysis has been the survival or death of the patients, the general impression obtained during the experiment was that the patients treated with potassium permanganate took longer to recover and there was a tendency for the vomiting to persist longer in this series. Recovery was somewhat slow also in the patients treated with essential oils. The patients treated with divided doses of calomel or M. & B. 693, recovered rapidly and convalescence was uneventful.

The results of cholera phage therapy are striking and are sufficiently encouraging to justify the adoption of bacteriophage as a routine measure in the treatment of cholera and other methods should be compared with the results of bacteriophage therapy. The results of bacteriophage therapy in this experiment are better than those obtained in a previous trial (Pasricha, deMonte and Flynn, 1936). The bacteriophage used in this experiment was prepared by a somewhat modified method in which the strains used for the propagation of bacteriophage were added in groups at hourly intervals to the seed bacteriophage. The bacteriophage was filtered two hours after the addition of the last batch of strains of cholera vibrio.

The importance of this experiment lies in the fact that the different methods of treatment

(Continued at foot of next column)

COARCTATION OF THE AORTA

By T. K. RAMAN, M.D., D.T.M. (Cal.)

(From the Department of Medicine, Medical College and King George Hospital, Vizagapatam)

By coarctation of the aorta is meant a condition in which there is narrowing or complete obliteration at or below the isthmus of the aorta; that part of the aorta which extends between the origin of the left subclavian artery and the point of insertion of the ductus arteriosus.

Bonnet classifies coarctation of the aorta under two headings :—

(1) *Infantile type* in which there is a diffuse narrowing of the isthmus, and is usually associated with other congenital abnormalities. The ductus arteriosus is patent. In some cases the stenosis may be only of a moderate degree, while in others the isthmus may be absent altogether or reduced to a thin fibrous cord.

(2) *Adult type* the condition usually occurs after infancy and the constriction is at or below the insertion of the ductus arteriosus. Blood supply to the lower extremities is maintained by collateral circulation through the upper intercostals, internal mammary and the posterior seapular vessels. The ductus is usually obliterated but occasionally it may be patent.

Embryology

The aorta and its branches are developed from the embryonic vessels consisting of a dorsal aorta, a ventral aorta and six pairs of aortic arches.

(1) First and second pairs connect the unfused portion of the dorsal with the unfused ventral aorta.

(2) Third, fourth and sixth pairs arise from the truncus arteriosus and join the unfused portion of the dorsal aorta.

(Continued from previous column)

were carried out at the same time, during the maximum incidence of the disease, in the same ward and amongst people of more or less the same strata of society.

Summary

1. Two hundred and seventy-one cholera patients were treated by five different methods during a period of five weeks when the incidence of the disease was high.

2. The methods employed were (1) divided doses of calomel, (2) potassium permanganate, (3) essential oils, (4) bacteriophage and (5) M. & B. 693.

3. The selection of cases into the different series for treatment was based on admission and not on any personal selection.

4. The results obtained by the different methods of treatment show that bacteriophage gives the best therapeutic results.

Rogers, L. (1937). *British Encyclopædia of Medical Practice*. Vol. III, p. 166. Butterworth and Co., Ltd., London.

(3) Fifth pair arises from the ventral aorta and joins the sixth aortic arch. (This pair does not take any prominent part in the development of the aorta.)

As development proceeds, the first two aortic arches disappear, the pulmonary arteries arise from the corresponding sixth aortic arch; the dorsal portion of the right sixth arch, dorsal roots of the third and the dorsal roots of the right sixth aortic arches disappear.

In coarctation of the aorta the lesion is restricted to the dorsal root of the fourth left aortic arch lying between the origin of the left subclavian and the insertion of the sixth left aortic arch at its root (ductus arteriosus).

The condition was first reported by Paris in 1789 (Abbott, 1927); from a review of the literature, Abbott collected 237 cases, 82 of which were of the infantile type and 155 of the adult type. Blackford's review of the literature brings up the number to 127 of the infantile type and 196 of the adult type from post mortems alone.

Coarctation of the aorta has been diagnosed clinically in 78 cases and the diagnosis was confirmed by post mortem in 21 cases.

Sheldon (1932) described a case in a small boy of 12 years with all the clinical signs of coarctation of the aorta.

Lichtenberg and Gallagher (1933) reported a case in a young girl of 12 years, who came under their observation in 1930. She had all the clinical signs of coarctation of the aorta, and a hemiplegia of the left side as the result of rupture of a cerebral aneurysm.

Wilkinson (1933) presented two cases of coarctation of the aorta before the Royal Society of Medicine, one in a small girl of 4 years and 2 months; and the other in a boy of 14 years. The first child had a blood pressure of 180 systolic and 120 diastolic and very feeble pulsation in the iliac arteries, but there was no evidence of collateral circulation. In the second case there was collateral circulation and a blood pressure of 190 systolic and 130 diastolic in the upper extremities and no pulse in the legs.

Lewis (1933) reported 9 cases of coarctation of the aorta of the adult type including 3 cases where post mortem was held.

Shapiro (1933) reported the case of a boy of 7½ years which was followed for 10 years. The boy was first examined in 1923 and he was again examined in February 1924. At this time a diagnosis of juvenile hypertension in children was made. The condition was later on diagnosed as coarctation of the aorta. X-ray showed typical erosion of the ribs.

Evans reported 28 cases of coarctation of the aorta.

Pierce (1934) reported a case in an Italian labourer of 35 years. This patient died of rupture of a mycotic aneurysm of the aortic valve. The aorta was constricted 18.2 cm. above, beyond the cusp. There was no remnant of the ductus arteriosus.

Levine (1934) reported a case of cardiac hypertrophy with coarctation of the aorta of the infantile type.

Ballantyne (1935) reported 3 cases, two of which showed complete obliteration of the aorta and one moderate obliteration. The ductus arteriosus was patent in both cases of complete obstruction, and closed in the one of moderate coarctation. All these cases were of the infantile type.

Farris (1935) reported 2 cases. One was verified by post mortem.

Stott (1935) described a case in a female of 41 years without visible or palpable evidence of collateral circulation. The heart was dilated, systolic murmur was heard all over the course of the internal mammary arteries, murmurs were heard posteriorly over the apices of the lungs, blood pressure in both the arms was 220/130. There was only faint pulsation of the abdominal aorta and of the femoral arteries. X-ray showed erosion of the ribs.

Cookson (1936) reported a case in a woman of 38 years with toxic goitre.

King (1937) after a review of the whole literature has collected 175 cases in which blood pressure was taken. From the available literature one was able to collect only these cases.

As far as I am aware the condition has not been described so far in India.

Case report.—A male, aged 30 years, was admitted into a medical ward of the King George Hospital on 6th February, 1937, with breathlessness on exertion, pain in the legs and enlarged spleen of one year's duration. He is married and has two children, the first aged five years and the second three.

Examination.—A fairly well-built individual slightly anæmic with an icteric tinge in the conjunctiva, slight œdema of the lower extremities, no cyanosis. There is well-marked pulsation of the vessels of the neck. Prominent pulsating tortuous arteries can be seen on the vertebral border of the scapula and in the axillæ of both sides (figure 1). The apex beat is not visible but palpable in the fifth interspace just external to the left nipple. A systolic murmur is heard all over the chest in front and behind but is much clearer over the tortuous and dilated scapular vessels. Pulse 66 per minute with slight irregularity (auricular extra-systoles). Blood pressure 152/68 in the upper extremities and 86/68 in the lower extremities. There is very feeble pulsation in the abdominal aorta and practically no pulsation at all in the femoral and popliteal arteries. The spleen is enlarged to two finger-breadths below the umbilicus. Liver not enlarged.

Respiratory system—nothing abnormal.

Blood examination.—Red cells 1.3 million, total leucocytes 4,000 and hæmoglobin 30 per cent.

A smear showed slight anisocytosis and poikilocytosis, a few normoblasts.

Halometric reading—4.6.

Van den Bergh reaction—direct: positive delayed; indirect: positive.

Bilirubin content—2.4 units.

Blood Wassermann—(+).

Urine showed a trace of albumin; no casts. Blood urea—33 mgm.

Kidney function was estimated and showed a maximum clearance of 66.5 per cent.

Fundus was normal. There was no dilatation or tortuosity of the vessels.

X-ray of the chest showed left ventricular hypertrophy—boat-shaped heart and evidence of myocarditis. Ribs show well-marked erosion (Rossler's sign). Ascending aorta normal, not dilated; the descending aorta was not visible (figure 2).

Electrocardiogram showed regular sinus rhythm; P was normal; P-R interval was normal; left axis deviation. T+++; auricular premature contraction in lead 2; low voltage in lead 3. In lead 3 S progressively large for three beats. The clinical significance of the progressive increase in amplitude of the three beats is not known (figure 3).

Fig. 1.—Showing dilated and tortuous scapular vessels on the right side.

Fig. 2.—X-ray of the heart taken on 8th February, 1937; shows enlarged heart; descending aorta not visible; myocarditis. The erosion of the ribs (Rossler's sign) is shown by arrows.

He was kept in the hospital till the 17th March, 1937, and was discharged. The patient was asked to report and he was again examined on the 9th October, 1937.

This time the heart failure symptoms have disappeared. Spleen has reduced in size. The pulsating tortuous arteries are not so prominent as before. Systolic murmur is present all over the chest but not so clear as before. Blood pressure 166/88 in arm and 106/86 in lower extremities. Pulse was slow this time, 50 per minute. X-ray shows diminution in size of the heart.

Blood urea 48 mgm. Kidney function showed a maximum clearance of 35.7 per cent.

An electrocardiogram shows sinus bradycardia.

This case shows all the signs and symptoms of coarctation of the aorta; prominent pulsating tortuous, scapular and axillary vessels; absence of pulsation of lower extremities; slightly raised blood pressure in the upper extremities and low blood pressure in the lower; presence of systolic murmur all over the chest and x-ray evidence of erosion of the ribs. Deficient blood supply to the lower extremities has in no way interfered either with his kidney function or his reproductive function since the urea clearance is practically normal and he has two children one of 5 years and the other of 3 years.

THROMBO-ANGIITIS OBLITERANS

REPORT OF A CASE TREATED BY LUMBAR
GANGLIONECTOMY

By MIN SEIN, M.B. (Cal.), M.R.C.P. (Lond.)

CAPTAIN, I.M.S.

*Second Physician, General Hospital, Rangoon, and
Lecturer in Medicine, Burma Government Medical
School, Rangoon*

IN 1936 I published a report of a case of thrombo-angiitis obliterans which had reacted favourably to the operation of peri-arterial sympathectomy. The cure has been maintained so far and might be considered satisfactory. This case proves the utility of the operation in certain milder types of the disease.

More recently I saw a patient in an advanced stage of the disease where the radical operation of lumbar ganglionectomy had to be performed.

The patient, a Burmese male, aged 26 years, was admitted to the Civil Hospital, Toungoo, on the 2nd January, 1937, with the following history:—Twenty days prior to admission an ulcer appeared on the tip of the right great toe. This had spread upwards and involved the whole of the toe, which was in a condition of moist gangrene. The patient also suffered from excruciating and throbbing pain and had been unable to sleep. He had tried all kinds of local remedies but ultimately decided to get admitted into hospital on account of the unbearable pain. The patient had had the left leg amputated just below the knee by another surgeon two years previously on account of a similar condition spreading upwards from the toe and involving the whole foot. The patient clamoured for a similar operation for the remaining limb. He was a moderate tobacco smoker and a teetotaler.

The man was a picture of misery with sunken cheeks and eyes and dry lips due to pain, loss of sleep and loss of appetite. Physical examination was negative, except that no pulsation could be felt in the posterior malleolar and dorsalis pedis arteries. The limb felt cold and the big toe had the typical appearance of moist gangrene. There was no line of demarcation.

The limb was kept warm and an attempt was made to desiccate the ulcerated parts by frequently dabbing off the secretions and the application of methylated spirit. Hypnotics were administered at night. As there was no improvement, a femoral periarterial sympathectomy was done on the 8th January, 1937, with the hope that at least pain might be relieved. It was a forlorn hope, as one might expect from the advanced stage of the disease. However, the wound became fairly clean and a line of demarcation appeared. The big toe was amputated at the metatarso-phalangeal joint on the 19th January. The wound turned septic and gangrene spread upwards on the dorsum of the foot. The patient was calling for an amputation to relieve

him of the unbearable pain, which was as bad as before. It was decided to do lumbar ganglionectomy as a last resource. Under spinal anaesthesia trans-peritoneal lumbar ganglionectomy was performed on the right side through a right paramedian incision and the 2nd to 4th ganglia resected with their connections, on the 28th January. Within 24 hours pain was relieved and the limb appeared warmer. The patient developed fever with diarrhoea and bronchitis for ten days after the operation. The septic wound discharged pus for a considerable period and after a protracted convalescence, the patient was discharged on the 29th August, 1937, with the leg saved, the ulcers healed up and an improved general condition.

Commentary.—The lesson to be learned from the above case is that when an advanced case of thrombo-angiitis obliterans is encountered, it is better to treat it by the radical operation of ganglionectomy straight away.

I have seen two other cases amongst Burmans, besides the above two, which show that the disease must be fairly common in Asia. Therefore it may be worth while to give a résumé of the disease.

Ætiology.—Mahorner (1933) regards it as one of the most dreadful diseases which attack men. Lack of precise knowledge of the ætiology renders it more fearful. Yet certain associated factors are well recognized. For instance, it appears to be a disease almost exclusively of the male sex. Whilst Buerger, who suggested the name, thought the disease to be peculiar to Jews, it has become increasingly evident that no race is exempt. I have personally come across four cases of which the first was Chinese and the others were Burmese; all of Mongolian origin. The association of tobacco, particularly cigarette smoking, as an ætiological factor is stressed by most authorities and Silbert (1935) described a large series of cases of which there was no non-smoker. He attributed the disease to constitutional susceptibility to tobacco rather than excess, as having an important bearing on the incidence of the disease. This may partly explain the apparent rarity of the disease in Burma, as the majority of men and women smoke tobacco in this country. Perhaps a better knowledge of the disease would enable more cases to be recognized. Allen and Lauderdale (1936) put in a suggestion that the disease might be infectious in nature, as has also been suggested by Mahorner (1933) and that the transmissible agent was probably bacterial. They described a case where there was evidence of accidental transmission of the disease from man to man, e.g., a surgeon having developed the disease six months after receiving a prick on a finger whilst amputating the limb of a patient with thrombo-angiitis obliterans.

Clinical features.—Whatever the nature of the exciting cause, the underlying pathological lesions in the vessels involve two factors, e.g., ischæmia and inflammation of the deep-seated vessels, especially of the extremities, usually the legs. The arteries as well as the veins are involved in the process resulting in thrombosis, obliteration of the lumen, and subsequently

ischæmia, local syncope and death of the parts affected.

Goldsmith and Brown (1935) divide the pain as being due to several causes arising from the blood vessels, e.g., from spasm or stretching, infection, that induced by exercise, that occurring at rest, pain of ulcer or gangrene, pain of inflammatory lesions of the blood vessels and pain of complete occlusion and ischæmic neuritis. Wheeler has aptly described the condition as a pre-senile, non-syphilitic, non-embolic arterial and venous obliteration. Pain is the most prominent feature of the disease, and may be mild as when occurring only after exercise (intermittent claudication), or it may be persistent, severe and unbearable. The onset of pain or discomfort may draw the patient's attention to the disease, or the occurrence of indolent ulceration or spreading gangrene after very slight trauma to the toes which sooner or later becomes associated with pain. Clinically the condition can be recognized by the absence of the pulse in the affected arteries, and the signs of deficient vascular supply in the limb such as cyanosis, when the limb is kept pendant, blanching on being elevated, and the slow return of colour on being lowered, demonstrating the presence of both arterial and venous obliteration. Whilst the disease primarily affects one lower limb, it tends to involve the other limb as well. The disease might also affect the upper limbs. More recently Cohen and Barron (1936) have discussed the possibilities of involvement of the abdominal vessels, bringing the disease in line with thrombo-angiitis migrans.

Treatment.—The treatment can only be symptomatic, but there are advocates of both conservative and radical methods of treatment. It is generally agreed that tobacco should be given up altogether. Eradication of focal sepsis, the care and cleanliness of the feet, and avoidance of trauma are important points to remember. Barker (1935) has rightly stressed the extreme danger of minor injuries in vascular diseases such as thrombo-angiitis obliterans and arteriosclerosis.

Samuels (1934) believes in extreme conservatism, and adduced impressive figures in support of his claims. In a series of 300 cases, amputation was necessary only in one case. In addition to the above precautions he enjoined rest in bed with legs kept horizontal, and intravenous injections. He deprecates sympathectomy and ganglionectomy altogether. Other conservative measures that have been recommended are:—

(1) Application of heat, radiant or diathermic, to the limbs.

(2) Keeping the forearms in hot water (temperature 43° to 45°C.) for half an hour raises the temperature of the toes to above 31.5°C. and is assessed by Landis and Gibbon (1933) as being of the same value as T.A.B. vaccines intravenously.

(3) Typhoid vaccine intravenously, beginning with a small dose.

(4) Hypertonic salines are given by many authorities. Having treated 524 cases by this method, Silbert (1935) considers the results convincing. He injects 150 to 300 c.cm. of 5 per cent sodium chloride solution in freshly distilled water by gravity method. He gives three, two, and then one injection a week. As it is likely that the injections will be followed by rigor, it is not advisable to follow the advice of frequent injection. Samuels (1936) also recommends this procedure.

(5) Takáts (1934), Hermann and Reid (1934), Landis and Hitzrot (1935), and Collens and Wilensky (1936) recommend intermittent negative pressure where there is no actual inflammation or gangrene. Rest-pain, intermittent claudication and cyanosis are relieved and indolent ulcers are healed.

(6) Artificial fever therapy. The injection of saline and typhoid vaccines have this end in view.

(7) Administration of vasodilators such as theobromine and its salts [Scupham (1934), Scupham and Takáts (1935)] is also recommended but they do not seem to have lasting value.

(8) The use of sedatives and opiates during conservative treatment.

Radical treatment includes

(1) *Periarterial sympathectomy.*—This method seems to have gone out of favour, but a few cases are on record, as having derived permanent benefit by this operation.

(2) *Lumbar ganglionectomy.*—Most authorities are now in favour of this operation [Telford and Stopford (1933), Brown (1934), Telford (1937)]. On the other hand Fraser (1935) does not believe that the operation has any permanent effect upon the progress of the disease.

The operation is done transperitoneally by anterior approach with the patient in the Trendelenburg position and sympathetic ganglia L2 to L4, with intermediate connections, are removed on both sides. The results appear good but the operation is not easy and requires a good knowledge of anatomy.

(3) Sooner or later the onset of gangrene forces one's thoughts to the question of amputation of the affected limb. Ganglionectomy has lessened the incidence of amputation but there are some cases where the operation cannot be avoided.

It will be noted that whilst protagonists of each line of treatment might extol it to the exclusion of others, it is advisable to remember, that in any particular case more than one might be necessary.

Summary

(1) A case of thrombo-angiitis obliterans treated by lumbar ganglionectomy is described.

(2) A general summary of the disease is appended to draw the attention of the medical

TUMOURS OF THE UPPER JAW AND ITS IMMEDIATE NEIGHBOURHOOD

By V. M. KAIKINI, B.A., F.R.C.S. (Edin.)
King Edward Memorial Hospital, Bombay

THE growths that are commonly found in the upper jaw are the following :—

(1) *Epulis*.—The majority of these tumours grow from the peritosteum, periodontal membrane, or endosteal lining of the alveolus. These are of three kinds :

(a) *Fibrous epulis* is a fibroma growing from the periosteum and may be associated with a carious tooth. It is in the form of a red fleshy tumour painless and lobulated, covered by an intact mucous membrane.

(b) *Simple granulomatous epulis* consists of a mass of granulation tissue, inflammatory in origin, associated with a carious tooth or a necrosed portion of the jaw bone. It is of the nature of a polypus.

(c) *Malignant epulis* are of the nature of osteoclastoma or fibrosarcoma, of the periosteum, or periodontal membrane. They grow more rapidly than the other two varieties, and do not as a rule spring up between two teeth and form a hard elastic red sessile swelling.

(2) *Leontiasis osseum* is supposed to be an inflammatory overgrowth of the bones of the maxilla due to chronic sinus infection, and it

(Continued from previous page)

profession on account of the prevalence of the disease in Asia.

occurs in young adults giving rise to great pain. This condition is not confined to the upper jaw only, but spread to the facial and cranial bones as well.

(3) *Myelomata* arise within the alveolar process. The alveolar process becomes swollen and expanded with a dusky colour, giving rise to egg-shell crackling. The growth may fungate. They behave like malignant tumours.

(4) *Epithelial odontomes* are sometimes found in the upper jaw. They are multilocular and on account of the bony capsule, and the early degeneration of the epithelium, they have little tendency to spread.

(5) *Dentigerous cysts* are of two varieties. The commonest one is cystic only consisting of an outer bony shell of varying thickness, and an inner membranous one. An undeveloped tooth is found inside the cavity. They commence early in life and a tooth is found missing. In the other variety occurring in older patients, solid growths, sarcomatous in nature, may be found.

(6) *Dental cysts* are in connection with carious teeth, and suppuration with sinus formation is common. They are painless and slow growing.

(7) *Enchondromata* and *osteomata* have been reported; but these are rare.

(8) *Sarcoma* is more common than carcinoma and is either round-celled or spindle-celled. It grows either from the back part of the maxilla in the spheno-maxillary fossa, within the antrum, or from the front wall of the maxilla.

(9) *Carcinoma* usually commences in the epithelium of the gums or palate and invades the jaw secondarily. In this case it is squamous celled. In some cases it grows from the mucous membrane of the antrum when it is columnar celled.

Papillary leucoplakia of the mucous membrane of the upper jaw is potentially malignant. Adenocarcinoma of the mixed tumour type usually occurs posteriorly in the upper jaw and palate, and as a rule presents a non-ulcerated smooth hard surface.

Clinical signs and symptoms of malignant tumours of the upper jaw

Patients with a constant complaint of pain and uneasiness in the upper jaw or in the face, whose symptoms have been of short duration and who state that the pain or uneasiness is made worse by lying down, should be carefully examined to exclude malignant tumours, as the cause of the pain.

The majority of the cases that come to the surgeon either for diagnosis or treatment come late. A good many of these are treated for tooth or sinus trouble, and when the pain and swelling are found to increase the help of the surgeon is sought.

When the tumour grows from the anterior aspect of the maxilla the cheek is found to be pushed forward, in the beginning. Later on the

mouth and orbit are invaded, and the soft tissues of the cheek undergo infiltration. If the tumour starts from the periosteum of the posterior surface of the maxilla, it grows in the sphenomaxillary fossa and invades the orbit from behind. The eyeball is pushed forward and the nose is invaded in later stages. When the tumour commences in the antrum the first symptom is pain in the fifth nerve, and the walls of the antrum are found to bulge in all directions; the palate is depressed, the eyeball is pushed forward and upward and the cheek is found to be prominent. Eggshell crackling may be present over the swelling. There will be nasal obstruction with considerable discharge and epiphora due to the obstruction of the lachrymal duct. Puncture of the antrum will bring out blood but no pus.

Innocent swellings of the maxilla; the mycoids, dental or dentigerous cysts and empyema of the antrum may be mistaken for these tumours. But none of these conditions give rise to the pain, steady progress, infiltration of tissues, bleeding and fungation that are seen in malignant tumours.

Below are given the records of thirteen cases which were operated upon for malignant tumours of the maxilla. The majority of these cases were sarcomatous in nature, and had come in a fairly advanced condition.

Case 1.—Male, aged 35 years, admitted in October 1927 with a big round swelling on the anterior aspect of the left maxilla. There was a good deal of pain with nasal discharge and epiphora. History was of about one year's duration. Being the first operation of its kind done by me, the classical textbook methods of excision of the maxilla were tried. The left external carotid artery was tied, a laryngotomy opening made, and a laryngotomy tube was inserted through which chloroform was administered. Unfortunately the patient stopped breathing before the skin flap had been fully reflected, and his condition looked rather bad. So the skin flap was stitched and the operation was not proceeded with. The patient was sent back to the ward where he fully recovered from the effects of the operation. The second attempt to excise the maxilla was made after about fifteen days. Chloroform was administered by the open method, the laryngotomy tube being dispensed with. The usual incision extending upward from the middle of the upper lip along the outer margin of the left ala nasi, to half an inch below the inner canthus and then horizontally to the right malar bone was made, and the skin flap reflected. The whole of the maxilla was removed. It came away in three pieces, as the tumour had caused a good deal of destruction of the anterior and lateral walls of the bone. The gap was packed with gauze and the flap stitched in place. Bleeding was profuse and had to be stopped by ligaturing and gauze pressure. Convalescence was smooth. The patient complained of double vision for about a month. But the sight was normal after that period. The patient was reported to be doing well four years after the operation. The tumour was sarcomatous in nature.

Case 2.—Female, aged 23 years, admitted in December 1928, with a small swelling half an inch in diameter on the hard palate on the left side, near the alveolar margin. She at first showed it to her family doctor, who thinking it to be an ordinary abscess incised it. This gave rise to profuse bleeding and he suspected something serious, so she was advised to see a surgeon. After admission into the hospital, a section was taken from the growth, and examined. The report was 'A

rapidly growing fibroma with hæmorrhages—a fibrosarcoma'. The operation was done under general chloroform anaesthesia without a preliminary tying of the carotid artery or the use of the laryngotomy tube. The maxilla was removed in the usual way and it came out in one piece. The antrum was found to be occupied by a fairly large growth, much larger in size than the portion projecting from the hard palate. The patient's convalescence was uneventful. She was seen in September 1938, with a mild attack of appendicitis, for which she underwent an operation. The defect in her face does not cause her much inconvenience, she is able to chew her food without any difficulty, and has got an artificial denture to close the gap left after the operation. The deformity in the face also is not very disfiguring (figure 1).

Fig. 1.—Case 2. Fibro-sarcoma right maxilla. Photo taken in 1938. The right maxilla was completely removed. The deformity is very slight.

Case 3.—Female, aged 25 years, admitted on 15th July, 1930, with a papillomatous growth of the hard palate extending to the adjoining portion of the cheek. Two years previously the growth had been removed by diathermy, but had recurred. Pathological examination report of the growth was 'Papilloma probably becoming malignant'. One per cent novocain with adrenaline was injected deep into the tissues at a point half an inch in front of the margin of the opening of the external auditory meatus, thus blocking the branches of the fifth nerve in the sphenomaxillary fossa. Novocain was injected subcutaneously along the margins of the maxilla and deeply under the periosteum of the interior plate of the orbit. The patient developed good anaesthesia, and the maxilla was removed completely. The papillary growth on the adjoining portion of the cheek was also dissected out. The patient had no shock and bore the operation very well, there being very little bleeding. She was discharged in good condition. The further history could not be traced.

Case 4.—Male, aged 45 years, admitted on 10th November, 1930, with a fairly big hard fungating tumour, sarcomatous in nature on the right side of the hard palate encroaching a little on the left side. Anaesthesia was induced with novocain injected as above, and the maxilla was removed in pieces, with the patient in a semi-reclining position. The bone was completely

disorganized by the tumour. There was profuse bleeding but the patient stood the operation very well, and was discharged with the wound nicely healed. He did not report himself again, but most likely the tumour recurred in the adjoining region, as it was already too far advanced when the operation was done.

Case 5.—Male, aged 70 years, admitted on 24th January, 1931, with an advanced sarcomatous growth of the right maxilla. The patient first noticed a painless swelling of the maxilla which was diagnosed by his physician as malignant and he was advised deep x-ray treatment. He did not take the treatment but went on applying some ointment locally. The skin of the cheek was infiltrated and oedematous. The hard and soft palates on the right side were involved. The maxilla was removed under local anaesthesia. The growth was found to have invaded the base of the skull, so complete eradication was impossible. The wound healed completely except for a small opening in the skin of the cheek. Shock was practically absent and the patient was discharged free from pain and was advised radium treatment, for the portion of the growth which could not be removed. He was reported to be alive and fairly comfortable six months after the operation. Nothing was heard of him after that.

Case 6.—Male, aged 21 years, was admitted on 7th March, 1933, with a big tumour of the left maxilla of six months' duration. The swelling was prominent anteriorly and inferiorly on the hard palate where it was irregular and granular in appearance. The whole maxilla was removed by the method described above, under local anaesthesia. The severe pain complained of by the patient completely disappeared and he was discharged with the wound nicely healed. The tumour was sarcomatous in nature. Nothing further was heard of the patient.

Case 7.—Male, aged 38 years, admitted on 5th September, 1934, with a big fungating ulcer on the hard palate, about two inches in diameter, dark brown in colour, extending to within half an inch of the pillars of the fauces. About two months previously the patient noticed a small ulcer on the hard palate which was diagnosed as gummatous by his doctor, and he was given antisyphilitic treatment. But the ulcer went on increasing in size and severe pain, radiating to the ear started and the upper teeth on the left side became loose. At the same time a swelling appeared on the cheek. The maxilla was removed under local anaesthesia. The tumour was carcinomatous in nature and had involved the margins of the orbit and the base of the skull. The patient was discharged with the wound completely healed and was advised deep x-ray treatment. Pain had completely disappeared. He returned about ten months later with the left eye swollen, red, and protruding. There was no pain but the tumour was reappearing at the base of the skull. He died about four months later.

Case 8.—Male, aged 45 years, admitted on 3rd November, 1936, with a tumour, carcinomatous in nature, in the right maxilla and involving the mucous membrane of the cheek. Being an advanced case the maxilla was removed piecemeal under local anaesthesia and the ulcer on the cheek dissected out with a diathermy knife. The wound healed by first intention, and the patient was discharged. He returned after about four months with the tumour recurring in the eye.

Case 9.—Male, aged 48 years, admitted with a large sarcomatous tumour involving the right maxilla, and extending to the lateral wall of the pharynx, behind the tonsil. The patient gave a history of only three months' duration. The maxilla was removed under local anaesthesia, but the patient died of shock about eight hours after the operation.

Case 10.—Male, aged 60 years, admitted on 29th March, 1938, with a swelling on the left maxilla and inability to swallow. History was of six months' duration, and the trouble started with bleeding from the nose. The vision in the left eye was defective. There was a fungating growth on the hard palate on the left side and the alveolar process was also invaded. It was an advanced case. The maxilla was removed under local anaesthesia, and it was found that the tumour had

gone beyond the posterior wall of the maxillary antrum. The patient was discharged with the wound completely healed, and was advised deep x-ray treatment. He returned after about four months, and on examination a carcinomatous ulcer was found in the region of the pterygoid fossa. The patient was not seen after that.

In the three cases quoted below the maxilla was removed for eradicating tumours of the nasopharyngeal region. The majority of these tumours usually start from the base of the skull—from the basisphenoid or basioccipital. Less frequently they may start from the pterygoid fossa and adjacent plates or from around the posterior nares.

Case 11.—Male, aged 18 years, admitted on 26th March, 1936, with a tumour extending from the nasopharynx on the right, to the maxilla and pushing the cheek forward. Both the hard and soft palates were pushed downward. A hard nodular mass was seen in the right nasal chamber. There was proptosis of the right eyeball. Tumour bled easily when touched. Deep x-ray had been tried without any benefit. The condition of the patient was very miserable on account of pain and difficulty in deglutition, and he was begging to have an operation done on him. Under local anaesthesia both the external carotid arteries were tied and the right maxilla was completely removed. The tumour was soft and vascular, and was removed partly with scissors and partly by enucleation. This produced formidable bleeding and the patient died soon after the operation. The tumour was of the nature of a fibrosarcoma.

Case 12.—Male, aged 18 years, admitted on 21st April, 1936, for inability to swallow solid food, tinnitus right ear, and difficulty in breathing. There was a hard round tumour occupying both the lateral walls of the pharynx, and the base of the skull. The soft palate was pushed forward. There was ptosis of the right upper eyelid. Aural examination report was 'Cochlear division normal, equal both sides. Right membrane hyperæmic without bulging. Tinnitus could be accounted for by hyperæmia'. History was of four months' duration. Severe pain was present in the occipital region. The right maxilla was removed under local anaesthesia, which gave good access to the nasopharyngeal region. The tumour was a big one and was attached by a broad base to the posterior and both the lateral walls of the nasopharynx. The mucous membrane covering the tumour was separated as much as possible. It was adherent and very much thickened. The tumour was found to be very hard and fibrous in nature. It was removed in pieces partly with nibbling forceps and partly with the diathermy knife. There was very little bleeding throughout the operation. The patient was completely relieved of his dyspnoea, dysphagia and other distressing symptoms, and was discharged on the eighteenth day after the operation. By that time the ptosis of the eyelid had considerably improved.

Case 13.—Male, aged 25 years, admitted on 14th August, 1938, with a big growth filling practically the whole of the nasopharynx, which prevented him from breathing and swallowing freely. The growth was soft and the patient used to pluck out pieces from the tumour which allowed him to breathe and swallow a little more freely. This used to give rise to a little bleeding which stopped easily. The patient was in great distress on account of the dyspnoea and difficulty in swallowing. Tracheotomy had to be done to relieve the difficulty in breathing. The right maxilla was completely removed under local anaesthesia, and the growth was fully exposed. It extended from the roof of the pharynx to both the lateral walls and on the right side had extended to the epiglottis. It was very soft and polypoid in nature and was removed partly with scissors and partly with the fingers. There was a fair amount of bleeding which was easily stopped. The wound was packed with acriflavine gauze. The patient was very much relieved and within a couple of hours after the operation helped himself to a large amount of orange

juice, although some of it regurgitated through the nose. The patient was discharged in good condition. He reported himself in October 1938 and a small nodule was found growing from the site of the old tumour,

Fig. 2—Case 13 Naso-pharyngeal tumour Patient one month after the operation. The scar on the cheek is clearly seen.

for which he was advised deep x-ray treatment. The tumour was found to be a fibroma on pathological examination. This tumour is locally malignant and tends to recur (figure 2).

Summary

1. Out of the thirteen cases of removal of the maxilla, ten were for malignant growths in the maxilla itself, and three for growths in the naso-pharynx.

2. Altogether there were two operative deaths, in cases which were very far advanced.

3. Out of the ten tumours in the maxilla four were carcinomatous in nature, and the rest sarcomatous. Out of the three nasopharyngeal growths one was a sarcoma, and the rest were fibromas.

4. Out of the thirteen operations, only the first two were done under general anaesthesia. In only two were the external carotids tied. All the other operations were done under local anaesthesia without the preliminary tying of the external carotid arteries.

5. In all the operations done under local anaesthesia shock was practically nil, and anaesthesia was perfect.

THE VITAL CAPACITY OF THE BENGALLEES

By P. DE, B.Sc., M.B. (Cal.), F.R.C.P. (Edin.)
Professor of Physiology, Medical College, Calcutta
and

B. N. DE, M.B. (Cal.)
Demonstrator of Physiology, Medical College, Calcutta

THE vital capacity of individuals has, in recent years, been attracting considerable attention of medical practitioners regarding the diagnosis and prognosis in various diseases of the heart and lungs. Paramount importance has also been laid on selecting candidates for the air service where a minimum standard has been fixed for admission of cadets. In diseases of the lungs, specially in pulmonary tuberculosis, the vital capacity is definitely lowered and the reaction of patient to treatment can be judged by the increase or decrease of the vital capacity.

As early as 1846, Hutchinson (1846) observed that the vital capacity in phthisis was definitely lowered. A diminution of 16 per cent below normal was looked upon as suspicious and in late cases a diminution of 2,000 c.cm. might be found. Arnold (1855) believed, that the vital capacity was not only important in diagnosis but also on the severity of infection and on the results of treatment.

Dreyer and Burrell (1922) specially investigated the importance of vital capacity in diagnosis and prognosis of patients suffering from diseases of the heart and lungs. The vital capacity was diminished in those diseases in which the airways became filled with secretions and also in conditions in which the lungs were compressed. Thus, diminution of the vital capacity was found in pneumonia, bronchial catarrh, emphysema, empyema, asthma, hypertrophy of liver and spleen.

Peabody and Wentworth (1917) observed that the vital capacity in heart diseases was diminished and stated that determination of vital capacity offered a clinical test as to the functional efficiency of the heart, since compensated

(Continued from previous column)

6. Early removal of the maxilla for malignancy gives brilliant results. So early diagnosis is very important.

7. Any swelling of the upper jaw with pain or uneasiness, which grows worse on lying down and in which the alveolar process on the affected side looks inflamed and swollen, with looseness of the teeth, must be viewed with suspicion and a thorough investigation must be made in such cases to exclude malignancy.

8. Even in advanced cases of malignant tumours of the maxilla, where the maxilla was excised, and the patient died of secondary growths, death was less painful than it would have been had the bone not been completely removed.

cases which did not suffer from dyspnœa had a normal vital capacity according to their method of calculation.

From a consideration of these important observations we took up the question of finding an average standard of vital capacity for the people of Bengal living under the same environmental conditions, food, general habits, etc.

Thackrah (1831) examined the vital capacity by using a large graduated glass jar which was filled with water and inverted in more water. The individual blew through a tube the other end of which was introduced under the jar. His observation showed 6 to 10 pints as the vital capacity in man and 3½ pints in woman.

John Hutchinson (1846) made an extensive study of vital capacity on over 2,000 persons and observed that with increasing height the vital capacity increased in a simple arithmetical progression, and that for an increase of every inch of height from 5 to 6 feet an additional amount of eight cubic inches of air at 60°F. is given out by a forced expiration. He also observed the influence of weight on vital capacity. He did not find the existence of direct relationship between vital capacity and circumference of chest though the degree of mobility of the ribs had definite influence on vital capacity. He stated that the vital capacity was influenced by the bodily position in which the observation was taken, chiefly because of altered mobility of the ribs which was greater while standing than sitting, and while sitting than lying. He also observed the influence of age on vital capacity which increased up to 35 and then decreased to 65, and of sex, being greater in the male than the female. The variation of the vital capacity in individuals in different occupations was observed by the same worker.

Arnold (1855) concluded that vital capacity increased with the standing-height and that sitting-height was not of greater value. He considered chest measurement of value specially if 5 to 6 cm. be deducted for fat subjects and 5 cm. added for thinner ones. He considered the weight only so far as it was influenced by height.

Peabody and Wentworth (1917) in America demonstrated a relationship between vital capacity and surface area. They graded healthy individuals according to sex and height:—

	Height	Vital capacity
Males	{ 6 ft. and over	5,100 c.cm.
	{ Over 5 ft. 8½ in. to 6 ft.	4,800 "
	{ 5 ft. 3 in. to 5 ft. 8½ in.	4,000 "
Females	{ 5 ft. 6 in. and over	3,257 "
	{ Over 5 ft. 4 in. to 5 ft. 6 in.	3,050 "
	{ 5 ft. 4 in. and less	2,825 "

He observed that in the case of males 2,660 c.cm. could be taken as the average vital capacity per square metre of body surface.

Dreyer (1919) after extensive work on vital capacity laid down formulæ showing the relationship between vital capacity, body weight, stem length and chest circumference.

In this paper we have recorded the age, weight, standing height and vital capacity of 100 students of Calcutta Medical College and have discussed their vital capacities in relation to surface area. The subjects came from different parts of Bengal with different modes of life and activities. The vital capacities have been recorded by means of Verdin's spirometer. The subject sat on a high stool with his back straight and was carefully instructed how to breathe into the spirometer. The recording dial was covered from his view to eliminate psychological effects. Five records were taken and the maximum noted. The vital capacity thus found was reduced to 30°C. and 760 mm. of mercury pressure, the temperature and barometric pressure being observed during the experiments. The surface area of the body was calculated from Du Bois' formula.

$$S = W^{0.425} \times H^{0.725} \times 0.007184$$

The result of our observations is given in table I.

The average vital capacity per square metre of body surface as calculated from table I is 1,790 c.cm. Whereas in America Peabody and Wentworth found it to be 2,660 per square metre of body surface, our figures vary from 1,519 to 2,198 as shown in graph 1.

It will be seen from this graph that the vital capacity per square metre of body surface is between 1,700 to 1,800 c.cm. in 31 per cent of our cases. In 68 per cent the vital capacity falls between 1,600 to 1,900 c.cm.

During our observation we found several cases with vital capacity below 1,500 c.cm. per square metre of body surface. On investigation those cases revealed either some past history of diseases of heart or lungs or showed definite

lesions still present (table II). As regards the cases with vital capacity above 2,000 we found

GRAPH 2

after investigation that those cases led very active outdoor lives. For example, in table I

case 2 with a vital capacity of 2,198 c.cm. per square metre of body surface was born and brought up in Shillong which is over 5,000 feet above sea level and he is a good athlete. Case 13 with a vital capacity of 2,157 c.cm. per square metre body surface is a good athlete and plays football, hockey and cricket regularly. Cases 19, 21, 22, 45, 49, 78, 80 and 94 give similar histories.

Dreyer (1919) in England investigated a series of 16 cases taking weight, height, stem length and chest circumference as his data, but he did not take surface area into consideration. In order to compare our figures with his, we took his data of height and weight and calculated the surface areas and so worked out the vital capacity per square metre of body surface, as shown in table III. In his cases the maximum is 2,589 c.cm. and minimum is 2,130 c.cm. with an average of 2,383 c.cm. On grouping these cases, as shown in graph 2, we find that the maximum number, about 37½ per cent, falls between 2,300 to 2,400 c.cm. per square metre of body surface.

We thus have three sets of data, namely, those relating to normal and diseased Bengalee and English persons. Table IV sets out the arithmetical means, standard deviations and the probable errors of the means for these three groups.

TABLE I
Results of examination of 100 healthy Bengalee students

TABLE III

Dreyer's figures from which surface area has been calculated for purpose of comparison

Number	AGE		Weight in gm.	Height in cm.	Surface area in sq. metre	Vital capacity in c.cm.	Vital capacity in c.cm. per sq. metre of body surface
	Years	Months					
1	51	10	88,800	186.0	2.148	5,130	2,389
2	35	1	63,500	172.0	1.751	4,440	2,536
3	31	7	74,600	184.5	1.972	4,660	2,363
4	27	11	63,500	172.0	1.751	4,200	2,399
5	43	3	69,100	164.2	1.756	4,400	2,506
6	31	3	63,500	171.0	1.744	4,200	2,408
7	35	2	77,400	172.5	1.910	4,800	2,507
8	25	0	81,000	184.0	2.040	4,890	2,397
9	25	0	63,500	171.0	1.744	4,160	2,385
10	28	9	56,300	160.5	1.583	3,830	2,418
11	22	0	66,900	179.6	1.847	4,400	2,383
12	24	0	81,100	178.0	1.992	5,140	2,589
13	18	1	58,600	168.8	1.669	3,800	2,277
14	14	6	41,200	150.0	1.320	3,030	2,295
15	13	9	38,900	156.0	1.326	2,840	2,142
16	12	10	29,800	140.0	1.094	2,330	2,130
							Average 2,383 c.cm.

TABLE IV
Comparative table

Sample	Mean vital capacity per square metre body surface	Standard deviation	Probable error of the mean vital capacity
Normal Bengalee	1,790.02	156.38	10.55
Diseased Bengalee	1,390.20	118.10	35.62
English persons	2,382.75	126.53	21.34

Statistical test of significance shows that the difference between the mean vital capacities of normal and diseased Bengalees cannot be regarded as a chance occurrence. The difference between the normal people of Bengal and of England is also significant statistically.

From a comparison of the figures for vital capacity of people in America and the British

Isles with those of ours, it will be observed that in America and England the vital capacity per square metre of body surface is higher than that found in Bengal.

We wish to acknowledge with thanks the suggestions and help that we have received from Dr. L. E. Napier, Officiating Professor of Tropical Medicine, Calcutta School of Tropical Medicine, and Dr. R. B. Lal, Officiating Director, All-India Institute of Hygiene and Public Health, in connection with this paper.

Summary

1. Observation of normal healthy cases showed that the vital capacity of average Bengalee youths of 17 to 23 years of age is 1,790 c.cm.

2. Low vital capacity, observed in our cases showed present or past history of some disease of heart or lungs.

PRELIMINARY TUBERCULOSIS SURVEY OF RURAL AREAS IN THE PUNJAB

By ILAHI BAKHSH, M.D. (Lond.), M.R.C.P. (Lond.)
MAJOR, I.M.S.

Professor of Pharmacology and Therapeutics, K. E. Medical College and Physician to Out-patients, Mayo Hospital, Lahore

TUBERCULOSIS is said to be on the increase in India. The remarkable progress motor traffic has made during the last two decades has greatly facilitated intermingling of the rural and urban populations. There is no doubt that tuberculosis is rife in the congested areas and slums of Indian towns but very little information is available about its incidence in the villages.

With perhaps one exception no reliable survey of tuberculosis has so far been conducted in the Punjab. It was on the suggestion of Colonel G. G. Jolly that I took up this work during Christmas vacation.

The number of people examined is admittedly small but it is hoped that the experience gained and the information given below may be of some help to those who wish to undertake this type of work in the present campaign against the scourge of tuberculosis.

The Tuberculosis Survey Committee, Indian Research Fund Association, recommends four types of survey: Type I survey is a preliminary survey dealing with rate and distribution of infection and is ascertained by testing every individual with tuberculin. Type II, III and IV surveys are more detailed and are concerned with extent and nature of active infection, disease and mortality rate, etc. The present paper deals with type I survey only.

The villages selected were Mirpur and Muzaffarpur in Nakodar Tahsil, Jullundur District, for the following reasons:—

(1) Both the villages are situated at a considerable distance from the nearest town. Muzaffarpur is nearly $2\frac{1}{2}$ miles from Nakodar (population about 10,000) while Mirpur is at a distance of $1\frac{1}{2}$ mile. There is no motor traffic between Nakodar and these villages. The market place in Nakodar is situated about half a mile outside the town but the villagers rarely

(Continued from previous page)

3. Cases with vital capacity above 2,000 c.cm. per square metre body surface led active outdoor lives.

go there to sell their merchandise because the inhabitants are only small landholders and their produce is only just enough to meet their own requirements.

The inhabitants are almost entirely Muslims excepting a few sweepers and they belong to the agriculturist class called Arains. There is practically no purdah in these villages, the women work with the men in the fields. The villagers spend most of the day in the fields. At night time in summer they sleep on top of their roofs or near their cattle in the open spaces adjacent to the village. In winter they sleep in mud houses which have very few windows and ventilators. The cattle sheds are separate from the sleeping rooms and nobody was found to sleep in the same room occupied by the cattle. Muzaffarpur is less congested than Mirpur where the people are somewhat poorer and live in much smaller houses.

From the above it is clear that both the villages are typically rural and isolated from the influence of neighbouring towns. Unlike other villages in Jullundur District there are only one or two men in each village who have been abroad. In some of the villages in this district 20 to 30 per cent of the men have visited America, Europe, Africa, China and Japan.

Before the enquiry was started co-operation of the administrative authorities was secured by personal interviews and the inhabitants were lectured on the broad principles of this work. Fortunately the local public were indebted to me for having treated their sick on many occasions during college vacation. Objection to being 'pricked' was therefore insignificant and this was overcome by tactful and gentle persuasion.

Through the generosity of Messrs. Merck & Co., I was supplied with large quantities of their special preparations including cod-liver oil, vitamin-B, -C and -D preparations and other expensive drugs far beyond the reach of these poor villagers. In winning the confidence of these half-educated and backward people the importance of rendering specialized medical aid and distribution of medicines right in their own homes cannot be over-emphasized.

The staff consisted of three doctors including myself, a lady health visitor, and two peons. The lady health visitor unfortunately was not available for the whole period. The co-operation of a lady doctor would have been of much more use. Most of the clerical work was done by two *patwaris* and educated volunteers from both the villages.

The *patwaris* were told to prepare the lists of all the inhabitants according to families and these were entered on printed forms giving name, race, age and family with special columns for height, weight, physical examination and Mantoux test. Special attention was paid to the clinical examination and any abnormality found was noted in a special column. The Mantoux test was done according to the

directions given in the pamphlet issued by the Tuberculosis Survey Committee, Indian Research Fund Association, particular care being taken to maintain uniformity of technique. On each day 10 families were told to stay in their houses in the morning and the same number in the afternoon. In this way the inhabitants were put to least inconvenience and their work did not suffer much.

In taking histories the facts were verified in the presence of the village headman who usually knows a good deal about every one. Tuberculin injections were then performed with 1/1,000 dilution in every member of the family except those suspected of having any tuberculous lesion, suspected contacts or very young infants who were injected with 1 in 10,000 dilution.

Results were read after 48 hours and if negative stronger dilutions (1 in 100 in the case of apparently healthy adults and 1 in 1,000 in others) were injected on the 4th day. Reading of results was very tedious as it was difficult to catch inoculated men, who, thinking that our work was over, had left for their fields and sometimes had to be followed there. In spite of all our efforts, 10 per cent of the population escaped investigation.

The following graphs illustrate the incidence of infection among the villagers.

MANTOUX TEST

CHART 1

Village.....Mirpur.

Total cases examined.....330.

MANTOUX TEST

CHART 2

Village.....Muzaffarpur.

Total cases examined.....233.

None of the children under 2 years reacted to tuberculin and the curve rose steadily with age until it reached 58 per cent between 20 and 30 years. Muzaffarpur on the other hand showed a higher incidence. The curve is steeper, the percentage of positives being 73.1 between 20 and 30 years and 76.9 above 30 years. The infection according to sex does not show any marked difference in both the villages.

The intensity of the tuberculin test is given in the following table :—

MUZAFFARPUR

Intensity of reactions.	Negative	+	++	+++	++++
Males ..	49	41	22	4	2
Females ..	48	29	16	19	3
TOTAL 233	97	70	38	23	5

MIRPUR

Intensity of reactions.	Negative	+	++	+++	++++
Males ..	115	29	24	8	0
Females ..	100	17	29	8	0

SCARABIASIS OR THE PRESENCE OF BEETLES IN THE INTESTINE

By C. STRICKLAND, M.A., M.D.
Professor of Medical Entomology
and

D. N. ROY, M.D., D.T.M.
Assistant Professor of Medical Entomology,
School of Tropical Medicine, Calcutta

THE occurrence of dung-beetles in the stools of persons is a condition that has been called

(Continued from previous page)

It will be noticed that it is definitely less in Mirpur than in Muzaffarpur. Of the 5 persons giving ++++ reactions, only two gave history of contact, while one, a boy of 21, looked very suspicious but physical signs were negative. There were 23 persons giving +++ reactions in Muzaffarpur and out of these only 8 had a history of contact. None of these showed any physical signs of active or quiescent disease. In Mirpur there were only 16 persons with +++ reactions and none of them had a definite history of contact. None of these showed any physical signs of tuberculosis.

Without further survey it is not possible to give any reasons for the higher incidence of infection in Muzaffarpur where the inhabitants are better socially and there is very little overcrowding. As far as reliable history goes there have been 11 deaths from tuberculosis in this village within 10 years. Out of these 9 belonged to one family of weavers and two belonged to two different agriculturist families. Of the latter two, one was a case of Pott's disease in a young man of 20, and the other was a case of 'galloping' phthisis in a married woman aged 24, both seen and diagnosed by me on previous occasions.

The present history of these families is interesting. There are 8 surviving members of the weaver family and out of these 6, i.e. 75 per cent, are tuberculin-positive. All the members are weak and pale and two young men looked suspicious although physical examinations were negative. One girl aged 10 has phlyctenular conjunctivitis and gave ++++ reaction. The family of the girl who died from acute phthisis consists of 15 members. Out of these 14 were exposed to infection but there were only 6, i.e., 43 per cent, positive. The lower incidence of infection in this family may be due to much better social standard and also to the fact that this family lives in much bigger houses with spacious compounds and both men and women spend most of their days in the open fields.

In conclusion I must thank Dr. Munshi Singh, medical officer in charge Shanker dispensary, and Dr. Ram Rakha, medical officer in charge of the tuberculosis dispensary, Jullundur City, and the civil authorities for rendering me valuable assistance in this work. My thanks are also due to Dr. A. C. Ukil for help and advice in preparing this paper.

searabiasis or 'beetle-disease'. Cases in Ceylon and India* have been reported from time to time by a number of observers, Dey (1919, 1920), Sen (1924), Chakravarty (1919), Senior-White (1920), Senior-White and Sen (1921) and Iyengar (1928).

The belief that in such cases the beetles were passed with the faeces is founded on the report of the medical officers concerned with the clinical aspects of each case, but there is one record by Chakravarti of two live beetles having been passed after the administration of a salt-water enema, and Senior-White has stated that a compounder had told him of two beetles being found in the intestine at autopsy, no note unfortunately having been made as to the part of the intestine in which they were located. The reports in general state that the insects are passed at intervals which may extend over some months. These and other circumstances have led one to conclude that adult beetles live in the intestine of the patients.

Geographical distribution

The condition appears to occur in certain parts of Bengal, Assam, Burma, and Bihar (Ranchi), in South India, and Ceylon. The following is a summary of their species and distribution as recorded by previous observers:—

<i>Onthophagus</i>	Senior-White (1920)	Metale, Ceylon.
<i>unifasciatus</i> *	Iyengar (1928)	Ranchi, Bihar.
<i>Onthophagus</i>	Senior-White and	Bengal.
<i>bifasciatus</i> .	Sen (1921).	
	Iyengar (1928)	Bengal and Burma.
<i>Caccobius</i>	} Iyengar (1924 and 1928).	Faridpur, Bengal.
<i>mutans</i> .		
<i>Onthophagus</i>		
<i>bifasciatus</i> .		
<i>Onthophagus</i>	Sen (1924)	Faridpur, Bengal.
<i>bifasciatus</i> .		Akyab, Burma.

* Senior-White identified as *O. bifasciatus*, whereas Arrow considered the species *O. unifasciatus*.

We now add further notes regarding beetles that have been forwarded to us either in a dry state or in spirit by the medical officers concerned.

The infestation of the alimentary canal of children is perhaps more common than such records would lead one to believe; they apparently connote a rural disease, of which a relatively small proportion of cases have come to the notice of doctors.

One noticeable feature about the condition is the age-incidence: it has not been reported from sucklings and only once from an adult;

* de Meillon (1937) has reported it from South Africa.

only those who have cut their teeth and are able to take solid food have been affected.

teric symptoms. Progressive emaciation has been a marked sign and sometimes there are

* Associated with intestinal myiasis, *Sarcophaga ceylonensis* bred out.

Dr. Coltman's case was the only one which was much above the ordinary age, and it otherwise proved to be interesting. The patient was a wireless operator on a ship and had been admitted to hospital for bacillary dysentery. He there passed a large number of maggots which were brought to us in water and we were able to breed out only 2, which proved to be *Sarcophaga ceylonensis*; subsequently he passed others and though none from this batch could be reared in the laboratory, the characters of their posterior spiracles pointed to their also being larvæ of *Sarcophaga*. It was in the latter stool that a coprid of the genus *Saprinus* was found.

All previous observers have reported the occurrence of only one species of Coprid from the same patient, whereas it will now be seen that invasion by more than one species may take place in the same patient. Out of 6 beetles forwarded by Dr. Pillai from Travancore three species of *Coprinae* from one stool were encountered, and among Dr. Chatterjee's collections from Faridpur there were as many as 4 species in a single stool.

The passing of beetles in the stool naturally causes a great deal of alarm in a family, especially when it is attendant upon a long train of symptoms. The child has perhaps been in indifferent health, has lost his appetite and frequently had diarrhoea and occasionally dysen-

teric symptoms. He has usually been treated for his intestinal symptoms and the passing of an insect with the stool naturally causes great alarm. The stool is usually semi-solid, never hard, and after it has been voided, the attention of the mother may be attracted to some movement in it, a beetle gradually looms up to the surface, emerges and flies away. As a rule the infestation is by more than one beetle and sometimes large numbers are passed over a period of months, the health of the child improving in the intervals.

Habitat and life history

Very little is known of any of the above-named species, Arrow (1931) giving the following information:—

<i>Onthophagus bifasciatus</i>	A specimen found upon a dead rat by Dr. Gravely.
<i>Onthophagus unifasciatus</i>	Dr. Beeson has found this species on a dead lizard at Bangalore and it has also been seen in heaps of decaying grass-hoppers at Yammiganur: it is the species most commonly associated with scarabiasis.
<i>Onthophagus cervus</i>	One of the most abundant of Indian <i>Coprinae</i> .

The life-history of members of the sub-family *Coprinae* has an important bearing on their method of invasion of the victim and it may be assumed that all species are dung-rollers, their life-history differing only in small details.

As far as is known each egg is laid separately in carefully prepared chambers in a mass of dung with a store of food sufficient for the needs of the young insect during the whole period of immaturity and parasitism and as a rule it is not observed. The total number of eggs laid is as a rule small, in some cases as few as three or four and probably always less than a dozen: they hatch in a few days after their deposition. According to Lefroy the larval life of an Indian *Onthophagus* lasts about 21 days. The pupal stage is assumed inside the chamber and after about 4 weeks' interval the adult stage is attained, therefore the life-cycle from egg to adult covers a period of from 6 to 7 weeks.

Mechanism of infestation

How do the beetles obtain access into the human intestine?

Two hypotheses hold the field, that they gain entrance with the food, and that they enter by the anus.

It is quite possible that the invasion takes place through the mouth. Beetles during their early stages may be ingested accidentally with the food, when for instance young children eat food picked up from mud floors, as they often do. The mud floors of houses in East Bengal, where such cases commonly occur, are smeared every morning with a mixture of cowdung in water, but whether these species of beetle oviposit in cowdung is not known.

If the invasion takes place by the mouth, the eggs or later stage insects must be not only able to resist the action of the intestinal juices but also grow and develop to the adult stage in the alimentary canal. It is of course possible for an insect that habitually lives in aerobic surroundings to complete its life-cycle in an anaerobic medium, *Apiochæta ferruginea* being a good example.

Coleoptera are holometabolous insects and if the invasion takes place through the mouth, it should be possible to confirm it by making a very careful search for the early stages and finding the larval and pupal skins in the stool. We have had no opportunity so far of having a patient under our care in the hospital, and hence such an investigation has not been possible.

That the invasion takes place through the anus was first suggested by Senior-White and Sen (1921), and Fletcher (1924) thought the adult beetles, guided by a keen sense of smell in search for human ordure, effect an entrance *per anum* in children of the age of 2 to 5. The identification of the sex of the beetles that had been generally found in the stools is in favour of this suggestion, as all, except one, turned out to be of one-sex, which would not have been likely if the infestation had been derived *per os*.

However although the sex-ratio in all of our own collections was not ascertained, in one instance when 7 beetles were forwarded to us for examination, 6 males and 1 female, and in another, out of 9 specimens, 6 males and 3 females were recorded.

Iyengar also believes that the beetles effect an entry *per anum* while the child is asleep and not at the time of defæcation, as previously suggested by Senior-White and Sen (1921). In support of this hypothesis he has cited the instance of *Macropocopris*, which usually lives on the droppings of the wallaby in Australia. 'These beetles cling to the fur of the wallaby and as soon as the wallaby evacuates, they jump on to the droppings and live on them. This is their normal procedure but often enough it has been found that they effect an entry into the cloaca of the wallaby and live in its lower intestines'.

Children in rural India between the ages of 2 to 5 years usually visit a screened place adjacent to their dwelling and sit on the ground. The stool is seldom cleaned up at once: it may, however, be washed away or left to be eaten by jackals, dogs and other scavengers. When it is thus left for 3 or 4 days, many insects, especially beetles, take shelter under it and at the time of a child defæcating the beetles might enter the rectum through the anus.

The presence of more than one species in the excreta of the same patient perhaps connotes invasion by the anus.

On the other hand the freedom of helpless sucklings is against the hypothesis, as they particularly lie about on the floors and are often in such an unclean condition that they should be most attractive to the beetles.

Whether the infestation be *per os* or *per anum* it is difficult to explain how the patients continue to pass the insects for months on end even after the subjects have been removed to better sanitary surroundings.

Our thanks are due to Dr. G. Arrow of the British Museum and to Mr. Beeson of the Indian Forest Service for the trouble they have taken to identify the specimens forwarded to them.

A Mirror of Hospital Practice

APPLICATION OF VAUGHAN'S MODE OF DELIVERY, WHERE FORCEPS WERE DEFINITELY INDICATED*.

By MARY KEITH-THOMPSON, M.A., M.B. (Cal.),
F.R.C.S. (Ed.), L.M. (Coombe), D.T.M. & H. (Eng.)
New Delhi

The patient, 37 years of age, was a Brahmin. She had had one abortion and eight children, all are alive except the second, the last was delivered by me, about 4 years ago. I had seen the patient only once, when she was about 8½ months pregnant. The child was in the LOA position, with the head fairly small and easily pushed through the brim.

In August last, the husband informed me that his wife had influenza but that she did not need me to visit her.

About 8 p.m., on the 5th of September, the *dai* who was to assist me in the case, came and reported that the patient had been having slight labour pains, since early in the morning but that I need not go immediately. I suspected uterine inertia, and so left instantly. When I got there about 8-30 p.m., I saw that the patient had a definitely pendulous abdomen and was walking about in her room. She had taken a dose of castor oil at 6 p.m. and the pains were now coming more regularly and more strongly. She was also suffering from bronchitis, after the influenza, she had in August. About 9 p.m. she passed a loose motion followed by another in a short while.

On internal examination I found the os two fingers dilated, the head floating freely above the brim but the exact size of the head could not be gauged, because of the extreme thickness of the abdominal wall. Strong pains were now coming every 5 minutes but there seemed to be no progress at all, and the patient was becoming anxious and restless. At 11 p.m. I did another internal examination and found that the os had now dilated to 2½ fingers only. I doused the vagina with half an ounce of chloral hydrate mixed with two teaspoonfuls of boric acid in two pints of water, as hot as the patient could stand. A binder was next applied.

12 midnight.—The patient was becoming exhausted and begging of me to apply forceps but refused to have any anæsthetic.

12-25 a.m.—The os was fully dilated and the head apparently fixed, remained stationary even with the strong pains and seemed fixed behind the pubic rami.

12-30 a.m.—The membranes ruptured but still there was no progress of the head.

1 a.m.—The head was still in the former position. I was considering putting the patient in the Walcher's position and applying forceps but in this there were two difficulties—

(1) The patient objected to an anæsthetic.

(2) The bed was extremely low and neither bricks nor books were available to raise it.

Accordingly I decided to use Vaughan's method of delivery. After some difficulty the patient agreed and at 1-20 a.m. she was put in the squatting position.

1-25 a.m.—After only one strong pain, a portion of the head was showing, at the perineum. I then quickly put the patient lying on her back as usual, and took control of the perineum.

1-30 a.m.—The large head was delivered. As soon as the head was out, the pains ceased altogether, so the shoulders and the rest of the body had to be extracted manually.

2 a.m.—The pains fortunately started again and the placenta was expelled without any trouble. As usual, the patient was given a dram of liquid extract of ergot in water followed by injections of 1 c.cm. pituitrin extract and 10 c.cm. polyvalent puerperal anti-streptococcal serum and she was advised to take quinine and ergot mixture, from the next morning.

After some trouble in the puerperium the patient made a satisfactory recovery.

Remarks

1. The true conjugate, in Walcher's position it is said, is lengthened by half an inch; it would be interesting to find out exactly by how much it is increased in the squatting position.

2. Once the head has passed through the brim, the patient should be put back into the orthodox position and the perineum controlled, in the usual way, to prevent a rupture.

3. In all borderline cases and in those with slight disproportions, before the application of forceps, the patient may be put into this position.

4. As this seems rather an uncomfortable position at term, even for an Indian patient, I should adopt this mode of delivery, only in a case of difficult and prolonged labour.

DIPHTHERIA IN AN UNUSUAL LOCATION

By K. GHOSE, M.B.
Raniganj, E. I. Ry.

ON 28th October, 1938, I saw a girl, aged eight months. It was said to be the third day of her illness. Her upper lip was markedly swollen and everted, and on its inner surface there was an ulcer extending over almost the whole of its length and breadth. The ulcer was covered by what seemed to be a thick, white slough. At the centre of the lower lip, there was a small white patch, this lip was not swollen. The girl was running a temperature between 100.4°F. and 102°F., from the beginning of her illness. Moist sounds could be heard over both the lungs, especially over the left base. She was given prontisol album from that morning, besides local treatment. Exactly how the ulcer developed could not be learned from the parents; all that could be gathered was that it had begun as a tiny vesicle and assumed these proportions within three days.

By the evening of the next day the swelling of the upper lip appeared slightly less. The white slough had been removed by the patient's mother, leaving a raw surface. The lower lip was slightly swollen. Otherwise, there was no change.

* Abridged by the Editor.

On 30th October it was found that the upper lip was more swollen than on the previous day. The ulcer had extended beyond the angle of the mouth on either side, and the white slough had formed again. The white patch on the lower lip had increased in size and there was a similar patch on the tip of the tongue. The girl appeared fretful and resented being disturbed in any way. It was thought at this stage that the case might be one of diphtheria, and smears were taken from the ulcer that evening. The temperature, that night, shot up to 104.4°F.

The laboratory report, which was received next morning, confirmed the suspicion and accordingly 8,000 units of diphtheria antitoxin were injected intramuscularly. At the time of injection it was noticed that the swelling of the upper lip was less than on the previous day. The girl had a temperature of 102.4°F. in the morning, which rose to 104°F. at night. Protosil was discontinued from this day.

The next morning the swelling of the lips was much less and the temperature was 100°F. Another 8,000 units of the antitoxin was injected. In the evening the temperature rose to 103°F.

On the following day the swelling became still less and the temperature came down to 98°F., for the first time during the illness, in the morning, but rose to 101.4°F. in the evening.

No further injections were given. The ulcer healed gradually in the course of the following few days, and the girl made an uneventful recovery. The catarrh of the lungs persisted throughout. During the whole course of her illness the girl never showed signs of toxæmia and the throat did not show any detectable evidence of infection which, together with the unusual site of localization, is the main point of interest in this case.

I wish to thank Dr. S. K. Roy, bacteriologist, the Mines Board of Health Laboratory, Asansol, for the laboratory report.

AN INTERESTING CASE OF ASCITES*

By S. N. DATTA, L.M.P.

*Assistant Medical Officer, Bordubi Tea Estate,
Doom Dooma, Assam*

G., an Oriya female, aged 30 years, married, was admitted into the Bordubi Hospital on the 2nd November, 1938, with the complaint of fluid escaping through her umbilicus.

Condition on admission.—She was of medium build and height, poorly nourished. Hæmoglobin—55 per cent. There was an enlargement of abdomen due to a certain amount of fluid in it. Spleen—enlarged. Liver—normal. Heart sounds—nothing abnormal. Lungs—normal. Throat—normal. Urine: colour—yellow, specific gravity—1012. Reaction—acid and no abnormal constituents. Albumin present in escaping fluid.

Stools—no helminthic nor protozoal infection.

The umbilicus was hard with a prominent lump. No œdema. No umbilical hernia. Temperature—97.4°F. Pulse—76 per minute. Respiration—16 per minute.

Previous history.—She had one abortion in 1936. In 1938 she gave birth to a premature male child which died after a day. On both these occasions she was anæmic with some amount of œdema of her extremities. Two days prior to her admission, on the 31st October,

1938, afternoon while she was lifting a medium-sized bucket full of water, she noticed some fluid gushing out through her umbilicus, and she collected the fluid in the bucket in which she carried water. The fluid ceased flowing after the bucket was three-fourths full. A slight amount of fluid dribbled all the time while she was in hospital. She took it to be a pregnancy as she had had no periods since she noticed the gradual enlargement of her abdomen, i.e., for about six months.

Her friends remarked that some one had bewitched her and converted her pregnancy to water. She went back to her house and applied some indigenous preparation to her umbilicus to stop the oozing. She was doing her household work without any trouble whatsoever.

On hearing the history of the case from the line compounder, I wanted to bring her into the hospital next morning, but she said, 'I am better now and will go to the office this afternoon to report the name of the wizard to the manager, then afterwards I will come to the hospital'. She came to the hospital on the morning of the third day with some enlargement of the abdomen, and on slight pressure the fluid came out through the umbilicus.

The ascites was obviously not due to cardiac or renal disease, as no signs of such disease were present. Tuberculous peritonitis was also improbable, because there was no pyrexia, emaciation, nor enlarged glands in the abdomen. Malignant disease was not possible, there being no enlargement of liver, no jaundice, no emaciation and no signs suggestive of disease in the intestine or in the pelvis. Cirrhosis of the liver, and anæmia (hæmoglobin was 55 per cent) were the other possibilities.

Treatment.—The patient was treated as a bed case and E. C. (electrolytic chlorine solution) dressings were applied over the umbilicus and firmly bandaged. She was put on a mixture containing ammonium chloride gr. xv and calcium chloride gr. xx, three times daily. She was also given iron, arsenic and cod-liver oil as tonics. There was no obvious improvement with this treatment. She was next given two injections of salyrgan every three days. This led to marked improvement and the abdomen became almost normal. She was also given four injections of N.A.B. A similar course was given after her abortion in 1936. The oil morrhue was prescribed for her poor health and general debility. She was discharged on 18th November, 1938, from the hospital after a fortnight as cured.

Points of interest

(i) The rare occurrence of fluid escaping suddenly through the umbilicus.

(ii) Complete lack of any distress or discomfort throughout the illness.

(iii) Six months' amenorrhœa with gradual enlargement of abdomen simulating pregnancy.

(iv) No presumptive signs of specific disease have been observed except for the history of one abortion and one premature birth at 8 months.

(v) Was the subsidence of the ascites due to the two injections of salyrgan or to subsequent exhibition of N.A.B.?

Acknowledgments.—My grateful thanks are due to my chief Dr. D. M. Bertram, for his valuable advice and kind permission to read this note, and also to Mr. R. A. Crampton, Superintendent of the garden, for his keen interest in this case and all hospital affairs.

*Being a paper read at a meeting of the Assam Frontier Budla Beta Medical Society held on 6th May, 1939, at Doom Dooma Club.

Indian Medical Gazette

JULY

LATHYRISM

It is an everyday experience to encounter victims of lathyrism in the streets of Calcutta. These people usually come from North Bihar or the United Provinces and are beggars by occupation. Most of them have been cultivators or labourers, and the usual account they give of the onset of their disability is that during some years of scarcity they had to live mainly on chick peas and that the disease then began, insidiously in some cases, suddenly in others. The disability gradually increased until they could walk only with the help of sticks, their legs stiff, weak and trembling and their gait spastic and scissors-like. In advanced cases progression is effected by crawling on the balls of the feet and on the hands.

Lathyrism was first recognised in Europe over two hundred and fifty years ago, and it is obvious that even in those early and unscientific times it was ascribed to the ingestion of the seeds of various species of the genus *Lathyrus*, because as early as 1671 the Duke of Württemberg issued an edict forbidding the use of these seeds. Later, it was observed in Italy, France, Algeria and certain eastern countries. It is now rarely seen in Europe and the chief interest in this disease at present centres in India where it is shown to have been prevalent for at least as long as written records of Indian history exist and where it is still one of the most important causes of paralysis and deformity among the poorer sections of the population in certain parts of the country. During the last hundred years it has been frequently reported upon by writers on medical matters of local interest and importance, and a great deal of the most recent research on the still-disputed aetiology of lathyrism has emanated from workers in India.

The disease is regarded as a form of food poisoning by most authorities and, as the name implies, substances in the seeds of the genus *Lathyrus* have usually been considered to be its cause. In India, the species held responsible is *Lathyrus sativus*. Stockman and Dilling both lent support to this theory because they independently isolated from the seeds of this plant alkaloidal substances which when inoculated into animals produced symptoms suggestive of lathyrism. Acton and Chopra also held the opinion that the seeds of *L. sativus* contained a toxic substance, but the toxin they isolated, and which caused lathyrism-like signs in monkeys and ducks, was a water-soluble amine. So that, although these workers are all in agreement as to the seeds being the cause, they are at variance

as to the actual offending substance. Further evidence adduced by still other workers, as a result of animal experiments, are also conflicting, probably because samples of seeds of *L. sativus* are very frequently contaminated by seeds of various unidentified weeds, which most likely play some part in the production of these varying results recorded. Howard, Simonsen and Anderson showed that botanically pure lathyrus seeds could not produce any toxic effect, but a contaminant of the lathyrus seed, *Vicia sativa* (*akta*), contained bases having alkaloidal properties, which produced definite signs of poisoning with involvement of the central nervous system in laboratory animals such as guinea-pigs. McCombie Young was of the opinion that deficiency of vitamins, particularly vitamin A, was a factor in the production of the disease. Stockman later reported that watery extract of lathyrus contained a salt of phytic acid which was toxic to the brain and spinal cord. Stott could not reproduce the symptoms in horses by feeding them on *L. sativus* or *V. sativa*.

The above brief outline shows that there are two main views regarding the causation of the disease, viz, (a) that it is due to food intoxication, either by *Lathyrus sativus* or by *Vicia sativa* and (b) that it may be to some extent a deficiency disease.

In this issue of the journal there is a paper setting forth the details of an outbreak of lathyrism in a Punjab village, this village is in an area where there have never been cases of lathyrism before. The paper brings out several features of interest. The disease affected the Sikh agriculturists mainly, and three males to every two females suffered. The pea *Lathyrus sativus* was definitely not the cause of the disease, as this was not cultivated in the locality, nor did it occur as a contaminant of other cereals. It was finally found to be caused by ingestion of flour made from wheat that contained seeds of *Vicia sativa*. This vetch seems to have occurred as a weed in the wheat fields and was harvested along with the wheat. Inspection of the wheat showed the presence of these seeds and the identification of them as *V. sativa* was definitely established, as plants grown from the seeds were found to be the same specimens as of *V. sativa* plants supplied by a botanist.

The symptoms of the disease became aggravated whenever the people took bread made from the old stock of wheat that was contaminated with vicia seeds; wheat from other sources had no such effect. These findings have lent support to the *V. sativa* (*akta*) contamination theory of Howard, Simonsen and Anderson and has ruled out the possibility of *L. sativus* being the noxious agent. Avitaminosis cannot be dismissed completely as a possibility in view of the poverty of the people, but avitaminosis, if present, must have been there for years while the epidemic of lathyrism followed the harvesting of the wheat crop contaminated with *V. sativa* seeds.

in. Keep the patient in bed or at least flat on his back with knees raised at right angles to the body and head at a lower level than the body. Cover the patient with blankets, give hot water bottles, massage the limbs and apply binders on the limbs from below upwards towards the abdomen, in order to confine the circulation as far as possible to the brain and medulla. Further treatment may be given to the wound and for the respiratory and circulatory failure and collapse.

(a) *The wound*.—Before the actual treatment of the wound is begun, efforts should be made, if possible, to identify the type of snake. The seriousness of the condition and the prognosis depend upon the following points:—*The dose of the venom injected*. It depends upon the size of the reptile and the season of the year. Usually the dose injected is large during the rainy and summer months when the snake is full of vigour and is in search of food. The dose may be expected to be smaller during winter months. (2) *The site of the bite*. The venom will produce more toxic effects if the bitten area is vascular, e.g., back, abdomen, chest, face and proximal portions of the limbs, and if the wound is very deep. The danger is less when the bitten part is less vascular as in the case of fingers, toes, hands, feet and forelimbs. (3) *The age of the person bitten*. This is also important, as children and old people have much less resistance than adult and vigorous people. Children succumb more quickly because they have a far smaller volume of blood in proportion to the body surface. The mental condition of the patient has also a good deal to do with the onset of symptoms. A woman or a neurotic individual will collapse sooner than an adult or a courageous man. Lastly, the treatment also depends upon the time that has elapsed between the infliction of the wound and the availability of medical aid and the depth of the venom intoxication.

In a previous paper the present authors have reviewed the treatments of snake bite in vogue. All these aim at the prevention of absorption of the venom into the general circulation by fixing it locally at the site of the bite, by coagulating and oxidising substances such as injections of potassium permanganate (2 to 5 per cent solution) or gold chloride (1 to 2 per cent), palladium dihydrochloride, hydrogen peroxide, calcium chloride (2 per cent) or cauterization of the wound. The venom may be drained out of the wound by different mechanical and surgical means such as incision, cupping or suction and squeezing out of the wound or by venesection.

The indications and uses of specific polyvalent antivenene as a specific remedy have also been discussed in detail. There is a long list of indigenous remedies said to be specific against snake bite. We have had occasion lately to test a good number of these remedies but none of them were found efficacious in experimental animals in whom a certain lethal dose of cobra

or viper venom was injected. Mhaskar and Caius (1931) mention no less than 300 indigenous plant remedies reputed as snake-bite cures but none of them were effective. Lauder Brunton introduced a lancet with a container for potassium permanganate to be used in emergency cases of snake bite. It was found to be very useful for workers in the field. Recently a cheap and compact 'Asepto' snake-bite suction outfit has been put on the market by Becton, Dickinson and Co., Rutherford, N.J. It consists of a safety razor blade for quick incision of the bitten area, two small tubes of Ioply (Iodine solution in proportion of 3.5 gm. in 100 c.cm. of 50 per cent alcohol), a strong suction bulb, and a rubber band to be used as a tourniquet. All these are put up in a strong metal tube 2 × 4 inches that can be easily carried in the pocket. Whatever treatment is to be applied, the initial local incision, suction and application of a coagulant into the wound to fix the venom locally is very essential, and hence this compact suction outfit will be found very useful for people in the field when other drugs and specific antivenene are not readily available.

In the introduction to this paper we said that it is only 20 to 25 per cent of the victims who really require specific treatment or drastic surgical measures. In the balance, the bite may be from non-poisonous snakes or the patient may have only received a sub-lethal dose of the venom. In almost all the cases, therefore, particular attention should be paid to preventing the 'fear collapse' and the actual shock due to absorption of the venom into the general circulation. Attention to this may save a large number of the victims and may at least give time for application of the specific remedy in the really serious cases. The management of such sequelæ as respiratory failure and circulatory failure from 'fear shock' is important and urgent and we propose to discuss it in detail.

(b) *Respiratory disturbances*.—These are more manifest with colubrine bites. The cobra and krait venoms have a particularly marked effect on the respiratory and later on the vasomotor centres. There is slight stimulation of these centres at first, followed by paralysis giving rise to a shallow and rapid respiration, which later becomes diaphragmatic in type and may end in asphyxia and convulsions.

The heart seems not to be much affected and continues to beat for a much longer time, even after cessation of respiration. Kellaway, Cherry and William (1932) showed that almost all the Australian snake venoms including Indian Colubrids (*Naia Naia* and *Naia hannah*) and the dreaded sea snake (*Enhydrina schistosa*) cause death by peripheral action. The phrenic nerve in the neck was placed over electrodes connected to an amplifier and a loud speaker. Different venoms were injected intravenously in divided doses and in big doses, to cause failure of the respiratory movements. When respiration became asphyxial in type artificial respiration

was started. The strong action-currents generated in the centre and travelling downwards were heard through the loud speaker. After injections of cobra venom the action-currents were heard, these increased when artificial respiration was reduced and decreased when the artificial respiration was increased. It was further seen that the nuclei of the respiratory centre in the medulla were not very much affected and could be revived if artificial respiration was continued for a length of time sufficient to oxygenate the blood. These experiments show that artificial respiration should be started at once and should be kept going as long as the heart is beating or as long as the least signs of life are present. Oxygen, carbon dioxide or both together may be tried. Artificial respiration specially with a gas mixture containing 5 to 10 per cent of CO_2 is highly effective as a single resuscitation measure. The best practical method of administering CO_2 is to ask the patient to breathe through a mask or through a rubber bag again and again. In this way the person breathes his own expired air repeatedly and thus the CO_2 intake is increased. Dilatation of the rectum with the fingers is also a good emergency measure for stimulating the respiration. Strychnine and cardiazol are worth trying in cases of respiratory failure. Koll (1937) has reported that cardiazol (metrazol) and strychnine have a marked restorative effect and completely antagonize the effects of narcotics on the higher centres. In narcosis the reflex synaptic field is very much affected. Cardiazol and strychnine reinforce one another to improve the synaptic union of the reflex arcs. Cardiazol has the additional advantage of combining the properties of a respiratory stimulant with those of a cardiac and circulatory tonic. As much as 5 to 10 c.cm. of a 10 per cent solution can be given intravenously or intramuscularly without any ill effects. Becmann (Knoll, 1938) recommended intravenous injections of 1 c.cm. of cardiazol ephedrine in cases of snake bite. Morawitz (Knoll, 1938) and Lesche recommended this drug in cases of viper bites as well. We consider that cardiazol-ephedrine may be recommended as first aid in all cases where respiratory disturbances are apprehended. Vellard (1929) in his experiments on animals, regarding the use of specific drugs as an auxiliary treatment of snake bite, reported that sparteine in 15 mgm. doses completely protected against the venom of *Crotalus terrificus* and alleviated the symptoms caused by cobra venom. Strychnine (0.04 mgm.) protected against lachesis and jararaca; adrenaline (0.05 mgm.) protected against lachesis, jararaca and cobra venom and alleviated the symptoms of *C. terrificus*; pilocarpine (20 mgm.) completely protected against cobra venom; caffeine (20 mgm.) protected against jararaca and cobra venoms. Similarly, magnesium chloride completely protected against cobra venom. Morphine, cocaine, atropine, digitaline and camphor-in-oil and alcohol had no

protective action at all. It is quite likely that the above drugs may have some value in the treatment of snake bite. Coramine in 25 per cent solution may also be used orally or hypodermically. In serious cases 5 to 15 c.cm. of this drug, intravenously, stimulate the vital centres. It is therefore a cardiac and a respiratory stimulant and has proved of marked value as a restorative in collapse and asphyxia due to narcotic drugs and poisoning, as in snake bite and electrocution accidents. Icoral, a mixture of coramine and ephedrine derivatives, is marketed as a remedy against shock and anaesthesia accidents. It has a marked stimulant action on the medullary centres and therefore may be useful against colubrine poisoning. Barlow (1935), while discussing the use of respiratory stimulants so far used, mentioned lobeline, strychnine, picrotoxin, caffeine, cocaine, camphor (including coramine, cardiazol and hexatone) and ephedrine and suggested that there is no unanimity of opinion with regard to their value as analeptics. Judging their usefulness by the degree of improvement in respiration, circulation and reflex excitability, and hastening of recovery, drugs and measures in order of their effectiveness are picrotoxin, cardiazol, ephedrine, artificial respiration, coramine, icoral, strychnine and caffeine sodiobenzoate. The respiratory stimulant effects of cardiazol exceed those of any other preparation tested by him both as regards the speed and degree of action. Improvement in circulation is often the result of improvement in respiration. Excessive doses of cardiazol are liable to produce convulsions. Ephedrine and icoral may be used with good effect.

In a series of cats we gave toxic doses of cobra venom, and when the fall of blood pressure and respiratory irregularity developed, cardiazol was administered intravenously without supplementary artificial respiration. In some cases cardiazol-ephedrine combination was used in place of cardiazol alone. It was observed that this combination restored the respiration and blood pressure more promptly than artificial respiration alone. In intact animals when a state of coma and respiratory difficulty was produced with cobra venom, cardiazol-ephedrine injection and artificial respiration restored the animal to a great extent. We are of opinion that these drugs administered in addition to antivenene in cases of emergency may act as good restoratives, and if specific antivenene is not available these remedies may be of value in saving life in a certain number of cases.

(c) *Circulatory failure.*—Cobra venom acts primarily on the respiratory system, the heart and the circulatory system being affected in later stages. With fatal doses its action on the heart is similar to that of digitalis poisoning. Gunn and Epstein (1933) have reported that the action of the 'black neck' and cape-cobra on the toad's heart is more or less like that of digitoxin and not like that of sapotoxin. Toxic

from losing consciousness and getting into a state of collapse in a short time.

(d) *Hæmorrhages*.—Extensive bleeding occurs usually in the case of viper bite. In early cases the hæmorrhage occurs only at the site of the bite, in the form of constant oozing of the blood from the fang punctures. This symptom itself is of diagnostic importance in distinguishing between a colubrine and viperine bite. Later, the bleeding occurs in the form of petechial spots under the skin, the beds of the nails and in the submucosa, e.g., from the nose and eyes, and in form of hæmoptysis and hæmatemesis. Even instances of bleeding per urethram and per vaginam have been observed. These hæmorrhages occur as late symptoms in viper bites. Often the blood becomes so poor in its coagulation power that it becomes very difficult to prevent these constant internal hæmorrhages. A few years ago advice was sought from us by telegram with regard to a person who was bitten by a viper more than two weeks earlier. The bleeding commenced about ten days after the bite and all remedies had failed to stop it. Therefore if a case is bitten by a viper, in addition to other treatment, coagulants should be given to prevent this complication. Calcium lactate by the mouth or intravenous injection of calcium chloride is often very useful. Other drugs such as coagulin (Ciba), hæmoplastin (P. D. & Co.), and Congo red 10 c.cm. of a 5 to 10 per cent solution intravenously may be tried. Injections of normal horse serum are useful. Mixed antivenene in doses of 40 to 60 c.cm. has often been found to act as a good hæmostatic. Stockton and Franklin (1931) used antivenene in cases of purpura and uterine hæmorrhages. Vitamin C in doses of 0.05 to 0.1 gm. intravenously may be given daily or on alternate days. In viper bite, bleeding is due to the damage of the endothelial cell lining of the terminal blood vessels in the sub-cutaneous and sub-mucous tissues. Vitamin C strengthens and restores the tone of these damaged cells and so prevents the leakage of the blood from this source. Sajidiman (1937) reported that in a case of bite from *Bungarus fasciatus* there was occurrence of hæmorrhage from all parts of the body, delay in coagulation time, prolongation of bleeding time, severe thrombocytopœnia, increased sedimentation rate and great tendency to œdema. He injected vitamin C (Redoxon) on the ground that it possesses styptic property, promotes and increases the number of thrombocytes and probably also the serum albumin. There is no doubt that after vitamin C injections there was a striking increase in the thrombocytes. The patient recovered and, except for persistence of infiltration of the bitten leg and some local pain, other symptoms disappeared.

Discussion and conclusions

We have stated that out of 110 varieties of snakes existing in India, only 69 are poisonous

and out of these only 40 (39 per cent) are poisonous land snakes. In other words, it may be concluded in general that out of the 100 bites excluding sea snakes, there may be only 40 to 50 per cent bites by poisonous land snakes. Of the bites from these poisonous snakes some may be non-lethal from various reasons. Therefore only in 20 to 25 per cent of all the bites are the victims in real danger and for these unfortunate individuals it may not be possible to do much since the specific drugs and expert medical aid is not always readily available in out-of-the-way places where such accidents usually occur. Of the bitten, 80 per cent who have received non-lethal doses of snake venom or are bitten by non-poisonous snakes, many suffer from severe shock due to fear of impending death. Assurance to them in addition to immediate symptomatic treatment will save many who would otherwise die, probably of 'fear-shock' instead of real venom poisoning. In addition to the specific remedies such as intravenous polyvalent antivenene, the use of other measures such as ligature, incision, venesection, local use of potassium permanganate, gold chloride, etc., the patient may be saved if the other serious complications that occur after the bite can be treated. In the case of cobra bites the venom effects the respiratory centre particularly, in addition to its effects on the other centres in the brain. Cardiazol, ephedrine and veritol have been reported to be useful in counteracting the respiratory failure and have a stimulating effect in narcotic poisoning. These are therefore indicated in cobra poisoning. Artificial respiration and inhalation of CO₂ should also be employed to stimulate the respiratory centre. In the case of viper poisoning there is fall of blood pressure from acute dilatation and later paralysis of blood vessels, particularly of the splachnic area. Drugs such as pituitrin and veritol have been shown to contract such organs as the spleen, liver, intestines and push the blood into the general circulation. Veritol has the advantage as it pushes out the blood and unlike adrenaline it does not constrict the blood vessels and in this way increase the peripheral resistance. These drugs along with perfusion of physiological saline with gum acacia and glucose have been experimentally shown to revive animals in a condition of collapse and may be useful in human beings as well. For subsequent hæmorrhages intravenous injections of calcium chloride, Congo red, normal horse serum, coagulin and vitamin C are worth trying.

A FEW POINTS IN THE CLASSIFICATION AND IDENTIFICATION OF POISONOUS AND NON-POISONOUS SNAKES IN INDIA

Zoologists and medical men have attempted to provide intelligible guides to enable lay people to distinguish at sight the poisonous from non-poisonous snakes. Amongst the commonest species met with in the Indian Empire may be

mentioned the carpet-snake (*Lycodon aulicus*), the rat-snake or dhaman (*Ptyas mucosus*), the grass and the water snakes (*Rhabdophis stolicus* and *Nerodia*), the tree or whip-snake (*Dryophis nigriventris*), the cobra (*Naia naia*), the krait (*Bungarus candidus*) and the deadly Russell's viper (*Viper russelli*). The sea-snakes (*Hydrophynæ*) with a strong compressed, ear-shaped tail are also common on the Indian coasts, the most widely distributed being *Hydruis platurus* and *Enhydrine valakadieu*. The latter is known to be the most poisonous of all Indian snakes. There are other snakes not so well known but which, nevertheless, deserve mention. The burrowing 'earth-snakes' (*Uroplutidae*) are peculiar to the hilly tracts of peninsular India and Ceylon, while the small worm-like subterranean snake (*Typhlops*) is widely distributed all over the Indian Empire. Of the latter (*Typhlops braminus*) is the commonest. The best known python or rock-snake of India is *Python molurus*. The so-called double-headed snake kept by snake charmers in this country is *Eryx jaculus* which lives in sandy tracts of Southern and N. W. India. *Cerberus rynchops* lives in mud on the banks of large rivers and estuaries of the Indian region and feeds on fish. The raj-samp or banded kraits (*Bungarus candidus*) of North India are common all over the country and are very destructive to life. The king cobra (*Naia hannah*) is confined to parts of south and eastern India, Burma, and the Andamans, is of fierce and aggressive habits and feeds on other snakes. *Echis carinata*, another fierce snake of the viper class, is to be met with in the desert sandy tracts of India. The pit-vipers are represented in India by two species only, e.g., *Ancistrodon himalayensis* common in N. W. Himalayas and Assam and *A. hypnale* in Ceylon and Western Ghats.

There is no golden rule for identification of the poisonous or harmless snakes save examination of teeth and the head shields, a procedure that is seldom practicable for lay people.

To meet this requirement, various criteria have been proposed by specialists, none of which, however, is satisfactory.

There are snakes of striking resemblance but absolutely of different affinities, e.g.

- A. 1. *Echis carinata* (poisonous).
2. *Dispsadomorphus trigonatus* (non-poisonous).
- B. 1. *Bungarus caeruleus* (poisonous).
2. *Lycodon aulicus* (non-poisonous).
- C. 1. *Bungarus fasciatus* (poisonous).
2. *Hydrophotus davisoni* (non-poisonous).

In short, nothing but an examination of the dentition can afford positive information as to the poisonous or non-poisonous nature of an unknown snake.

In a previous paper (1935) the present authors described the classification of snakes as given

by Wall and the identification marks as described by him. The quick and easy way of classifying a snake is as follows:—(a) Lay the snake on its back and look at the scales on its abdomen. If the ventral scales are large and run right across the abdomen so that no dorsal scales are visible on either side of the abdomen, the snake is most probably poisonous. (b) Lay the snake on its abdomen and look on its dorsal surface. If the head is long and triangular in shape and is distinctly marked off from the body by a constricted neck and if the scales on the head are of the same size as those on the back, the snake is a viper. The head looks almost like that of a lizard. (c) Some vipers have a small depression situated between the eyes and the nose (loreal pit). These are known as *pit vipers*. Of the pit-less vipers the varieties commonly met with are *Echis carinatus* (Indian Phooras) and Russell's viper (Indian Daboia). The former has imbricated or saw-shaped scales on its body and has a bird's foot-print or broad arrow mark on its head and two rows of dark-coloured wavy bands running longitudinally along its back. In the case of Russell's viper there are three rows of circular or oval rings on its body. These rings vary in size and colour. All the vipers are poisonous to man. (d) If the scales on the head are broad, unequal, and larger than those on the body and look like shields, then the specimen is either a coral snake, a cobra or a krait. In the case of a cobra the neck is expandable in the form of a hood and may have a single ring mark (monocellate) or a double ring in the form of spectacle (binocellate) or there may be some black spots on the internal surface of the hood. The third supralabial scale touches both the eye and the nostril. This is an important diagnostic feature in a cobra. (e) The krait has only four submaxillary scales of which the fourth is the largest in size. The spinal scales, i.e., those situated on the vertebral column, are hexagonal in shape and larger than other scales on the back. There may also be transverse bands of different colours on the body.

These are a few of the distinctive features by which a poisonous snake may easily be identified. (In case of emergency this much is enough to differentiate a poisonous from a non-poisonous snake.) For the detailed study on the classification of snakes more elaborate works on the subject must be consulted. For ready reference Gharpurey (1935) has tabulated the classification of snakes as given below:—

In addition to the above scheme a few more points are given for confirmatory identification of poisonous snakes. It is not easy to make out all the points which are given below in small-sized reptiles or in snakes which have been badly bruised or crushed or have been macerated before they reach an expert for opinion. Still, before any opinion is given as many points as possible must be looked for.

TABLE
(Modified after Gharpurey's table)
Snakes.

Tail compressed side ways and flat. (Sea snakes, poisonous.)		Tail cylindrical and not compressed. (Land snakes, poisonous and non-poisonous.)	
Small scales on the abdomen as well as on the back. (Non-poisonous.)		Abdominal scales not extending right across it. (Non-poisonous.)	
Small scales on the head. (Non-pit vipers, poisonous.)		Abdominal scales covering the entire width of the abdomen. (Poisonous and non-poisonous.)	
Two rows of wavy bands on back, Government arrow mark on head. (Echis carinatus.)		Small scales on the head, a loreal pit between the nose and the eye. Pit-viper. (Poisonous.) { Ancistrodon himalayanus. } { Ancistrodon hypnale. }	
Third supra-labial touches the eye and the nostril. Cobras and coral snakes. (Poisonous.)		Shields on the head. Cobras and kraits. (Poisonous.)	
Neck with hood and markings. Cobras.		Scales in the central row on the back are enlarged and hexagonal and coloured bands or half rings across the back. Subcaudals undivided. Only four infra-labial scales, and the fourth is the largest. Krait. (Poisonous.)	
None of the characteristics mentioned in no. 1 or 2. (Non-poisonous.)		None of the characteristics mentioned in no. 1 or 2. (Non-poisonous.)	
With coral coloured spots near the vent. Coral snakes.		Three rows of oval spots on back. Russell viper.	

The colour and scales

The coloration of snakes is not always diagnostic. Although many snakes have definite colour and characteristic marks on their bodies, it is not possible to differentiate a poisonous from a non-poisonous snake by these characters alone. It may be mentioned that coral snakes and kraits have bright-coloured transverse bands on the body; Russell's vipers have about three rows of black and brown rings, and *Echis carinatus* show two dark wavy bands on the backs. Many of the non-poisonous snakes such as grass snakes, tree snakes and bamboo snakes have beautiful colour patterns on their bodies and have a long thin whip-like tail. Usually a snake with vivid colour-markings is popularly considered as dangerous and poisonous but this is not always so. Snakes generally change their colour according to the season, their age and surroundings.

Scales.—The body of all snakes is covered with scales. The scales on the back are usually quadrilateral in shape and are called 'costals' and those along the vertebral column the 'vertebrals' or 'spinals'. The scales on the abdomen are called the 'ventrals'. These ventral scales are usually broad and help in forward movement. The dorsal and ventral scales are similar in size and shape in the case of harmless blind snakes and burrowing snakes. The vertebral scales in the krait are hexagonal in shape and larger than the rest of the dorsals. The ventral scales stretch right across the abdomen in the case of poisonous snakes and in non-poisonous snakes they are small and do not stretch across, but are restricted only to the middle of the abdomen. The scales on the head are also characteristic in poisonous snakes. They are large, glossy and the shape of a shield in the case of cobras. The third supra-labial scale touches both the nostril and the eye in the case of cobras and the coral snakes. Similarly the submaxillary scales are characteristic in kraits, there being only four submaxillary scales of which the fourth is the largest.

In *Echis carinatus* the dorsal scales are rough and imbricated. In pit vipers there is a depression situated between the nose and the eyes called a *loreal pit*. This depression is a rudimentary homologue of the tear sac in mammalia.

Tail.—It is usually flattened and compressed laterally like an oar in the case of sea snakes and is round in land snakes. The tail is usually blunt and ends abruptly beyond the vent in vipers. The scales on the under surface of the tail are usually divided beyond the cloaca in the case of a cobra, but entire in the case of a krait.

Head.—In vipers the head is triangular in shape and is marked off from the body by a constricted neck. The scales on the head are similar to those on the body, the eyes are small and the pupils elliptical. In the case of cobras and kraits there is usually a mental groove beneath the chin. There is a distinct expansile

hood with or without single ring (monocle) or double ring (spectacle) on the back and dark patches on the under surface of the hood. In the case of *Echis carinatus* there is a bird footprint or broad arrow mark on the head.

Fangs.—In the case of poisonous snakes the maxillary teeth are enlarged and are called fangs. These fangs may be placed in the front of the upper jaw (*proteroglypha*) or at the back of the upper jaw (*opisthoglypha*). Snakes with fangs in the front part of the jaw are poisonous to man. These fangs sometimes measure $\frac{1}{2}$ to $\frac{3}{4}$ inch in length and are either grooved or canalized.

Vipers usually have very large fangs. If a pin is passed along the upper jaw, it is caught against the maxillary teeth, in the case of non-poisonous snakes. In the case of poisonous snakes no teeth are felt behind the fangs. In this way it is quite easy to locate the fangs in a living snake or even in a snake whose body has been badly crushed.

If the snake has not been caught or killed it may be sometimes necessary to determine whether the bite is from a poisonous or non-poisonous snake or if the bite was from a poisonous colubrine or a viperine snake. There are one or two deep punctures or scratches on the skin in the case of a bite from a poisonous snake; and there may be rapidly developing swelling and distinct oozing of the blood at the site of the puncture.

If the snake has been caught and there be still difficulty in identifying it, the authors will be glad to help in the identification of such specimens. The snake may be put in a wide-mouthed bottle and packed in methylated spirit or in 10 per cent formalin and despatched to them as soon as possible. The snakes may also be sent to Bombay Natural History Society, 6, Apollo Street, Bombay, or to the Zoological Survey of India, Chowringhee, Calcutta, for identification.

Medical News

THE ROCKEFELLER FOUNDATION. REVIEW OF WORK IN 1938

THE YEAR IN BRIEF

DURING 1938 The Rockefeller Foundation appropriated a total sum of over \$15,000,000. Of this amount, speaking in terms of rough classifications, \$3,800,000 was given to the medical sciences, \$3,800,000 to the social sciences, \$3,000,000 to the natural sciences, \$2,500,000 to public health, \$1,000,000 to the humanities and \$300,000 to rural reconstruction in China.

The Foundation's income during 1938 amounted approximately to \$7,000,000. In appropriating \$15,000,000 it was necessary, therefore, not only to use up the balance carried over from earlier years, but to dip into the principal fund to the extent of \$3,755,000.

In carrying out its 1938 programme the Foundation operated in forty-two countries in all parts of the world. Eighteen of these countries were in Europe, five in Asia, two in Africa, five in South America, ten in North and Central America and the West Indies, and two were islands of the Pacific.

Twenty-five per cent of the money given went to foreign countries, and the remainder, 75 per cent was for work in the United States.

To the China Medical Board; the Foundation gave \$1,580,000, under an earlier authorization, for expenditure over a period of approximately four years. Previously the Foundation had made annual appropriations to this Board toward the maintenance of the Peiping Union Medical College. Support over a relatively long period has now been given to enable both the Board and the College to plan with reasonable assurance for the immediate future.

To the American University of Beirut, the Foundation appropriated \$1,000,000 toward the endowment of its medical school, including nursing and premedical subjects. This action has been in contemplation for a number of years, and it is now believed that the University is in a position to raise the supplementary sums required and thus make a substantial addition to its resources.

Preventive medicine is then discussed in greater detail. Social insurance is treated in a special chapter and notes presented on nutrition, physical training, rural planning, and the education of rural populations in health matters. Another chapter is devoted to 'the training of doctors and their assistants in preventive and social action'.

Dr. J. de Barros Barreto, Director-General of Health in Brazil, draws attention to conditions in South American countries in discussing curative medicine in rural areas. In this article Dr. Barreto expounds the organization of medical care in all its aspects and examines in turn the financing of such a scheme, the establishment of a network of hospitals in large thinly-populated regions, the creation of dispensaries and the provision of drugs. He concludes with an examination of the much-canvassed problem of a State Medical Service.

The International Lists of Causes of Death adopted by the fifth International Conference on Revision, which sat in Paris from 3rd to 7th October, 1938, are also published in this number of the *Bulletin*. This conference resulted in the signature of a Convention recommending to Governments, as from 1st January, 1940, the adoption of three revised international lists: detailed (200 headings), intermediate (87 headings), and abridged (44 headings).

The Present Use of Naturalistic Measures in the Control of Malaria by L. W. Hackett, P. F. Russell, J. W. Scharff and R. S. White, is the title of the *Bulletin's* final article.

In including this problem, the malaria commission of the League of Nations had in mind the questions raised by rural malaria in poor countries. The article deals with the first step towards the solution of the problem by critically surveying all action taken so far on naturalistic lines. This is defined as 'the deliberate extension or intensification of natural processes which tend to limit the production of mosquitoes or their contact with man'. The authors stress the desirability of creating experimental centres and of ascertaining the cost of methods before applying them.

BULLETIN OF THE HEALTH ORGANIZATION, VOL. VII, NO. 6

THE latest issue of the *Bulletin of the Health Organization* is mainly devoted to rural life problems.

The League of Nations is at present engaged in preparations for the technical discussions of the forthcoming European Conference on Rural Life on questions of medico-social policy. For this purpose the Health Organization has prepared a technical document, *General Survey of Medico-Social Policy in Rural Areas*, which begins with an examination of the part played by curative medicine in rural areas.

GUIDING PRINCIPLES FOR STUDIES ON THE NUTRITION OF POPULATIONS

THE Health Organization of the League of Nations has just published a handbook entitled *Guiding Principles for Studies on the Nutrition of Populations* by Professor E. J. Bigwood, of Brussels University.

The author has endeavoured to work out methods of enquiry which can be generally applied as to the actual food consumption and the state of nutrition of given population groups. The handbook is divided into two parts:

A. *Dietary surveys*

There are four types of dietary survey: investigations may extend over a whole country, or be limited to population groups, to families, or to individuals.

The author describes the technique of these surveys—weighing methods; method of records in household books, questionnaire method, etc.; he then deals with the analysis of the collected data from the standpoint of the physiology of nutrition and with the scales of family consumption coefficients which have to be used in comparing the results of enquiries concerned with groups of different age and sex composition.

The last two chapters of part I deal with diets from the economic standpoint and the statistical significance to be assigned to the results of surveys.

B. *Enquiries into the state of nutrition of populations*

In this part of his handbook the author discusses the somatometric (biometric, clinical and physiological) methods that may be suitably employed in these investigations. Special attention is given to the physiological methods, especially those for detecting latent hypovitaminoses and iron deficiency.

The handbook is completed by examples of surveys of various types in a number of different countries; it also comprises a terminological index and bibliographical references.

DIGITALIS PREPARATIONS SOLD IN INDIA

THAT a large proportion of digitalis preparations sold in India is below par in quality is a recent finding of the Biochemical Standardization Laboratory, Calcutta, which, since its inception nearly two years ago, has been making an all-India survey of the quality of medicinal preparations for which definite and recognized standards of comparison are available.

In the interests of patients and of scientific medical practice, it seems imperative that some form of control should be exercised by the State over drugs like digitalis.

All digitalis preparations issued for sale, it is suggested, should be tested and their potency controlled before they are released. Strict precaution should be enjoined regarding their storage in cool and dark places, preferably in cold storage where possible. All digitalis tinctures more than a year old should be re-tested for their potency, and if found below par, immediately withdrawn from clinical use.

The reasons why digitalis preparations sold in India have been found below standard quality are not clearly understood. A good deal of research has been carried out both in India and abroad regarding the stability of digitalis preparations, and it is now generally recognized that the glucosides of digitalis deteriorate at a fairly rapid rate when stored in a high temperature. Therefore, the hot and humid climate of India may bring about a rapid deterioration of all digitalis preparations, locally-made or imported from abroad.

The survey on which the Biochemical Standardization Laboratory bases its conclusions may be said to be fairly representative of the conditions existing in India. For the purpose of analyses, samples were obtained from practically all the provinces in British India. Altogether 110 samples were analysed biologically up to the end of 1938. These consisted of 102 digitalis tinctures, 4 dried leaves of digitalis and 4 digitalis powders.

Of this number, 87 were found to be below 80 per cent in strength compared to the international standard and 57 were below 50 per cent potency.

One hundred and two samples in this group were of Indian origin as was evident from the labels on the containers and only 8 of foreign make. It is not known whether the digitalis tinctures with Indian labels were prepared from leaf grown in India or from imported leaf.

QUININE CULTIVATION IN INDIA

'INDIA contains enough first-class land for an early resumption of cinchona growing', observes Mr. A.

Wilson, Deputy Director of Agriculture, Cinchona, Madras, in the Imperial Council of Agricultural Research, *Miscellaneous Bulletin* No. 29.

India produces only 70,000 lb. of quinine but consumes 210,000 lb. and therefore import 140,000 lb. mainly from Java. India's real need of quinine, however, has been estimated at 600,000 lb., hence the importance of extending cinchona cultivation in India.

The Royal Commission on Agriculture emphasized the importance of cheap quinine. On the advice of the Indian Research Fund Association, the Central Advisory Board of Health in July 1937 resolved that an officer experienced in cinchona cultivation should investigate areas most suited to its cultivation and the cost of production. The Imperial Council of Agricultural Research arranged and financed this investigation.

The two most important species utilized by cinchona plantations in India are known as *Cinchona ledgeriana* which predominates in Bengal, and *Cinchona succubra*, the red bark variety. The latter presents certain advantages for certain soils and elevations but the former, the principal variety in Bengal, has much greater commercial potentialities especially on account of its high content of the invaluable alkaloid.

There are one hundred million sufferers from malaria in India calling for an annual supply of some 600,000 lb. of quinine sulphate, or its equivalent in other forms. Immediately 38,000 acres of first-class cinchona land is available, and this is distributed in Bengal, Assam, Orissa, Bhutan, Sikkim, Madras, Travancore, Cochin, Mysore and Coorg. Much of the hill land which is not yet fully explored showed promise and will require further investigation in the future.

INDIAN-GROWN DRUGS

SAMPLES of valuable drugs from Kashmir hills have recently been acquired for exhibition in the Industrial Section of the Indian Museum (Botanical Survey of India). Most of these drugs are imported at present. If cultivated and manufactured in India all the requirements of the country could be met.

One of these is *Atropa belladonna* which grows in the Himalayan ranges at an altitude of 6,000 to 12,000 ft. In past years considerable quantities of the drug were exported from, and finished medicinal preparations imported into, India but in recent years, Indian pharmaceutical firms have begun manufacturing certain preparations of this potent drug. The export of the plant has consequently decreased.

Indian rhubarb or *rewand-chini* (*Rheum emodi*) is found growing wild in various parts of Nepal and Sikkim at altitudes of 4,000 to 12,000 ft. The Indian rhubarb is as good as the rhubarb imported from China.

Podophyllum emodi or *papra* (Hind.) is a small herbaceous plant in great demand by drug manufacturers. It is found growing wild from Sikkim Himalayas to the North-West Frontier.

As the local drug is indiscriminately collected and prepared, the American drug, *Podophyllum peltatum*, is still in demand by the Indian manufacturers. There is little uniformity of strength of the active principle in the drug collected in India. Its systematic cultivation may pay the investor, for the Indian product is much superior to the American species in strength of active principle.

SOURCE OF SANTONIN

Artemisia or *kirmala* (Hind.) is the source of the valuable drug santonin. The plant with a number of varieties is found growing in Kurram Valley and in Kashmir and one of them—*Artemisia maritima*—has been found to contain the valuable drug santonin. This plant is waiting for an enterprising manufacturer.

Another plant which is reported to be found growing wild in Kashmir Hills is *Hyoscyamus niger* or *khurasani ajowan*. Recently brought under cultivation, it gives the required percentage of alkaloid and has a good prospect of competing with the imported material, provided the prices are kept low.

Indian valerian or *Valeriana wallichii* grows wild in the mountain ranges extending from Kashmir to Bhutan

at altitudes ranging from 4,000 to 12,000 ft. If properly collected, it can replace the imported rhizomes of *Valeriana officinalis*.

Commonly known as foxglove, *Digitalis purpurea* was formerly imported into India, but in recent years the plant has been extensively cultivated in Darjeeling and Kashmir Hills and India has now little need to import this valuable drug from abroad.

OIL OF JUNIPER

The oil obtained from the berries of *Juniperus communis* and another species—*J. macropoda*—is of pharmaceutical importance. At present most of the oil is imported into India and it is worth while exploring commercial possibilities of this drug plant, found in plenty in the Western Himalayas.

A herbaceous plant and its seeds, *Plantago ovata* or *isabghul*, are in great demand. The plant grows in the lower hills as well as in the Punjab and Sind plains. A large quantity of the seeds is still imported into India, but by judicious cultivation India can meet her own needs.

The plant *surinjan* or *Colchicum luteum* is extensively found in the western temperate Himalayas, and the drug forms a good substitute for the official drug.

Aconitum chasmanthum grows abundantly in Kashmir. The root is regarded as an Indian substitute for the European drug obtained from *Aconitum napellus*.

THE TWELFTH MEETING OF THE ROSS INSTITUTE INDUSTRIAL ADVISORY COMMITTEE

IN addition to a great many interesting observations on important matters of health in many parts of the tropics the following brief abstract is of special interest to India:—

REORGANIZATION OF THE INDIA BRANCH OF THE ROSS INSTITUTE

Sir Malcolm Watson said:—I would like to express the thanks of the Standing Committee of the Ross Institute to Mr. E. A. Watson who has taken a very deep interest in this matter, and I am sure that it is very largely due to him that we have been able to get these very busy men in India to give some of their valuable time to the work of the Ross Institute.

I have been seeing in the last month or so many reports, sent to me by Dr. Ramsay, from medical officers and estate managers in many parts of India on the results which have come from the control of malaria, and it is quite evident that the number of people who are convinced of the economic value of malaria control is steadily increasing.

It is many years since I was in India, and I hope on my return from Rhodesia to visit India and have an opportunity of seeing for myself the work which has been done. But to read these accounts of the varied conditions that are being controlled in India makes me wish I could go next week instead of a few months hence. It is evident that a great and valuable work is being done there by the co-operation of the Ross Institute and the estate medical officers. It is very satisfactory to read that some places that used to be hotbeds of blackwater fever have not had a case for years. I remember that in 1908 the European population in the Dooars was almost threatened with extinction owing to malaria and blackwater fever.

We are trying to get a standard report for the use of tea estates and Dr. B. A. Lamprell, who is here to-day, has been deputed by the Assam Branch of the British Medical Association to co-operate with the London School of Hygiene and Tropical Medicine, in getting out a standard form of report for the tea estates. I am sure it will be a great help to the medical men to express in figures the results of their work. It will show whether they are getting results or not, and if they are spending their money wisely.

Dr. Lamprell spoke on the subject of medical statistics in the tea industry in Assam:—

The present position is unsatisfactory, and health returns often convey little. There is no uniformity in

the returns, and in some instances the figures representing malaria sick rates, total sick rates, etc., on estates, are not comparable even with the corresponding figures for the same estate in the previous year.

The matter was brought up at the meeting of the Assam Branch of the British Medical Association in 1932, and then it was agreed that some degree of uniformity in health returns for the industry was desirable. A committee was formed to make recommendations, but was unable to come to any agreement as to the best type of standard form. The matter was raised again in 1938, and at a General Meeting of the Branch it was unanimously agreed that uniformity in returning certain essential figures was most desirable.

Proper health returns are necessary in any public health organization, but in medical departments of industrial concerns they are obviously essential. The figures of sickness due to malaria, dysentery and other diseases of economic importance should indicate clearly the extent to which loss of work and life occurs from these causes. It is only when a clear idea is obtained of the cost of disease that there can be an assessment of the extent to which expenditure or prevention is economic.

I sincerely hope that with the help of the Department of Vital Statistics of the London School of Hygiene and Tropical Medicine it will be possible to draw up some monthly and annual forms for health returns which will be widely acceptable to the tea industry in Northern India.

A CAREER FOR EDUCATED WOMEN

'WHERE can we obtain trained health visitors' is a question which is being asked repeatedly by progressive Municipal Committees and District Boards. Educated Indian women are needed, in larger numbers than are at present coming forward for training, to meet this demand, which is the result of a growing appreciation of the importance to the nation of the health and well-being of the mother and child.

One of the reasons for the present lack of sufficient applicants for health visitors' training may be ignorance of the openings for women which this profession offers. It is certain that the work should make a strong appeal to educated Indian women, because it provides an occupation which is full of human interest and of great social value.

The health visitor after training is employed by local authorities or voluntary organizations for work in connection with maternity and child welfare schemes. She is usually attached to a welfare centre. Her duties include the holding of clinics in the welfare centre and the visiting of women and children in the homes. The training of *dais*, the supervision of midwives and health propaganda of various kinds are other aspects of her work. A health visitor does not attempt to cure disease but she endeavours by friendly advice to educate parents as to how they may bring up their children to be strong and healthy.

Schools for training health visitors have been instituted in Delhi, Bombay, Poona, Lahore, Calcutta, Madras and Nagpur, and the course of training varies from 9 months to 18 months.

Applicants for admission to the schools must be over 21 years of age and should possess a diploma in midwifery; a general nursing training is an added advantage. The cost of training varies in different centres, but a considerable number of scholarships is available.

Health visitors possessing diplomas of the health schools can obtain posts on salaries starting at Rs. 70–75 p.m. in Northern India and Rs. 55–60 p.m. in Southern India. A number of more highly paid posts are available for health visitors with experience and special ability, and women taking up this profession need have no fear of being unable to earn a good living.

COUNTESS OF DUFFERIN'S FUND

EXTRACT from the Minutes of the Executive Committee of the Countess of Dufferin's Fund, held on the 5th April, 1939.

* * * *

18. To consider what further steps can be taken to assist Indian medical women apart from those in the Training Reserve who intend to study in England.

18. The chairman proposed and all agreed that assistance could be given in the following ways:—

- (a) Advice should be offered by the Dufferin Office to Indian women intending to study medicine in England.
- (b) The services of our medical adviser in London should be available for advice, and also help in emergencies.

It was agreed that publicity to these arrangements should be given through notices to medical colleges in India, to the press, letters to the High Commissioner in London, the secretary of the Students Advisory Committee in the provinces, the women assistants to the Inspector-General of Civil Hospitals, of the U. P. and Punjab. The secretary was requested to draw up suitable letters and notices for the chairman's approval.

POST-GRADUATE STUDY IN GREAT BRITAIN

WOMEN medical students and doctors who are planning post-graduate studies abroad are invited to correspond with the Chief Medical Officer, Women's Medical Service, Countess of Dufferin's Fund Office, Viceregal Estate, Simla (Summer), Red Cross Building, New Delhi (Winter), from whom advice can be obtained before leaving India about the various diplomas and courses of study available, the qualifications needed for each, and in general about facilities for residence and study abroad.

In London the services of the Countess of Dufferin's Fund Medical Adviser are also available for similar advice and help in emergencies. Applications should be made in writing to Dr. A. C. Scott, c.s.e., c/o The High Commissioner for India, India House, Aldwych, London, W.C.2.

Students are strongly advised not to leave India without assurance that they are qualified for admission to the examinations they intend to take.

(Sd.) G. STAPLETON,
Secretary.

CAMERON PRIZE FOR PROF. DOMAGK

At a meeting of the Court of Edinburgh University the Senatus reported that the Cameron prize for 1939 had been awarded to Dr. Gerhard Domagk, Institute for Experimental Pathology and Bacteriology, I. G. Farbenindustrie, Elberfeld, Germany, in recognition of his discoveries—the well-known Prontosil—which initiated the treatment of diseases of bacterial origin by compounds belonging to be sulphonamide group.

The Cameron prize is awarded to a person who, in the opinion of the Senatus, has in the five years immediately preceding the award made any highly important and valuable addition to practical therapeutics.

THE DR. B. S. SHROFF MEMORIAL GOLD MEDAL OF THE BOMBAY MEDICAL UNION

THE following subject has been selected by the Bombay Medical Union for competitive thesis for the above prize for 1939:—

'Alcohol and Alcoholic Drinks—their use and abuse in India, with special reference to their effects on Health and Disease.'

The award will be in the form of a gold medal called the Dr. B. S. Shroff Memorial Gold Medal of the Bombay Medical Union.

The competitor must be (i) a duly qualified member of the medical profession holding a degree or degrees and diplomas from Indian and other universities created by statute, or (ii) a duly qualified member of the medical profession holding the diploma of Membership of College of Physicians and Surgeons of Bombay.

The thesis must be sent in six typed copies so as to reach the Honorary Secretaries, Bombay Medical Union, Bhavatsky Lodge Building, French Bridge, Chowpatty, Bombay, on or before the 31st October, 1939.

The thesis should be designated by a motto instead of the writer's name and should be accompanied by a sealed cover containing the name of the writer and his post-office address.

The name of the prize, the year of competition, the subject of the thesis, and the writer's motto should be superscribed on the cover.

No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and no contribution offered in one year will be accepted in any subsequent year unless it includes evidence of further work.

The accepted thesis shall be the property of the Bombay Medical Union.

All other thesis shall be returned if not accepted provided the returned postage expenses are paid in advance by the writer.

In the award of the prize to the successful candidate, the decision of the committee shall be final.

UNITED PROVINCES MEDICAL COUNCIL

Minutes of the meeting of the United Provinces Medical Council held in the committee room of the office of the Inspector-General of Civil Hospitals, United Provinces at Lucknow on 31st March, 1939.

RESOLVED that the D.T.M. & H. and D.C.H. qualifications, granted by the Royal College of Physicians of London and the Royal College of Surgeons of England, be registered as additional qualifications.

The council unanimously rejected the suggestion that sanitary inspectors and vaccination staff should be trained and authorized to inoculate against cholera and plague. The council came to this decision after mature consideration and on weighty grounds, as the risks involved would be too serious.

Some of the members of the council having testified that to their knowledge Dr. Mahudavalla had done nothing to warrant the removal of his name from the register, it was unanimously decided that Dr. Mahudavalla's name should be included in the register.

Resolved that the name of Dr. Surendra Singh, M.D. (Vienna), may be registered.

It was resolved that the name of Dr. Kishori Kumar Mathur, M.D. (Vienna), may be registered.

The case against Dr. Jagannath Prasad Sinha, M.B., B.S. (regn. no. 2853), of Benares, was considered.

It was resolved unanimously—

That the council do judge Dr. Jagannath Prasad Sinha to have been guilty of infamous conduct in a professional respect and do direct the Registrar to erase from the medical register the name of Dr. Jagannath Prasad Sinha.

Dr. Jagannath Prasad Sinha may however apply for his name to be registered in the medical register at the end of twelve months. He must then satisfy the council that he has not done anything against the code of medical ethics.

The council unanimously endorsed the following resolution passed at the United Provinces Medical Conference held at Agra in October 1938:—

Resolved (a) that this conference notes with concern the increasing evil of quackery in United Provinces where all sorts of suffixes and prefixes simulating recognized medical degrees or diplomas are being assumed freely by unqualified persons to advertise themselves as qualified medical men and requests the Government to take necessary measures to protect the public and the profession from the consequences of this evil, and

(b) that in the opinion of this conference it is now high time that the Government should make it a penal offence for anyone to use the prefix Doctor or Dr. before his name unless he possesses a degree of doctorate from any recognized university or possesses a medical qualification from one of the medical institutions recognized either by the Indian Medical Council or one of the Provincial Medical Councils or both.

STATEMENT FROM THE MEDICAL PEACE CAMPAIGN TO MEMBERS OF THE MEDICAL PROFESSION THROUGHOUT THE WORLD

REALIZING the suffering and disease which are caused by war, and accepting our medical responsibility to prevent disease as well as to treat it when developed, we urge the governments of the world to take action to make war impossible.

In particular we suggest that, in order to combat the present emergency, Great Britain, France and Russia should declare that they stand united and determined to resist all further aggression by military force if necessary; and that the governments of these countries should invite all other countries, irrespective of their form of government, to associate themselves with this declaration.

We maintain that the only way to eliminate all possibility of future war is the establishment of the rule of international law, based on the principles of justice to all and backed, so long as this remains necessary, by overwhelming military and economic strength. To this end we urge that a conference be called to discuss the practical measures which should be taken.

Finally, as an organization representative of medical opinion and regarding medicine as the most international and humane of all professions, we would remind our colleagues in all countries of the great part which they may yet play in influencing public opinion on behalf of peace.

Signed on behalf of the Medical Peace Campaign,

JOHN A. RYLE,
President.

INDIAN MEDICAL BIRTHDAY HONOURS, 1939

THE following are the names of medical men and others, associated with medical institutions, in the Indian Honours List of date 8th June, 1939. We offer them our congratulations:—

C.I.E.

Lieutenant-Colonel R. F. D. MacGregor, Residency Surgeon, Hyderabad (Deccan).

Lieutenant-Colonel F. J. Anderson, Professor of Surgery, Medical College, Calcutta.

O.B.E.

Major Bijeta Chaudhuri, Senior Medical Officer, Port Blair.

Mr. H. R. Rishworth, Principal Medical and Health Officer, G. I. P. Railway.

M.B.E.

Miss Una Frances Marie Morton, Principal, Women's Medical School, Agra.

Rai Bahadur R. N. Banerji, Medical Practitioner, Allahabad.

Mr. A. L. Greenway, Medical Officer and Quarantine Medical Officer, Kuwait, Persian Gulf Residency.

Mr. K. S. Mitra, Secretary, Medical College Hospitals, Calcutta.

Mr. Radha Krishna, Medical Superintendent, Silver Jubilee Tuberculosis Hospital, and Tuberculosis Clinic, Delhi.

Kaisar-i-Hind Medal (First Class)

Miss Mary Firth Guyton, lately of Farrer Zenana Mission Hospital, Bhiwani, Hissar District, Punjab.

Miss Grace Stapleton, Professor of Obstetrics and Gynaecology, Lady Hardinge Medical College, New Delhi.

Kaisar-i-Hind Medal (Second Class)

Mrs. Cecilia Burgess, Provincial Organizer, Sind Provincial Branch, Indian Red Cross Society, Sind.

Mrs. Constance Sylvia Heyland, Sister in charge, Radium Institute, Prince of Wales Medical College Hospital, Patna.

Miss Maria Johanna Caroline Sophie Rasmussen, Health Worker, Child Welfare Centre, Peshawar.

Miss Violet Riggs, Nursing Superintendent, Irwin Hospital, Delhi.

Kaisar-i-Hind Medal (Third Class)

Mrs. Amar Das, Medical charge of the Indian Army Maternity and Child Welfare Centre, Delhi Cantonments.

Miss Sigrid Johnson, Nurse, Clough Memorial Hospital, Ongole, Guntur, Madras.

Babu Sanat Kumar Chowdhury, Sub-Assistant Surgeon, Sadar Hospital, Bogra, Bengal.

Mr. Bimal Ranjan Dey, Sub-Assistant Surgeon, attached to the Staff of H. E. the Governor of Assam.

Sardar Bahadur

Sardar Salub Sardar Amrik Singh, Civil Surgeon (Retired), Gujranwala, Punjab.

Rai Bahadur

Mr. Kedar Nath Goyal, Civil Surgeon, Bulandshahr, U. P.

Rai Sahib Lekhraj Singh, Medical Officer in charge, Sadar Hospital, Kheri, U. P.

Mr. Ram Narain Sindhi, Civil Surgeon, Montgomery, Punjab.

Dr. Phanindra Nath Ghose, Vice-Chairman, Municipal Board, Dibrugarh, Assam.

Rao Bahadur

Mr. Calambur Ramamurti, Professor of Bacteriology (Retired), Medical College, Vizagapatam, Madras.

Mr. Ganpat Ramrao Goverdhan, Civil Surgeon (Retired), C. P. and Berar.

Vaidyaratna

Mr. Sukhramdas Tejbhandas Ojha, Ayurvedic Medical Practitioner, Sind.

Kaviraj Balukeswar Acharya Visagratna, Head Pandit, Adarsha Ayurveda Vidyalaya, Cuttack.

Khan Sahib

Saiyid Nisar Ahmed, Medical Officer in charge, Police Hospital, Moradabad, U. P.

Mr. Mohamed Yacoob Beg, Railway Assistant Surgeon, Burma Railways, Rangoon.

Rai Sahib

Mr. Bhawani Shanker Yajnik, Superintendent, Government Vaccine Depot, Patwadangar, Naini Tal District, U. P.

Lala Dharam Pal Gupta, Medical Officer in charge, Najibabad Dispensary, Bijnor District, U. P.

Babu Sushilananda Sen, Civil Surgeon (officiating), Purnea, Bihar.

Babu Sajani Kumar Chatterji, Officer in charge, Bacteriophage Laboratory, Patna.

Subedar Bashi Ram, Sub-Assistant Surgeon, Civil Hospital, Loralai, Baluchistan.

Mr. Jiwan Ram Maleri, Chief Medical Officer, Nabha State.

Mr. Santosh Kumar Barat, Assistant Surgeon, G. I. P. Railway, Jubbulpore, C. P.

Rao Sahib

Mr. Chella Suryanarayana Murti, District Veterinary Officer, Madras.

Mr. Dharmapuri Govindarajulu Nayudu, Medical Practitioner, Bezwada, Madras.

Mr. Baldeo Singh Chaudhuri, Superintendent, Civil Veterinary Department, Jullundur Division, Ferozepore, Punjab.

Current Topics

Mandelic Acid Therapy

By MEREDITH F. CAMPBELL, M.D.

(From the *New York State Journal of Medicine*, Vol. XXXVIII, 1st October, 1938, p. 1257)

DESPITE progressive improvement in medicinal anti-sepsis of the urinary system, the search is still on for a bacteriocidal agent which will be regularly satisfactory in the combat of the usual non-tuberculous urinary tract infections. During the past three years notable advances have been made in this field by the introduction of mandelic acid compounds and, most recently, para-aminobenzene sulfonamide, known commercially as sulphanilamide or prontosil. Each of these medications will produce clinical results in urinary infections which are strikingly superior to any heretofore obtainable by oral chemotherapy. The employment of the sulphanilamide compounds is perhaps the more fascinating because the *modus operandi* is unknown but my brief presentation here will be concerned only with the assigned subject—mandelic acid therapy.

Mandelic acid therapy is the illustrious direct descendant of the ketogenic dietary treatment of urinary infection. The discovery and application of the therapeutic mechanism common to each is historically interesting. In 1931 Helmholtz noted that the urine of an epileptic child in therapeutic ketosis (ketogenic diet) failed to show bacterial clouding after standing for a week in a warm room. Investigation disclosed the bacteriocidal property of ketone urine when the hydrogen ion concentration (pH) is less than 5.5. Fuller discovered the important acidifying factor in ketone urine is *lævo*-rotatory betaoxybutyric acid and when the concentration of the last is 0.5 per cent or greater and the pH level is below 5.5, the urine is not only bacteriostatic but commonly bacteriocidal.

During an investigation to obtain an organic acid which would be excreted in the urine and the action of which would be like that of β -hydroxybutyric acid, Rosenheim hit upon mandelic acid. He was the first to employ mandelic acid clinically—and with notable success. Mandelic acid is a pure white crystalline hydroxyacid represented by the chemical formula $C_6H_5CH(OH).COOH$. Following ingestion it is excreted unaltered in the urine. Like β -hydroxybutyric acid, mandelic acid is bacteriocidal in the urine only in a concentration of 0.5 per cent or greater and when the urinary acidity is pH. 5.5 or greater. In most instances of failure to sterilize the urine by mandelic acid therapy, it will be found that the conditions just mentioned have not been fulfilled. The concentration may be inadequate because of (1) inadequate dosage or (2) renal failure to excrete. Mandelic acid in large doses is a renal irritant, which may account in some instances for a lowered output of the acid or the kidneys may already be impaired when the medication is given. An inadequate urinary acidity is a frequent cause of failure but as a rule is readily rectified by the auxiliary administration of a strong acidulant such as ammonium chloride, calcium chloride or ammonium nitrate. Failure to keep the urine sufficiently acid through neglect of a constant check on the urinary pH. is doubtless a commoner cause of failure than inadequate mandelic acid excretion. Attention will again be directed to these factors for without their close observance, failure is almost certain to replace possible success with the method.

Indications for mandelic acid therapy.—Mandelic acid is indicated in the treatment of the usual non-tuberculous infections of the urinary tract. It has been ineffectual against tuberculous invasions; I have found no record of its use in the rare infestations such as bilharziasis, actinomycosis, etc.

During the therapeutic period the urine must be carefully and periodically checked for evidence of renal irritation (albumin, occasionally blood, casts) and if

this is disconcerting, the medication must be discontinued. Yet it must not be stopped because of a faint trace of albumin or a relatively few scattered casts.

The pH. should be determined twice daily so that sufficient acidulant may be given to keep the reaction below pH. 5.5. Adults can be taught to control the last factor themselves and will report any unusual developments while taking the medication. The two indicators most commonly used now to determine an acidity greater than pH. 5.5 are methyl red and nitrazine. Methyl red is red on the acid side of pH. 5.5 and yellow on the alkaline side. This is used either as a methyl red test paper or as a solution, a few drops of which are added to the urine to be tested. I regularly employ nitrazine paper or nitrazine solution (Squibb) as this enables one to make a rapid approximation of the urinary pH. Nitrazine (sodium dinitrophenylazo-naphthol disulphonate) is sensitive to N/10,000 acid or alkali; its colour is yellow at pH. 5.0, mustard at pH. 5, olive at pH. 6, grey-blue at pH. 7, and blue at pH. 8. A colour chart with pH. 0.5 gradations enables one to estimate the urine titre with rapidity and an accuracy adequate for clinical application. A potentiometer gives the most correct estimation of the pH. but its use is more desirable than essential.

Children develop acidosis readily and it is therefore usually wise to start them with a slightly less than average dose, and when mandelic acid therapy is employed in infants, the physician must be keenly alert to any unfavourable reaction—especially acidosis. Yet this does not contra-indicate its use in the very young; I regularly employ it in children of all ages—the youngest to date was ten weeks old.

Contra-indications.—Because mandelic acid is excreted unaltered in the urine and is a potent renal irritant, its employment is contra-indicated when the renal function is impaired as evidenced by a phenol-sulphonphthalein test, specific gravity fixation, etc. This irritant action is of special importance in patients whose impaired kidneys are still further injured by the acid and whose function may be alarmingly reduced. In such cases, not only is the urinary excretion lessened, but the mandelic acid continually ingested is retained in the body to produce acidosis. This course is often more rapid and severe when a strong acidulant such as ammonium chloride or calcium chloride is co-administered. A tender age is no contra-indication (*cf. supra*) to the employment of mandelic acid therapy and it may be freely administered to elderly patients whose kidneys are relatively unimpaired.

Medication and dose.—Mandelic acid was first administered as a sodium salt (sodium mandelate) compounded of mandelic acid and sodium bicarbonate. Ammonium mandelate induces a greater urinary acidity and is the compound now most generally employed although other mandelate salts such as ethanalamine mandelate have more recently been introduced. Ammonium mandelate is extremely salty and disagreeable to take, hence it is usually given as an elixir or a syrup yet I have fewer complaints when it is taken as a tablet (0.5 gm. each for adults; 0.25 gm. each for children). Ingestion of the medication is sometimes made more acceptable by the addition of liquorice or chocolate flavouring.

The dose of ammonium mandelate that I employ in children ranges from 2 gm. per day in young infants to 10 gm. a day at twelve years and given in divided doses three or four times a day, preferably after meals and just before retirement. Infants less than six months of age are given 2 gm. in twenty-four hours, children six to twenty-four months old may be given 2 to 4 gm., patients two to four years are given 4 to 6 gm., and from five to twelve years, 6 to 10 gm. are given. Ammonium chloride is given in addition in sufficient amount to render the urine more acid than pH. 5.5. Usually 2 or 3 gm. (30 to 45 gr.) daily is sufficient in children but I have employed doses ranging from 0.7 gm. (10 gr.) to 6.7 gm. (100 gr.) per day. In any event, sufficient acidulant must be given to attain a urinary acidity of less than pH 5.5.

In adults the dose of ammonium mandelate is correspondingly greater than in children, 9 to 14 gm. (135 to 210 gr.) with an average of 12 gm. being given together with the necessary amount of acidulant to make the urinary acidity pH 5.5 or less. As a rule, this means beginning with 3 to 5 gm. (45 to 75 gr.) per day and varying the intake to meet the pH requisite.

Were the precaution more regularly observed, it would be unnecessary to direct attention to the fact that all alkalinizing agents such as sodium bicarbonate, magnesium hydroxide, citrus fruits, etc., must be avoided while one is attempting to achieve the urinary acidity requisite to successful mandelic acid therapy.

During the therapeutic period the fluid intake is reduced to 1,200 to 1,400 c.c. per day in an adult. One must be extremely careful about reducing the fluid intake of any child and I, therefore, say nothing to the mother about altering this factor nor is the daily intake comparably reduced in my young hospitalized patients.

A daily or, better, a twice daily check of the urine titre is essential during the period of treatment with mandelic acid. These repeated studies guide one in the medicinal maintenance of the requisite acidity. They disclose evidence of renal irritation consequent to the medication and, extremely important, reveal clinical progress as indicated by diminution of bacteria and inflammatory products in the urine.

This therapy is usually effective in forty-eight to seventy-two hours, at least striking improvements will be noted in that time, and the treatment should be continued. If the urine cannot be sterilized (as evidenced by two negative cultures of catheterized specimens) in two weeks, the treatment should be discontinued for a week or ten days and then intensively resumed or a change to prontosil, for example, may be made. If a second effort fails and the therapeutic requisites have been met, it is unlikely that further effort will be successful—at least until previously unrecognized associated etiologic factors such as obstruction, primary focal infection elsewhere, etc., are eliminated. If none of these factors can be proved to exist, change antiseptics.

A word is in order concerning the collection of specimens in the study and treatment of urinary infections. Bacteriologic study implies the aseptic collection of specimens. For this reason all females must be catheterized, even the youngest infants. With proper technique and by using only a soft rubber catheter which requires introduction under visualization, catheterization can be performed without injury in a female of any age. Once the catheter is introduced, a few c.c. of urine should be permitted to flow out before specimen collection is begun, to carry away any debris which may have entered the catheter eye.

Clinical evaluation based on microscopic and bacteriologic examinations of voided specimens are misleading in females, no matter how vigorously the vestibule, introitus, labia, urethral orifice, etc., have been cleaned. Pus cells, epithelial debris and bacteria washed into the specimen during urination interfere with an accurate conception of these elements in the bladder urine. Repeatedly the writer has been asked to perform complete urologic examination in girls said to have 'chronic pyelitis', the diagnosis being based on studies of voided specimens laden with pus cells, but in whom vesical catheterization has shown normal sterile urine.

In the male the specimen can be satisfactorily obtained when the prepuce is well retracted behind the glans, the glans and meatus are thoroughly cleansed with an antiseptic solution such as oxycyanide or bichloride of mercury 1:500, and the patient passes a few c.c. before the voided specimen is collected in a sterile receptacle. If this cannot be properly carried out, the male also should be catheterized. The culture tube should be implanted with at least 0.5 and preferably 1 c.c. of the urine.

TEST OF CURE

The patient should not be discharged cured until two negative cultures of properly collected specimens have been obtained. Although most sterile urine is pus-free at the termination of a non-tuberculous urinary infection, there may be scattered leukocytes in urine repeatedly sterile to culture. In other words, the bacteriologic culture rather than the absence of leukocytes is the all important criterion of successful treatment. If this test of cure is observed the incidence of 'recurrence' of urinary infection will be extremely low. Most clinical episodes commonly designated as recurrences of 'pyelitis' are merely exacerbations of a smouldering asymptomatic and previously unrecognized or inadequately treated urinary infection. The exacerbation may have been induced by urinary obstruction, severe constipation, the acquisition of a focal infection elsewhere, or any of the usual predisposing etiologic factors in urinary infections. A plea is therefore made for correct (aseptic) collection of urine specimens when urinary infection is under study and treatment and also for at least two negative urine cultures as the test of cure.

REACTIONS

Cook reported nausea and vomiting in less than 1 per cent of patients receiving mandelic acid therapy at the Mayo Clinic and only 10 per cent developed a mild diarrhoea. My observations suggest that in general usage the incidence of such reactions is probably much higher. Yet there is no urinary antiseptic which may not provoke distressing enteric or vesical reactions—witness hexamine (urotropine), caprokol, acriflavine, pyridium, prontosil, *ad infinitum*. The irritant effect of mandelic acid on the kidney has been discussed. Hematuria may develop but is unusual.

The results are most gratifying in the usual bacillary infections. Experimentally, Helmholz found that *in vitro* mandelic acid is most effective against *Escherichia coli* and *Proteus ammoniae*, and less effective against *Salmonella*, *Aerobacter*, and *Pseudomonas*. The last two organisms are most resistant of the common bacilli. It is known to be least effective against the Gram-positive cocci, notably *Streptococci* and *Staphylococci*. Still with rigid clinical control these infections may sometimes be eradicated. Moreover, *Streptococcus fecalis* has been found almost as vulnerable to the treatment as *B. coli*.

Published results of mandelic acid therapy suggest that with mutual diligence of the patient and physician, at least three-fourths of patients with uncomplicated urinary infection can be cured. Rosenheim cured 71 per cent of eighty-eight patients. Of thirty-seven failures, twenty-one had urinary stasis or obstruction; two could not be satisfactorily acidified. Carroll Lewis and Kapel reported fifty cases of urinary infection treated by mandelic acid. Of thirty-seven *B. coli* infections, twenty-seven were sterilized. But one of six cases of *B. proteus* was cured; none of the *Staphylococcus* infections were cured. Yet in a series of seventy-five patients reported by Cook and Buchtel managed with special care, the urine was sterilized in sixty-one cases or 81 per cent. In forty-one adults thus treated by the writer, twenty-two (54 per cent) were cured as evidenced by two negative cultures of aseptically collected specimens. The uncured patients nearly all suffered from prostatitis, or had poor renal function. In thirty-four children, I achieved success in twenty-six or 76.4 per cent.

Mandelic acid escapes being the perfect urinary antiseptic by (1) being active only in a highly acid urine, (2) producing reactions in the alimentary tract and (3) having its efficiency severely influenced by the renal function. Moreover, it may provoke renal irritation.

The causes of failure in mandelic acid therapy may be briefly summarized as follows:—

- (a) Failure of patient to co-operate.
- (b) Inadequate dosage; in mandelic acid therapy homeopathic doses are doomed to failure.
- (c) Inadequate acidification; this is readily corrected.
- (d) Poor renal function: this may be due to

hydronephrosis, Bright's disease, chronic pyelonephritis, polycystic kidney, etc. Poor renal function may greatly reduce the quantitative output and excreted concentration of mandelic acid. The excretion of the necessary acidulant (e.g., ammonium chloride) is correspondingly diminished.

(e) Unusual virulence of the invading organisms.

(f) Residual urine, whether due to obstruction, neuromuscular inertia, or atony consequent to long-standing infection, may render bacteriologic cure difficult or require eradication of the residuum before the antiseptic can become effective. Stone, tumour or foreign bodies in the urinary tract may likewise prevent urinary sterilization. Chronic prostatitis, by continually pouring infection into the posterior urethra, may keep the urine from being sterilized or may reinfect when cure apparently has been achieved.

(g) Inadequate period of treatment: the medication should be given a trial of not less than one week and preferably ten days, unless individual idiosyncrasy prohibits.

SUMMARY

Although the ideal urinary antiseptic is yet to be obtained, mandelic acid therapy marks a notable advance in this important chemical field. This treatment can be employed in most patients with the usual non-tuberculous bacillary urinary infections, yet it has definite limitations as discussed under contra-indications and also causes of failure. By close observance of the indications, contra-indications, and technique as herein outlined, mandelic acid therapy may be expected to be successful in three out of four cases.

Reviews

THE MEDICAL ANNUAL: A YEAR BOOK OF TREATMENT AND PRACTITIONER'S INDEX.—

Edited by H. L. Tidy, M.A., M.D., F.R.C.P., and A. R. Short, M.D., B.S., B.Sc., F.R.C.S. Fifty-seventh Year. 1939. John Wright and Sons, Limited, Bristol. Pp. lvi plus 660. Illustrated. Price, 20s.

The greatest problem that the publishers of this excellent book must face each year is keeping the size of the volume within reasonable bounds. It has now reached the maximum size that ordinary binding and the wrists of readers will stand, and for some years the publishers have wisely refused to go beyond this limit; in fact this year they have been able to spare a few pages. Nevertheless, the individual articles do not show any signs of undue compression.

Sulphanilamide has a course permeated into every corner of medical practice during the year, so much so that it is refreshing to be able to read any article in which its success or failure is not the main theme. A good summary of the important advances in this form of therapy is given under 'chemotherapy of bacterial diseases'.

With the advance of so-called civilization new cures come along, but also new diseases. We do not refer only to the toxic effects of the cures themselves, when these are powerful drugs, but to such things as traffic lights and pneumatic drills and rivetters. It is a matter of surprise that pneumatic drills, which must precipitate psychoses amongst many people whose office or house is in the neighbourhood of the road menders', or spoilers', operations, cause very little morbid changes in those who operate them—unless of course they happen to strike a high-powered electric cable. There is in this volume a good summary of an interesting and important paper in the *Journal of the American Medical Association* on the neurological effects of traffic lights on the motor-car driver. Whilst designed to obviate collisions between cars, traffic lights cause repeated 'collision', in the Pavlov sense, within the central nervous system of the driver. Pavlov showed that the quick succession of excitatory and inhibitory reflexes produced a state of nervousness in the dog; this American writer considers the stimuli producing such reflexes have their counterparts in the green and the red lights. The interposition of the yellow light—which is not usual in the United States—must help to alleviate this collision of reflexes, but the 'Schubert' type of traffic light, in which there is an indicator that warns you how much longer each light will last will obviously reduce this collision considerably and seems to have few disadvantages, though it would not be applicable to the hand-operated lights.

The nomenclature of disease is large enough and one naturally hesitates to add to it, but certain facts have to be faced. Technical words, despite the popular idea that they are invented to confuse the layman, are

introduced to facilitate communication between experts, as by the use of a single word it is usually possible to convey an idea that would otherwise necessitate many words. Diseases undergo changes, and further our knowledge of diseased states increases, so that a disease syndrome which at the time appeared to be specific is later found to include more than one pathological state. The word *pneumonitis* which has recently been introduced describes a condition which is distinct pathologically, radiologically, and clinically from pneumonia; it is better to introduce a new word than to continue to refer to it as a mild or atypical pneumonia, or an unresolved pneumonic patch. This matter is discussed at some length.

Another subject that is selected for special discussion is the sedimentation rate. This simple procedure has been carried out, during the last twenty years, in a very large number of individuals suffering from various diseases, and extravagant claims have been made for it as a diagnostic and prognostic method. The time has come to take stock of all this work and this has been done concisely but thoroughly by Dr. P. N. Panton. Its diagnostic value can be ignored as it is increased in so many diverse pathological states but as a prognostic procedure in certain diseases 'in which it is otherwise difficult to find a mathematical measure of change', it is useful; tuberculosis and leprosy are examples of such diseases.

Tropical diseases have been dealt with by Dr. P. Manson-Bahr and are on the whole done well, but one is a little surprised to find under the heading 'malaria' that the Ascoli method of treatment and the inevitable prontosil are the only two subjects chosen for mention; for the latter only one paper is referred to.

The term 'lymphogranuloma inguinale' is retained, but the general tendency at present is to drop this term, as the condition is anything but a granuloma; 'lymphopathia venereum' is a much more satisfactory term.

Nutrition and diet have been given the special attention they deserve.

Drs. Stanley Davidson and H. W. Fullerton have written most of the sections on blood diseases and anæmia, including tropical macrocytic anæmia and have given even balanced accounts of recent work.

There are an unusually large number of plates, skiagrams, black and white illustrations of technique of superficial lesions, and of pathological specimens, and coloured plates of skin diseases.

The great value of the *Medical Annual* is that it forms a permanent addition to one's library and, if one looks up what has been said on any particular subject during the past few years, one gains a very complete and up-to-date conception of that subject.

The year's volume is well up to the usual standard.

FRACTURES AND DISLOCATIONS IN GENERAL PRACTICE.—By John Hosford, M.S. (Lond.), F.R.C.S. (Eng.). 1939. H. K. Lewis and Company, Limited, London. Pp. viii plus 274, with 71 illustrations. Price, 12s. 6d.

This book, which is a recent addition to the 'General Practice' series published by H. K. Lewis and Co., should prove popular as it provides, within a small compass, a reliable account of all the common fractures and dislocations.

The first part of the book discusses general principles, and separate chapters are devoted to important subjects such as the use of plaster, continuous traction, complications of fractures, and so on. To emphasize the importance of combining rigid immobilization of a fracture with active use of the rest of the limb, Mr. Hosford quotes the case of a patient who, 'With a fracture of the tibia and fibula immobilized in plaster from the toes to the tubercle of the tibia drove a car 200 miles as well as spending an active holiday on the Broads, twice falling into the water. Such activities', he continues, 'Are encouraged....'

When skeletal traction is required the author prefers to use a Steinmann's pin rather than a Kirschner wire. It would certainly seem that the Steinmann's pin has been returning to favour during the last four years, possibly due to the influence of Böhler.

The second part of the book deals with the common fractures and dislocations systematically. If any part deserves special mention it is the modest section on fractures of the os calcis, a condensation of a previous publication of the author. The final diagnosis of these fractures depends upon the x-ray findings, and a special oblique view in addition to a lateral view is advised. Böhler's method of reduction is described.

An appendix containing short biographies of Pott, Colles, Smith, Thomas, and Bennett forms an interesting conclusion to this admirable little book.

W. McN. N.

A MANUAL OF FRACTURES AND DISLOCATIONS.—By B. B. Stimson, A.B., M.D., Med. Sc.D., F.A.C.S. 1939. Henry Kimpton, London. Pp. 214. Illustrated with 95 engravings. Price, 12s. 6d.

This manual is intended primarily for medical students, and the authoress has therefore limited herself to a brief outline of the diagnosis and treatment of fractures and dislocations.

In the first part entitled 'General Considerations' the student will find much that is useful and interesting. For a thorough classification of fractures or a description of delayed union, to mention only two subjects, he will have to refer elsewhere.

The remaining three parts of the book describe in turn fractures and dislocations of the upper extremity, the trunk, and the lower extremity. A few x-ray photographs to supplement the numerous line drawings would be an improvement; they might well displace the tables of percentages of occurrences (sometimes carried to three places of decimals) to which the average student will pay no attention.

After the reduction of a Colles' fracture it is stated that the wrist should be placed in palmar flexion and ulnar deviation to maintain the reduction. We cannot agree with this at all.

Lorenz Böhler is responsible for very many advances in the principles and technique of treatment of fractures, but no mention of his work is to be found in this book.

W. McN. N.

INFECTIONS OF THE HAND: A GUIDE TO THE SURGICAL TREATMENT OF ACUTE AND CHRONIC SUPPURATIVE PROCESSES IN THE FINGERS, HAND AND FOREARM.—By A. B. Kanavel, M.D., Sc.D. Seventh Edition. 1939. Baillière, Tindall and Cox, London. Pp. 503. Illustrated with 229 engravings, many in colour. Price, 30s.

Our knowledge of the ætiology and principles of treatment of infections of the hand owes much to

Kanavel whose work, begun over twenty-five years ago, is embodied in this well-known monograph, now in its seventh edition.

The applied anatomy of the hand has, as in previous editions, been given special prominence, and here is to be found the original description of those major fascial spaces which are now often called Kanavel's spaces.

The recognition and treatment of tenosynovitis is discussed at greater length, and a section has been added describing the use of splints for the after-treatment of infections of the hand.

The sulfanilamide drugs receive only brief mention on the grounds that they have not yet had a thorough try-out.

Throughout the book the clarity of the text and beauty of the illustrations are remarkable; and it is hoped that although Kanavel died last year, the work of revision for future editions will be taken up by his collaborators.

W. McN. N.

THE COMMON DISEASES OF THE SKIN: A HANDBOOK FOR STUDENTS AND MEDICAL PRACTITIONERS.—By R. Cranston Low, M.D., F.R.C.P.E., F.R.S.E. Third Edition. 1939. Oliver and Boyd, Edinburgh. Pp. xiv plus 319, with 148 illustrations (8 of which are in colour). Price, 10s. 6d.

This is one of a number of very short books on skin diseases that are available in the English language. It is stated in the preface to be based on the lectures of the author and reading it gives the impression that it must be very largely in the actual words of these lectures.

One of the reasons for the brevity of this book is the fact that syphilis has been omitted as this is well dealt with in books on general medicine, and in any case now that the Wassermann reaction can be done almost anywhere the diagnosis of syphilitic skin lesions practically never rests on clinical appearances alone, so we are inclined to agree with this omission.

Practically no references are given to other workers so the book is the expression of the personal opinions of one dermatologist, with all of which others will not be in entire agreement.

The need for expansion is evidenced because the first edition which appeared in 1927 occupied 219 pages whereas the present one is 315 pages, and there are many more illustrations.

It is a useful handbook for the general practitioner, but as indicated above it is limited to the views of a single dermatologist, and despite the fact he is a very experienced one, it rather lessens the appeal of the book.

P. A. M.

RECENT ADVANCES IN FORENSIC MEDICINE.—By S. Smith, M.D., F.R.C.P., D.P.H., and John Glaister, M.D., D.Sc., J.P. Second Edition. 1939. J. and A. Churchill, Limited, London. Pp. viii plus 264, with 85 illustrations. Price, 15s.

FORENSIC medicine offers a vast field for the writer and it must have been difficult to decide on the scope of this book, but the choice of subjects seems to be a very satisfactory one. It would be difficult to find a better description of the theories or of the technique of blood grouping, and the discussion on the medico-legal application in cases of questioned paternity is a well-balanced summary of the accepted scientific point of view; in this matter the law is being a little obtuse at present, though there are signs of improvement, and the new bill that is being introduced should clarify many points of law. The general opinion is that non-conformity of types based on Bernstein's theory is absolute proof of non-paternity, and that that based on von Dungern and Herszfeld's, beyond the point where this coincides with Bernstein's, is very strong evidence of non-paternity. There are apparently one or two 'authentic' exceptions to the inheritance of blood groups according to the latter theory, but who is to say what is an authentic exception? This depends on whether you take the 'Cæsar's wife' point of view or

are the sort of person who insists on the bishop's Wassermann test being done.

The chapter on the medico-legal examination of hair is a fascinating one and opens up great possibilities, though it will not fall to every doctor's lot to have to identify the hair of an aye aye (whatever it is), of an Arabian baboon, or of a Diana monkey, nor to say whether a particular specimen is a female pubic hair, or from a moustache, but, should he be called upon to do so, the reviewer knows no other collected source of such information.

The chapter on testing alcohol in the blood is also an important one. Purves Stewart's table for the correlation of the alcohol in the blood and the clinical examination is given. 'Not drunk is he who from the floor can rise and drink and ask for more' (200 mgm. or less of alcohol per 100 c.cm. of blood). 'but drunk is he who prostrate lies without the power to drink or rise' (350 mgm. per 100 c.cm.). This is not, however, the view that the magistrate of to-day takes.

The book is a very valuable contribution to the subject, a worthy member of this excellent series of recent advances.

SPINAL ANÆSTHESIA.—By Louis H. Maxson, A.B., M.D. 1938. J. B. Lippincott Company, Philadelphia and London. Pp. xxii plus 409, with 69 illustrations. Price, 30s. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 20

MR. MAXSON'S *Spinal Anæsthesia* is a welcome addition to the very few books that are entirely devoted to this subject.

Since the impetus given to spinal anæsthesia during recent times by George Pitkin of New Jersey a vast amount of work on the subject has been done and the literature of the last decade is so extensive that the author has done a real service by embodying in his work everything that is essential.

The subject-matter throughout the book has been dealt with in detail with due regard to brevity consistent with clarity and in a style quite impressive. Mindful of the fact that a clear conception of the anatomical, physiological and physical factors in spinal anæsthesia is so essential for the production of uniformly satisfactory and safe anæsthesia these aspects have been thoroughly discussed. The chapters dealing with difficulties, dangers, mortality, advantages, disadvantages, indications and contra-indications have been presented in a manner free from bias—a tendency from which few writers on spinal anæsthesia are immune. Opinions of well-known authorities on the subject have been freely quoted and controversial matters have been discussed from every point of view. The few diagrams and charts are well chosen and instructive.

On the whole it is a comprehensive and up-to-date work on spinal anæsthesia which will prove immensely useful to the student, the anæsthetist and the surgeon alike.

M. C. G.

RADIATION THERAPY: ITS USE IN THE TREATMENT OF BENIGN AND MALIGNANT CONDITIONS.—By Ira I. Kaplan, B.Sc., M.D. 1937. Oxford University Press, London and New York. Pp. xxviii plus 558. Illustrated. Price, 30s. Obtainable from Oxford University Press, Bombay and Calcutta

DR. IRA KAPLAN'S new book on radiation therapy is a comprehensive and practical book on the therapeutic uses of x-rays and radium. The author is well qualified for the important task he has undertaken for, in addition to being director of some of the most important radiotherapeutic clinics in New York, he is also editor of the therapeutic section of the *Year Book of Radiology*.

The book deals with radiation therapy as employed in the treatment of benign as well as malignant diseases. It is based on the author's experience in treating patients in both special cancer and general hospitals, as well as in private practice. It aims at giving the student, the general practitioner, as well as

the specialist, an understanding of the fundamentals of irradiation, and enumerates the conditions for which this form of therapy is of value.

It is perhaps surprising to some of us to see the long list of benign conditions which are amenable to radiation treatment. Diseases as widely separated as erysipelas, carbuncle and asthma respond favourably.

The book covers a wide range of subjects including the whole field of radiation therapy by radium and x-rays. If one were to offer criticism it is that the descriptions of the technique employed is in many instances too vague to be of real value to the worker. The dose of radium too is expressed in milligramme hours—a method which is open to objection.

As pointed out by another reviewer, there are a number of typographical errors which can be avoided.

We hope these defects will be remedied in a new edition.

J. A. S.

CLINICAL ELECTRO-SURGERY.—By G. M. Blech, G.C.S., G.C.G., M.D., LL.D. With Chapters by H. A. Colwell, M.B., Ph.D., M.R.C.P., and B. W. Windoyor, M.B., B.S., F.R.C.S., D.M.R.E. 1938. Oxford University Press, London and New York. Pp. xxvii plus 389. Illustrated. Price, 21s. Obtainable from Oxford University Press, Bombay and Calcutta

DR. BLECH, with the object of acquainting practitioners with the scope and limitations of electro-surgery, has produced a most useful and interesting book.

While reminding us that this branch of surgery has to some extent lost ground through the errors of over-enthusiastic or ignorant users, he puts forward its just claims in such a reasonable manner as to inspire confidence in his recommendations.

The physics of high frequency currents is not described, but an adequate glossary of technical terms is provided, and a chapter on the historical development of electro-surgery serves as an introduction to a section devoted to general principles of technique, equipment, and so on.

The second section describes electro-surgical operations on the various parts of the body. Special emphasis is laid on the rule that electrotomy is the only permissible method of incision in relation to a recognized or suspected malignant tumour.

It is not clear why a chapter on the radiotherapy of neoplasms has been contributed by the author's British colleagues, Drs. Colwell and Windoyor. But it is well written and maintains the high standard set by the rest of the book.

THE MEDICAL APPLICATIONS OF THE SHORT WAVE CURRENT.—By W. Bierman, M.D. Including a Discussion of its Physical and Technical Aspects. By M. M. Schwarzschild, M.A. 1938. Baillière, Tindall and Cox, London. Pp. xvii plus 379. Illustrated. Price, 22s. 6d.

DR. BIERMAN'S book presents a practical consideration of the therapeutical effects of the application of the short wave current. This includes consideration of the physical character of the current. Its influence on the living human body in the normal and diseased state. An understanding of the pathologic processes which we hope to effect by its aid.

As a scientific work it has the advantage of being both practical and well balanced. The early chapters are devoted to the history, physics, and physiology of the subject. This part of the work has been mainly written by Dr. Schwarzschild, a well-known authority on this subject. The following chapters on technique and clinical application are well worthy of study by anyone interested in the subject. The technique is carefully described with many illustrations which should be a considerable help to the practitioner. Clinical applications are discussed at length and the results of other workers are also discussed.

There is an excellent index so that it is possible for the busy practitioner to look up the disease in which he is interested, the applicability of this form of

therapy, and the technique of application, readily and without wading through irrelevant matter.

There are of course faults inseparable from the treatment of this kind of subject. In some places the discussions tend towards verbosity and the reader is left involved in a plethora of information from which it is difficult to draw any positive conclusion. On the whole, however, the impression given by this book is that it provides a sound working guide to the employment of short wave therapy in general practice. The book combines the merits of an intelligible presentation of the scientific and medical aspects of this treatment with an annotated catalogue of world-wide experiences in the treatment of a large number of diseases.

J. A. S.

PRINCIPLES OF MEDICAL STATISTICS.—By A. Bradford Hill, D.Sc., Ph.D. Second Edition. 1939. Published by The Lancet Limited (7, Adam Street, Adelphi), London. Pp. vii plus 189. Illustrated. Price, 6s.

It is about 18 months since we drew attention to the first edition of this valuable book in an editorial note on medical statistics. We particularly commended it to would-be contributors to this journal, and there has been some evidence during the last year that our advice was not unheeded.

The book has obviously been a great success; there is little change in this new edition, as little improvement was possible. The author says that he has endeavoured to clarify certain points which appeared to confuse readers of the first edition, and he has added a chapter in which the usual methods of calculating standardized death rates are illustrated and discussed in detail.

We can only repeat what we said about the first edition; it is a book for which there was an obvious demand and it supplies that demand in the best possible manner.

FUNDAMENTALS OF PHYSICAL EXAMINATION.—

By G. G. Deaver, M.D., B.P.E. 1939. W. B. Saunders Company, Philadelphia and London. Pp. 299. With 126 illustrations. Price, 12s. 6d.

THE purpose of the book is to provide physical educators, students, public health and school nurses with a manual that will aid them in recognizing the early manifestations of abnormal functioning of the body and in understanding the technique and medical nomenclature of the physician.

The different chapters deal with how the medical history has to be taken, and the physical examination of the different systems and the different tests of efficiency of vision, hearing, muscular power, etc., have to be carried out. Besides containing the actual methods of conducting an examination, each chapter contains 'Lessons to be written', 'Laboratory work' and a 'Self test', three outstanding aids that have long proved valuable media for effective teaching.

The book is well written and gives the information necessary for the recognition of early symptoms and signs of bodily disease and the detection of bodily deformity. It should prove useful to those for whom it is written.

P. C. S. G.

A DICTIONARY OF SCIENTIFIC TERMS: PRONUNCIATION, DERIVATION, AND DEFINITION OF TERMS IN BIOLOGY, BOTANY, ZOOLOGY, ANATOMY, CYTOLOGY, EMBRYOLOGY, PHYSIOLOGY.—By I. F. Henderson, M.A., and W. D. Henderson, M.A., B.Sc., Ph.D., F.R.S.E. Third Edition. Revised by J. H. Kenneth, M.A., Ph.D., F.R.S.E. 1939. Oliver and Boyd, Limited, Tweeddale Court, Edinburgh. Pp. xii plus 383. Price, 16s.

THE scope of this specialized dictionary may be adequately described by the following sentence taken from the preface. The subjects selected for treatment are Biology and its allies, Anatomy, Botany, Zoology, Embryology, Cytology, Physiology; some terms in Bacteriology and Palaeontology are included.

It is more than a bare list of definitions because the roots of each word are given, and this makes it much more valuable as it enables the student to acquire an intelligent conception of the real meanings of the words, and on this account to remember them more easily.

This is a book that students of any of the above subjects would be well advised to have constantly within easy reach on their desks, because in it will be found many terms that are not in an ordinary dictionary and a large dictionary or encyclopædia is unsuitable for this purpose on the grounds of bulk and the fact that they are too expensive for the average student.

MEDICAL ORGANIZATION AND SURGICAL PRACTICE IN AIR RAIDS.—By P. H. Mitchiner, C.B.E., T.D., M.D., M.S., F.R.C.S., and E. M. Cowell, D.S.O., T.D., M.D., B.S., F.R.C.S. 1939. J. and A. Churchill, Limited, London. Pp. viii plus 247, with 50 illustrations, including 1 coloured plate. Price, 10s. 6d.

WITH war-clouds hanging over Europe, almost every government is busy with organization of anti-air-raid precautions and measures for medical relief of victims of future air raids. The authors are to be congratulated on this timely publication dealing with organization of medical relief and surgical practice in air raids. Both Mr. Mitchiner and Colonel Cowell had considerable experience of surgery during the Great War, and Colonel Cowell went to Spain in December 1938 to acquire first-hand information on modern air raid casualties. The members of the medical profession 'who have fortunately been spared the experience of war', have the benefit of the accumulated experience of the authors in this valuable book.

The details of organization and administration of different units in medical relief, namely first-aid parties, dressing stations, casualty clearing hospitals, base hospitals, etc., have been dealt with in one chapter. These are based on the scheme as envisaged by the British Ministry of Health. The chapter on air attack, its methods and the effects of aerial bombardment, and the methods of protection from air attack make particularly interesting reading. The authors have dealt with the treatment of different types of wounds and their complications briefly, stressing the difference in technique that exists between civil and air raid practice. The various injuries that may be inflicted on different parts of the body during air raids have been adequately dealt with.

There are numerous excellent illustrations showing the various types of injury caused during air raids, and their treatment. A photograph of spreading cutaneous gas gangrene starting in an infected appendectomy wound, however, does not fall into the category of injury (or its complications) caused by air raids.

A chapter has been devoted to organization of nursing, and appendices deal with first aid and transport, chemical warfare, details of equipment of mobile surgical units and x-ray units.

The book will be found valuable by members of the medical profession engaged in A. R. P. work, as also by those engaged in nursing, or first aid work.

THE MORPHOLOGY OF THE BRACHIAL PLEXUS—WITH A NOTE ON THE PECTORAL MUSCLE AND ITS TENDON TWIST.—By W. Harris, M.D., F.R.C.P. 1939. Oxford University Press, London; Humphrey Milford. Pp. xviii plus 117. Illustrated. Price, 25s. Obtainable from Oxford University Press, Bombay and Calcutta

THIS is an interesting work on the comparative anatomy of a very important nerve plexus with a short account of the pectoralis major muscle, which gives a new conception of the variations noted in the muscle in different types of animal, depending on the different functions it is called upon to perform.

It is an extremely painstaking effort which has spread over 37 years and is a tribute to the energy and enthusiasm of the author, because the immense amount of work it has entailed, containing as it does

the results of dissections on 158 animals ranging from amphibia to man, has been carried out in the intervals of a busy professional life as a physician.

It is a valuable study in comparative anatomy showing as it does the variation in the nerve roots which supply trunks to the brachial plexus, and that this is very largely dependent on other anatomical differences such as the different number of cervical vertebrae in different types of animal, and as such it is a distinct contribution to anatomical knowledge.

The illustrations are numerous, clear and well produced and the book is printed on heavy art paper, which is not a disadvantage in a comparatively small book, as the weight is not inconvenient.

It should prove of value to all professional anatomists.

TEXTBOOK OF MEDICINE.—By Various Authors. Edited by J. J. Conybeare, M.C., D.M. (Oxon.), F.R.C.P. Fourth Edition. 1939. E. and S. Livingston, Edinburgh. Pp. xx plus 1112. Illustrated. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 14

DR. CONYBEARE'S book does not need any introduction to the medical profession. It is one of the books which has given innumerable medical students of the last ten years their basic knowledge of medicine.

In this edition, a number of valuable additions have been made. The chief of these is a section on psychological medicine including the psychoses and the psycho-neuroses. This has led to the addition of about a hundred pages to the book. Several chapters have been rewritten in the light of recent advances, and several chapters on recently recognized clinical entities have been added. These improvements have further enhanced the value of an already excellent book.

The reviewer has but a few criticisms to make. As this book is read by medical students and practitioners in the tropics, it is desirable that the section dealing with the tropical diseases should be more comprehensive. Thirty-four pages allotted to this subject is too meagre, and this has led to inadequate description of important tropical diseases.

Certain recent advances in therapeutics have not been mentioned, e.g., M. & B. 693 in pneumonia, nicotinic acid or vitamin-B concentrates in pellagra, trichlorethylene in trigeminal neuralgia, ergotamine tartrate in migraine. It is nowadays not correct to say that 'ultimate outlook is poor' in the case of pellagra. Early and moderately advanced cases respond rapidly to specific treatment and relapse can be prevented by adding vitamin-B concentrates to the diet.

The get-up, printing and illustrations are excellent and reflect credit on the publishers.

The book will be found extremely valuable by medical students and general practitioners.

P. C. S. G.

AIDS TO FORENSIC MEDICINE AND TOXICOLOGY.

—By W. G. Atchison Robertson, M.D., D.Sc., F.R.C.P.E. Eleventh Edition. Edited by J. H. Ryffel, B.Ch., B.Sc. 1939. Baillière, Tindall and Cox, London. Pp. x plus 170

THAT it takes a great man to write a small book on a big subject could not be better exemplified than by this little book. Generations of medical students are indebted to two great men who gave them the distilled essence of forensic medicine in ten editions and thus created in them the confidence necessary for embarking on a study which can be and is vast indeed. The present writer also has done his best in the eleventh edition.

Opinion in a nut-shell is given on many topics, for example:—(i) if a child dies immediately after birth it is almost impossible to prove that it was born alive; (ii) it is not flattering to one's vanity to overlook a case of malingering, but should this occur little harm is done; and (iii) there is no practical advantage [for forensic purposes] in attempting to classify the different forms of insanity.

Treatment of toxicology is as complete as that of forensic medicine and includes the latest information on the poison rules. Essential information is available on poisonous fungi, which is often lacking in much bigger books, and on stimulating drugs. The use of types M & N in blood groups, in determining illegitimacy, is indicated.

The reviewer offers a few suggestions for the revision of the text in the next edition. M & N are 'types' not 'groups' and the animal used in preparing the anti-fluid for determining them is 'immunized' not 'activated'. Typhoid, para-typhoid and dysentery organisms may occur in food as a source of infection but they are not responsible for food poisoning. On page 77, para 1, line 5, 'associated' should be 'associate'; para 2, line 5, 'and vice versa' is obviously not required.

The paper, the size, the printing and the binding are good. The price, if it is the same as that of the tenth edition, namely 3s. 6d., is very reasonable. The book should be read by all interested in forensic medicine.

S. D. S. G.

SELECTED PICTURES OF EXTRA-OCULAR AFFECTIONS FROM THE MUSEUM OF THE GOVERNMENT OPHTHALMIC HOSPITAL, MADRAS, WITH EXPLANATORY NOTES FOR STUDENTS AND POST-GRADUATES.—By Lieut.-Colonel R. E. Wright, C.I.E., M.D., D.P.H., I.M.S. 1938. Government Press, Madras. Pp. 41 plus 48. Illustrated. Price, Rs. 2

LIEUTENANT-COLONEL WRIGHT and Dr. Koman Nayar have published in ingenious form a collection of stereoscopic pictures of extra-ocular affections, rendering generally accessible the best of the photographs which are to be seen in the stereoscope in the Elliot School of Ophthalmology in Madras.

While on a recent visit to Madras, the reviewer noticed how this valuable collection was deteriorating from the effects of the climate, and it is pleasant to know that by the publication of this folio a permanent record has now been made.

The pictures are rendered stereoscopic by looking at them through a pair of +6D spheres adjusted in a trial frame. The folio is so arranged as to permit simultaneous access to the notes which describe each picture.

This book should have a special appeal to post-graduate students in ophthalmology, and should find a place in the library of every medical school.

W. McN. N.

CLASSIC DESCRIPTIONS OF DISEASE WITH BIOGRAPHICAL SKETCHES OF THE AUTHORS.

By Ralph H. Major, M.D. Second Edition. 1939. Published by Charles C. Thomas, Springfield, Illinois. Pp. xxx plus 727. Illustrated. Price, 27s. Obtainable from Messrs. Baillière, Tindall and Cox, London

THE title of this book is a modest one for it is much more than 'Classic Descriptions of Disease', as it contains very many reproductions of portraits or photographs of the masters of medicine, and reproductions of title pages of famous ancient medical books and other interesting historical illustrations. There is also a brief but comprehensive biographical note on each of the masters as an introduction to the description of the disease for which he is famous. This method of presentation greatly adds to the vividness of the description, because with the biographical sketch fresh in one's mind one almost feels the man himself is speaking.

Descriptions of malaria and yellow fever have been included in this edition, both of which will add to the interest and value of the book to workers in the tropics.

It is a book that should be of great benefit to the student towards the end of his studies and it should also be a source of constant pleasure and valuable information to the practising physician and surgeon.

The volume is well bound and is printed on heavy art paper a fact which provides the reviewer's only criticism, and that is that it makes the book rather heavy to hold. This is a pity as it is essentially a book to read in an easy chair.

ACTINOTHERAPY AND DIATHERMY FOR THE STUDENT.—By E. B. Clayton, M.B., B.Ch. (Cantab.). 1939. Baillière, Tindall and Cox, London. Pp. viii plus 182. Illustrated. Price, 7s. 6d.

This little book is written for students preparing for the examinations of the Chartered Society of Massage and Medical Gymnastics. It is founded on the author's lecture notes and includes sections on short-wave diathermy and inductothermy.

It is divided into two parts—Part I—Light. Part II—Diathermy. Both sections are introduced by chapters on physics. There are sections on physiological effects, value in disease and technique of application.

The arrangement of subjects is logical and the phraseology lucid.

It is a book which should prove of value not only to the student, but to the general practitioner who is interested in these subjects.

J. A. S.

DIET AND ILL-HEALTH IN THE FOREST COUNTRY OF THE GOLD COAST.—By F. M. Purcell, M.D. (Dublin University), M.R.C.P. (Ireland), D.T.M. & H. (London). 1939. H. K. Lewis and Company, Limited, London. Pp. viii plus 77, with 62 illustrations. Price, 7s. 6d.

The author describes this small book as a 'paper' and this is a more or less correct definition because it is by no means a finished presentation of the subject.

It is composed of two parts. Part I is devoted to a brief description of the general physical characters of certain tribes in the Gold Coast and the diets they consume. This is necessarily incomplete as proper analysis of the various foods has not yet been undertaken.

Part II describes in brief, certain syndromes which on presumptive evidence are considered to be caused by dietetic deficiencies, and notes on illustrative cases are given.

The publication is only in the nature of a preliminary report on conditions in a part of West Africa and as such is of little interest elsewhere; but if it is followed by a better arranged and documented book it should be a useful addition to the subject of nutrition in general.

BRITISH MEDICAL SOCIETIES.—Edited by Sir D'Arcy Power, K.B.E., F.R.C.S. 1939. Published by the Medical Press and Circular, London. Pp. xvi plus 312. Illustrated. Obtainable from Messrs. Baillière, Tindall and Cox, London. Price, 10s. 6d.

The book gives brief histories of thirty-four medical societies in the British Isles. They are arranged in chronological order beginning with the Society of Apothecaries of London, 1617, and ending with the Kensington Medical Society, 1925.

It actually includes a good many more societies than thirty-four because in the course of their evolution many of them have changed their names or have become amalgamated with others. Each account is contributed by a different writer, usually one who has held or holds office in the executive of the society concerned, and they have been collected and edited by Sir d'Arcy Power whose special contribution is the history of the Abernethian Society.

These papers originally appeared in the *Medical Press and Circular* in the years 1936-1938 but collecting them into a single volume presents them in a handier form for preservation than scattered through the issues of a journal for three years, and as such makes a valuable addition to the history of medicine in the British Isles.

P. A. M.

BRITISH HEALTH RESORTS. 1939 Edition. Published by British Health Resorts Association Limited, Tavistock House (South), Tavistock Square, W.C.1.

This year the book is, for the first time, the property of the Association.

The information has been carefully revised and brought up to date. Those interested in medical climatology will find some new tables dealing with the 'Invalid's Winter on the Coast', followed by a general discussion of the British climate in winter (pp. 149 to 157).

The descriptions of the spas have been carefully revised as a result of visits recently carried out.

In the present state of uncertainty in Europe this publication is of even greater interest than formerly because few Englishmen would be prepared at present to visit the well-known spas on the continent, and in this book they can learn where they can obtain equally good health resorts in their own country.

AN INTRODUCTORY GUIDE TO BIOCHEMISTRY.—By S. Bilss, Ph.D. 1939. W. B. Saunders Company, Philadelphia and London. Pp. 103. Price, 5s. 6d.

The aim of this small book is stated to be to introduce the various divisions of the subject of biochemistry through a greatly simplified statement of them and thus avoid frightening the beginner with an extensive array of what at first appears incomprehensible and complicated graphic formulas.

The author has succeeded admirably, and in expressing this view the reviewer speaks feelingly, because he qualified in the days when a few lectures on organic chemistry, as an appendix to the ordinary preliminary chemistry instruction, were all that the student was told of the then practically unknown subject of biochemistry. The result of this is that in subsequent years he has painfully acquired a smattering of the subject in its modern form. Had such a book as this one been available it would have saved him many hours of reading to find out the meaning of many of the terms now employed, and his more recently trained colleagues the trouble of answering innumerable questions.

It is a book that a student would be well advised to read before embarking on the study of biochemistry.

Abstracts from Report

SEVENTY-SIXTH ANNUAL REPORT OF THE GOVERNMENT CINCHONA PLANTATIONS AND FACTORY IN BENGAL FOR THE YEAR 1937-38

The market prices of quinine salts continued to be steady during the year. Imports, which had been falling off for some time past, showed signs of rallying, in spite of the increased consumption of Indian cinchona products. This may mean merely an improvement in general trade conditions or else an increasing faith in quinine. Considering, however, the incidence of malaria in the country, it is surprising how small the consumption really is, being scarcely a third of the estimated requirements.

The solution of the problem depends obviously on a greatly extended production within the country, leading ultimately to a cheapening of the drug. Public attention has been focussed on the subject for a number of years. An enquiry was started in the latter half of the year, under the auspices of the Imperial Council of Agricultural Research, with a view to discovering new areas suitable for the cultivation of cinchona. Mr. A. Wilson, the officer in charge of this enquiry, has paid two visits to the Bengal plantations. It will be anticipating matters to give particulars of his impressions and his own report must be awaited in order to obtain, in due course, his considered views.

It would not, however, be out of place here to point out that a general survey of this nature, though it must lead to valuable technical conclusions and indicate possible lines of development, would require to be followed up by further and sustained observations. After 80 years of domestication cinchona still remains a plant of very fastidious habits and depends for its well-being on a great number of climatic and soil factors the optimum limits of which are not yet definitely known. Still less do we know the details of the climatic and soil conditions prevailing in the interiors of new areas which may appear from a general examination to be either suitable or unsuitable. It seems to be advisable, therefore, that any extensive areas, which may appear to be promising from a general survey, should remain under close observation for a period before large expectations are built upon them.

The extension of the actual area under cultivation is only one of the factors, though perhaps the main factor, in the problem of extended production. Auxiliary factors are (1) increasing the productivity of the land in respect of bark, and (2) improving the quality of the bark in respect of its content of the alkaloids. The first of these depends on improved methods of cultivation, the adoption of a cycle of operations suited to each individual region, and the application of suitable methods of soil rejuvenation after the successive cycles of cinchona. It would be a very unwise policy to concentrate on the extent of area alone and depend on rapid methods of exploitation. For, even assuming that land were plentiful, the cost of production would be kept within reasonable limits only if a given area could be made to yield the maximum possible result in order to reduce the incidence of overhead expenses and the heavy capital layout in opening up land and constructing buildings, roads and bridges.

The second auxiliary factor, namely, the content of alkaloids in the bark, is undoubtedly of the greatest importance in the problem of increasing production, for even a rise of one per cent in the quinine content of bark—our present average being 4 per cent—would lead to an increase of 25 per cent in production. An intensive programme of work in this direction, combining both biological and chemical investigations, should produce material results at a comparatively moderate expense.

Bengal is one of the provinces most seriously affected by malaria. It has been fortunate in its success up to date in establishing a cinchona industry. But it is less fortunate in that, owing to its geographical situation and general topographical features, there is not much likelihood of any great extent of fresh land being available for extension. The problems of improving the productivity of the land and the quality of the product are therefore of particular importance at this juncture. A well-planned programme of research, both in the laboratory and the field, is urgently called for.

The factory continued to work at full pressure throughout the year. Besides the extraction of bark and the preparation of quinine sulphate of various grades, numerous subsidiary salts and the usual variety of tablets were manufactured.

The total quantity of bark extracted during the year was 1,236,996 lb. This is a reduction of 12 per cent on the previous year and was due to the falling off in supplies from the plantations. The high quinine contents of the previous year were not maintained, Munson bark having an average of 4.43 per cent, Mungpoo bark 3.73 per cent and India bark 3.94 per cent as compared with the previous figures of 4.7, 4.08 and 4.92 respectively. The present figures correspond, however, to the percentages obtained in 1935-36.

Of the quinine sulphate from Indian bark 3,264 lb. were obtained in purified form, the balance of 1,159 lb. being left in the crude state. Of the yield from Bengal bark 13,030 lb. were left in the crude state and 29,361 lb. were purified to the Government standard. A further quantity of 6,622 lb. of this standard was prepared from bin stocks and other sources in order to cope with the demand for this product. Quinine

sulphate of B.P. standard was also prepared to the extent of 14,011 lb. The agency scheme which started towards the end of the previous working year got into full stride during the year under review. Demand was up to the yearly quantities agreed upon for supply, and the factory was kept fully occupied with the preparation of several high grade salts, both in powder and tablet form and in a great variety of packings.

The conversion of quinine sulphate to other salts shows a total of 1,327 lb. of which the hydrochloride and bishydrochloride, both B.P. standard and the ordinary standard, accounted for 1,249 lb., the balance being bisulphate, hydrobromide, bishydrobromide, salicylate and tannate.

There was a marked increase in the activity of the tablet department, a total of 23,407 lb. of products of all kinds being converted as against 12,380 lb. only in the previous year. In consequence, this department had to be run overtime at night for a considerable period of the year. A new line was reinforced cinchona febrifuge tablet, prepared from a mixture of cinchona febrifuge and quinine sulphate, for the Government of Assam. The quantities of different products converted into tablets were:—

Quinine sulphate, B.P.	..	185 lb.
Quinine sulphate, Government standard	14,154 "	
Quinine sulphate, crude	..	2,932 "
Cinchona febrifuge	..	3,924 "
Reinforced cinchona febrifuge	..	1,038 "
Other quinine salts	..	175 "
TOTAL	..	22,408 lb.

There was a considerable increase of activity in the laboratory also. Investigations were in progress on the continued improvement of the quality of products and of the efficiency of manufacturing processes. Over three hundred samples from the plantation were analysed in connection with cultural and valuation problems. In addition to numerous qualitative tests on the final products and intermediates, nearly sixteen hundred quantitative analyses were made during the year. All this work and the commencement of some essential enquiries, which had to be held over before, were facilitated by the inclusion of two new technical officers in the factory staff.

Service Notes

APPOINTMENTS AND TRANSFERS

BREVET-COLONEL B. C. ASHTON to be O. C., C. I. M. H., Dehra Dun. Dated 17th May, 1939.

Lieutenant-Colonel M. L. Dhawan to be Officer-in-Charge, I. H. C. Records, Kirkee. Dated 6th May, 1939.

Lieutenant-Colonel J. E. Ainsley to be O. C., I. M. H., Karachi. Dated 17th May, 1939.

Lieutenant-Colonel J. H. Smith, Civil Surgeon, Maymyo, made over, and Lieutenant-Colonel R. C. Phelps received charge of the duties of Civil Surgeon, Maymyo, on the afternoon of the 12th May, 1939.

Lieutenant-Colonel R. C. Phelps, Medical Superintendent, General Hospital, Rangoon, on transfer, made over, and Lieutenant-Colonel A. Ba Thaw received charge of the duties of the Medical Superintendent, General Hospital, Rangoon, on the forenoon of the 11th May, 1939.

Lieutenant-Colonel J. H. Barrett, Civil Surgeon, Toungoo, on proceeding on leave, made over, and Captain H. Min Sein received charge of the duties of the Civil Surgeon, Toungoo, on the afternoon of the 11th May, 1939.

Lieutenant-Colonel D. R. Thomas, O.B.E., Chemical Examiner to Government, Punjab, has been deputed to the Chemical Warfare School, India, Belgium, for training in Air Raid Precautions from the 14th May, 1939.

Lieutenant-Colonel P. B. Bharucha, O.B.E., D.S.O., Principal and Professor of Surgery, King Edward Medical College, Lahore, appointed to officiate as Inspector-General of Civil Hospitals, Punjab, in the leave vacancy of Colonel G. G. Jolly, C.I.E., V.H.S., from the 12th May, 1939.

Lieutenant-Colonel A. M. Dick, C.B.E., V.H.S., Professor of Ophthalmic Surgery, appointed to officiate as Principal, King Edward Medical College, Lahore, in addition to his own duties from the 12th May, 1939.

Lieutenant-Colonel V. R. Mirajkar, O.B.E., Professor of Operative Surgery, appointed to officiate as Professor of Surgery, King Edward Medical College, Lahore, *vice* Lieutenant-Colonel P. B. Bharucha, O.B.E., D.S.O., from the 12th May, 1939.

Lieutenant-Colonel N. D. Puri, Deputy Inspector-General of Prisons, Punjab, appointed to officiate as Inspector-General of Prisons, Punjab, with effect from the 17th May, 1939, *vice* Lieutenant-Colonel F. A. Barker, C.I.E., O.B.E., granted leave.

Lieutenant-Colonel P. D. Chopra, Superintendent, New Central Jail, Multan, appointed to officiate as Deputy Inspector-General of Prisons, from the 17th May, 1939, *vice* Lieutenant-Colonel N. D. Puri.

Lieutenant-Colonel G. D. Malhontra, Civil Surgeon, from Shahjahanpur to Sitapur.

The services of Lieutenant-Colonel T. C. Boyd, Officiating Surgeon-General with the Government of Bengal, are placed at the disposal of the Government of the United Provinces, with effect from the 10th June, 1939.

Major B. S. Nat, Professor of Anatomy, appointed to officiate as Professor of Operative Surgery, King Edward Medical College, Lahore, *vice* Lieutenant-Colonel V. R. Mirajkar, O.B.E., from the 12th May, 1939.

Major J. J. Beausang, Civil Surgeon, Sargodha, posted as Civil Surgeon, Amritsar, from the 11th May, 1939, *vice* Lieutenant-Colonel P. A. Dargan, granted leave.

Major J. McM. Wilder to be Officiating O. C., I. M. H., Jubbulpore. Dated 17th April, 1939.

Major N. J. U. Mather to be specialist in Mental Diseases, Western India District. Dated 19th May, 1939.

Major T. A. Malone to be attached officer, Medical Directorate, Army Headquarters. Dated 27th May, 1939.

Major E. S. S. Lucas, Civil Surgeon, Moradabad, from the 14th May, 1939.

Major W. Lawie, Civil Surgeon, from Agra to Bareilly, *vice* Major R. A. Wesson, granted leave.

As a temporary measure Major A. N. Chopra, Assistant Director-General, I. M. S., is appointed Officer-in-Charge, Medical Store Depot, Lahore Cantonment, with effect from the forenoon of the 24th April, 1939, on which date he took over charge of the Depot, from 1st class Assistant Surgeon E. Duckworth, M.B.E.

Major K. S. Fitch made over charge of the Burdwan Jail to Dr. K. C. Sen Gupta on the forenoon of the 15th May, 1939.

In modification of previous Notification Major F. H. Whyte is appointed to the post of Civil Surgeon, Simla West, with effect from the forenoon of the 15th April, 1939.

Captain F. C. Leach, Superintendent, Mental Hospital, Nagpur, and Civil Surgeon and Superintendent, Robertson Medical School, Nagpur, ceased to be Superintendent, Mental Hospital, Nagpur, with effect from the 16th May, 1939.

Captain M. Sendak, Civil Surgeon, Saugor, has been transferred as Senior Medical Officer, Port Blair.

Captain T. F. O'Donnell, whose services have been placed temporarily at the disposal of the U. P. Government for Civil employ on completion of three weeks' training, has been posted as Civil Surgeon, Jhansi, with effect from the 6th May, 1939.

Captain J. D. Murdoch was transferred to civil employ as Superintendent, Medical School, and Civil Surgeon, Cuttack. Dated 9th May, 1939.

Captain T. F. O'Donnell, Civil Surgeon, Jhansi, with effect from the 6th May, 1939.

Captain Sadi Ahmad, Civil Surgeon, from Sitapur to Agra, *vice* Major W. Lawie, transferred.

Captain W. T. Taylor, on relinquishing charge of the Medical Store Depot, Lahore Cantonment, is appointed as Officer-in-Charge, Medical Store Depot, Madras, with effect from the forenoon of the 20th April, 1939, relieving Captain D. M. Frost.

Captain A. H. Barzilay to be Staff Captain (Medical), Western India District. Dated 25th April, 1939.

Captain P. N. Bardhan to be Officer-in-Charge, Brigade Laboratory, Jhansi. Dated 8th May, 1939.

Captain L. U. Kamm to be Officiating O. C., I. M. H., Aurangabad. Dated 27th May, 1939.

The undermentioned short service I. M. S. Officers have been granted permanent commissions from the dates noted opposite their names:—

Captain B. N. Bhandari. Dated 21st May, 1939.

Captain B. L. Kapur. Dated 22nd May, 1939.

Captain P. M. Kaul. Dated 26th May, 1939.

The undermentioned short service I. M. S. Officers have been released from the service from the dates noted:—

Captain M. L. Gujral. Dated 19th May, 1939.

Captain Mohan Singh. Dated 21st May, 1939.

Captain D. R. Sharma. Dated 23rd May, 1939.

Captain G. N. Ahmadi. Dated 25th May, 1939.

Captain P. S. Bassalvi. Dated 25th May, 1939.

To be Captains (on probation)

Baij Nath Bhandari. Dated 21st May, 1939, with seniority from 21st May, 1935.

Behari Lal Kapur. Dated 22nd May, 1939, with seniority from 22nd May, 1935.

Prince Mohan Kaul. Dated 26th May, 1939, with seniority from 26th May, 1935.

The undermentioned Officers arrived in Bombay on first appointment on the dates shown opposite their names:—

Captain V. D'A. Blackburn. Dated 5th May, 1939.

Lieutenant L. E. Elkerton. Dated 28th April, 1939.

Lieutenant C. C. Harvey. Dated 24th May, 1939.

Lieutenant L. H. Cooper. Dated 12th May, 1939.

Lieutenant J. A. M. Cameron. Dated 12th May, 1939.

Lieutenant W. S. Hacon. Dated 12th May, 1939.

Lieutenant A. M. Best. Dated 12th May, 1939.

Lieutenant R. J. McGill. Dated 12th May, 1939.

Lieutenant J. Lightbody. Dated 12th May, 1939.

Lieutenant D. F. Eastcott. Dated 12th May, 1939.

Lieutenant H. F. T. MacFetridge. Dated 12th May, 1939.

To be Lieutenants

Sailendra Mohan Basu. Dated 17th March, 1939.

Amar Nath Roy. Dated 20th March, 1939.

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the undermentioned Officers of the Indian Medical Service with effect from the 1st April, 1937. These Officers will count their seniority in civil employment with effect from the dates noted against their names, being the dates on which they joined civil employment:—

Government of India

Major H. W. Farrell. Dated 12th May, 1934 (afternoon).

Captain G. K. Graham. Dated 5th November, 1934.

Major B. Chaudhuri. Dated 18th April, 1935 (afternoon).

Major W. D. B. Read. Dated 12th June, 1935.

Captain W. J. Moody. Dated 30th June, 1935 (afternoon).

Captain M. Jafar. Dated 4th July, 1935.

Captain R. D. McRae. Dated 3rd September, 1935 (afternoon).

Lieutenant-Colonel A. D. Loganadan. Dated 9th September, 1935.

Major A. N. Chopra. Dated 8th November, 1935 (afternoon).

Captain J. R. Dogra. Dated 16th November, 1935.

Major C. K. Lakshmanan. Dated 16th December, 1935.
 Captain C. J. H. Bink. Dated 23rd December, 1935.
 Major M. K. Afridi. Dated 4th January, 1936.
 Major K. H. A. Gross, M.C. Dated 19th April, 1936 (afternoon).
 Captain E. A. O'Connor. Dated 22nd October, 1936.
 Captain J. Guthrie. Dated 9th March, 1937.

Madras

Major F. M. Collins. Dated 30th October, 1934.
 Captain J. S. McMillan, C.M. Dated 15th November, 1934.
 Captain R. L. Haviland Minchin. Dated 30th April, 1936.
 Captain F. A. B. Sheppard. Dated 3rd September, 1936.
 Major P. V. Karamchandani. Dated 29th September, 1936.
 Major S. T. Davies. Dated 7th December, 1936.
 Major Lakshman Dass. Dated 30th January, 1937.
 Lieutenant-Colonel S. C. Alagappan. Dated 20th February, 1937.

Bombay

Captain B. S. Sandhu. Dated 1st June, 1935.
 Captain R. DeSoldenhof. Dated 3rd February, 1937.

Bengal

Lieutenant-Colonel B. G. Mallaya. Dated 3rd July, 1923.
 Lieutenant-Colonel B. H. Singh. Dated 12th May, 1925.
 Lieutenant-Colonel P. C. Banerjee. Dated 13th May, 1925, since retired.
 Major T. H. Thomas. Dated 30th September, 1927.
 Major C. L. Pasricha. Dated 1st January, 1929.
 Lieutenant-Colonel S. Nag. Dated 1st July, 1931.
 Major D. C. Drummond. Dated 15th February, 1932.
 Major R. Linton. Dated 14th April, 1932.
 Major K. S. Fitch. Dated 26th May, 1934.
 Major E. G. Montgomery. Dated 7th June, 1934 (afternoon).
 Captain G. B. Fisher. Dated 11th June, 1934.
 Major G. Kelly. Dated 13th July, 1934.
 Captain F. H. A. L. Davidson. Dated 1st November, 1934.
 Captain E. H. Lossing. Dated 12th June, 1936.
 Captain F. W. Allinson. Dated 16th November, 1936.

United Provinces

Lieutenant-Colonel J. C. Bharucha. Dated 19th April, 1923.
 Major G. D. Malhoutra. Dated 21st June, 1934 (afternoon).
 Captain M. R. Sinclair, O.B.E. Dated 26th June, 1935.
 Major S. C. H. Worleline. Dated 16th October, 1936.
 Major R. K. Misra. Dated 2nd January, 1937.
 Captain Said Ahmad. Dated 15th February, 1937.
 Captain J. H. Boulton. Dated 19th March, 1937.

Punjab

Captain B. Temple Raston. Dated 15th March, 1935.
 Captain P. C. Dutta. Dated 10th October, 1935.
 Major J. J. Beausang. Dated 22nd April, 1936.
 Captain J. P. J. Little. Dated 30th August, 1936.
 Captain Ilahi Bakhsh. Dated 25th September, 1936 (afternoon).
 Major G. F. Taylor. Dated 1st October, 1936.
 Lieutenant-Colonel W. Ross Stewart, C.I.E. Dated 10th February, 1937.

Bihar

Major M. S. Gupta. Dated 3rd July, 1934.
 Captain D. P. Nath. Dated 28th April, 1935.
 Captain R. T. Hicks. Dated 8th October, 1935.
 Lieutenant-Colonel G. H. Mahony. Dated 9th October, 1935.
 Captain H. J. Curran. Dated 7th May, 1936 (afternoon).
 Captain A. W. West. Dated 22nd June, 1936.

Central Provinces and Berar

Lieutenant-Colonel J. M. R. Hennessy. Dated 4th May, 1924.

Captain V. Srinivasan. Dated 22nd February, 1937.

Assam

Lieutenant-Colonel E. T. N. Taylor. Dated 29th June, 1936.

North-West Frontier Province

Lieutenant-Colonel P. H. S. Smith, O.B.E. Dated 1st November, 1932.

Captain H. D. R. Zscherpel. Dated 15th March, 1933.

Captain H. H. Mahmood. Dated 18th March, 1935.
 The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the following Officers of the Indian Medical Service with effect from the dates stated against their names:—

Government of India

Captain M. H. Shah. Dated 15th April, 1937.
 Colonel E. G. Kennedy. Dated 30th June, 1937.
 Captain F. M. Khan. Dated 14th September, 1937.
 Captain J. D. Grant. Dated 12th November, 1937.

Madras

Captain J. Eddis-Myres. Dated 1st July, 1937.
 Major E. M. Sewell. Dated 28th October, 1937.
 Captain W. Ilapper. Dated 24th December, 1937.

Bombay

Captain A. A. Pillar. Dated 7th July, 1937.
 Captain C. B. Miller. Dated 6th August, 1937.

Bengal

Major S. Annaswami. Dated 3rd April, 1937.

Bihar

Captain A. C. Taylor. Dated 8th July, 1937.
 Major deL. Carey. Dated 20th November, 1937.

LEAVE

Colonel F. F. S. Smith, A. D. M. S., Peshawar District, proceeded on 5 months' combined leave *ex-India* from 27th April, 1939.

Colonel W. A. M. Jack, O.B.E., O. C., I. M. H., Rawalpindi, sailed from Bombay per S.S. *Viceroy of India* on 6 months' leave on medical certificate on 13th May, 1939.

The following Officers have proceeded on leave with effect from the dates mentioned:—

Colonel G. G. Jolly, C.I.E., 3 months and 15 days *ex-India* from the 12th May, 1939.

Lieutenant-Colonel P. A. Dargan, 7 months *ex-India* from the 9th May, 1939.

Lieutenant-Colonel S. N. Hayes, 15 days *ex-India* from the 1st June, 1939, with permission to affix thereto the College vacation from the 16th June, 1939, to 30th September, 1939.

Lieutenant-Colonel F. A. Barker, C.I.E., O.B.E., leave *ex-India* from the 17th May, 1939, to 16th October, 1939, preparatory to retirement.

Lieutenant-Colonel J. P. Cantenwala, Officer-in-Charge, Medical Store Depot, Madras, is granted 8 months' leave, with effect from the 28th February, 1939, the first 2 months being privilege leave and the rest on medical certificate.

Lieutenant-Colonel S. A. Phatak, I. M. H., Bangalore, proceeded on 6 months' combined leave in India pending retirement. Dated 24th April, 1939.

Lieutenant-Colonel R. S. Aspinall, C.I.E., an Agency Surgeon, is granted leave on average pay for 3 months under the Fundamental Rule, with effect from the forenoon of the 6th May, 1939.

Lieutenant-Colonel J. H. Barrett was granted 4 months and 21 days' leave on average pay preparatory to retirement from the afternoon of the 11th May, 1939.

Lieutenant-Colonel F. J. Anderson, Professor of Surgery, Medical College, Calcutta, is granted leave *ex-India* for 2 months, with effect from the 18th May, 1939.

The undermentioned Officers proceeded on privilege leave *ex-India*, pending resignation, from the dates noted opposite their names:—

Captain N. P. Woodgate-Jones. Dated 10th May, 1939.

Captain J. W. Richmond. Dated 26th May, 1939.
 Captain J. H. Briscoe-Smith. Dated 5th May, 1939.

PROMOTIONS

The following Officers have been promoted to the selected list of Lieutenant-Colonels with effect from the dates noted against their respective names:—

Lieutenant-Colonel W. Ross Stewart, C.I.E. Dated 31st January, 1939.

Lieutenant-Colonel H. Chand. Dated 5th March, 1939.

Majors to be Lieutenant-Colonels

J. R. Katariya. Dated 16th April, 1939.

C. V. D. Rose. Dated 25th April, 1939.

The provisional promotion to present rank of Major A. K. Gupta is confirmed.

Note.—The promotion to present rank of Major G. J. Smith notified in the late Army Department Notification No. 597, dated the 14th October, 1933, is antedated from the 7th October, 1933, to 7th April, 1933. He qualified for accelerated promotion on 25th January, 1939.

Captains to be Majors

Ilahi Bakhsh. Dated 8th April, 1939.

R. T. Hicks. Dated 22nd April, 1939.

A. M. Sheridan. Dated 29th April, 1939.

Lieutenants (on probation) to be Captains (on probation)

E. J. Somerset. Dated 12th March, 1939, with seniority from 1st May, 1938.

L. D. B. Frost. Dated 12th March, 1939, with seniority from 1st May, 1938.

A. M. Mackenzie. Dated 12th March, 1939, with seniority from 1st May, 1938.

R. M. McCullough. Dated 12th March, 1939, with seniority from 1st November, 1938.

H. V. Morris. Dated 12th March, 1939, with seniority from 1st November, 1938.

F. W. Snedden. Dated 12th March, 1939, with seniority from 1st November, 1938.

J. L. M. Whitbread. Dated 12th March, 1939, with seniority from 1st November, 1938.

Lieutenant S. M. Basu was appointed to a short service commission from 17th March, 1939, and promoted to Captain from same date with seniority from 4th January, 1938.

RELINQUISHMENTS

Lieutenant-Colonel A. Ba Thaw relinquished charge of his duties as Assistant Inspector-General of Civil Hospitals, Burma, on the afternoon of the 10th May, 1939.

Lieutenant (on probation) R. N. Houlding relinquished his probationary appointment, 29th March, 1939.

Flight-Lieutenant Vivian D'Arcy Blackburn relinquishes his commission on appointment to a commission in the Indian Medical Service, 11th April, 1939.

Notes

VEGANIN

THE subject of pain is always with the physician, commanding his interest, both in its physiological and psychological aspects and especially in the challenging problem as to how he may appreciate its diagnostic significance, pay due heed to its warnings, and mobilize available resources for its relief and conquest.

Anatomists and physiologists, surgeons and psychologists and many clinical observers among general practitioners, are all making their contribution to-day to the investigation and alleviation of pain.

To the physician pain is but a symptom, an alarm signal; but to the patient it is an affliction that is very real and which demands early relief. The type of pain, its location, distribution, and time of occurrence; all these have a diagnostic significance, but once they have served as a guide, to let pain continue unrelieved is to give it a free rein in causing suffering and disability.

A number of analgesics have been placed in the hands of doctors by manufacturers for the prevention and alleviation of pain; but one that has been the subject of high commendation in medical and dental journals, in Great Britain and other parts of the world, is Veganin.

The manufacturers are Messrs. William R. Warner and Co., Ltd., of London, who state that 'Veganin is a dependable, safe and highly effective analgesic, sedative and antipyretic with marked antispasmodic properties'.

Veganin is presented in the form of tablets which are prepared by a special process that ensures rapid disintegration, ready utilization and prompt therapeutic action. It is claimed that the administration of Veganin is free from elements of danger, and the preparation, therefore, provides a welcome substitute for the barbiturates.

The manufacturers further state that 'Veganin can be used for the relief of pain and its nervous manifestations in a large number of conditions; and in febrile conditions its administration results in early remission of the temperature. Its use as an analgesic in absence of fever leaves the temperature unaffected'.

THE 48TH CHEMISTS' EXHIBITION, LONDON

THE Chemists' Exhibition in London is one of the most important events of the year. The 48th will be held from 18th to 22nd September next in the famous Royal Albert Hall. The management, 'The British and Colonial Pharmacist', is always pleased to welcome members of the drug trade from Overseas and they are admitted on presentation of business card. Solely for the trade, it reflects the advance in the previous 12 months.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

RAT-BITE FEVER IN CALCUTTA

By R. N. CHOPRA, C.I.E., K.H.P., M.A., M.D.,
sc.D. (Cantab.), F.R.C.P. (Lond.)

BREVET-COLONEL, I.M.S.

B. C. BASU, D.Sc.

and

S. SEN, M.B., D.T.M.

(From the School of Tropical Medicine, Calcutta)

ALTHOUGH rat-bite fever has been reported from different parts of the world, only about 150 cases have been recorded in the literature. The present authors have records of 455 typical cases of this disease, studied in the Carmichael Hospital for Tropical Diseases, and in the out-patient department of the School of Tropical Medicine, with observations regarding its incidence in relation to season, age, diagnosis and treatment. Experimental work has also been done with regard to the disease in animals and the course it runs in them, which will be published in a separate paper.

As rat-bite fever is not commonly met with in India a short account of this condition will not be out of place.

Rat-bite fever is primarily an affection of rats and man is infected secondarily following the bite of a rat or rarely of a weasel, ferret, squirrel, or cat. The fever is of a relapsing type, the causal organism being *Spirillum minus*. This organism has comparatively broad, pre-formed and rigid spirals about 2 to 5 μ in length; occasionally longer forms 9 to 10 μ in length are seen; the number of coils varies from 2 to 4 or even 8 or 9 in the longest forms. Flagella varying from one to seven in number are present at each end, and multiplication takes place by transverse binary fission. Carter (1887) first discovered this organism in the blood of rats in Bombay and the parasite was first discovered in man by the Japanese workers Futaki, Tikaki, Taniguchi and Osumi (1916). Usually the bite heals up and nothing further happens till 2 to 6 weeks later when the site of the bite becomes inflamed and some local lymphangitis is observed. The temperature then rises with rigors and prostration which lasts for 3 to 6 days. The recurrence of paroxysms of fever at intervals of 5 or 6 days is a characteristic feature of the disease. With each paroxysm, there may be a rash, leucocytosis and eosinophilia. The disease has been known in Japan for many years and in America it has been known for nearly a century. Crohn (1915) collected histories of 24 Japanese cases, 16 American, 8 English, 2 French, 1 Italian, and 1 Indian. Blake (1916) added 28 more cases.

From 1918 to 1927, 72 cases were reported as follows :—

England ..	12	Russia ..	2	China ..	3
France ..	8	Holland ..	2	Mexico ..	1
U. S. A. ..	8	Italian ..		Hawaii ..	1
Australia ..	2	Somaliland ..	1	Brazil ..	6
India ..	4	New Guinea ..	1	Br. Guiana ..	1
Italy ..	15	Austria ..	2	Germany ..	1
Spain ..	1	Switzerland ..	1		

Knowles and Das Gupta (1928) added another 28 cases from Calcutta during 1920-28.

During the period of five years, that is 1931 to 1936 (records for October 1931 and September 1932 were not available), 876 persons reported themselves to the out-patient department for treatment with history of rat-bite. Of these, 455 (a little over 50 per cent) developed typical symptoms of the disease. This figure is significant in view of the fact that a comparatively small percentage of the wild rats in the city of Calcutta shows infection. Exudate from the site of the bite was examined in 191 cases under dark-ground illumination and in 123 cases (64.2 per cent) actively motile *S. minus* were seen. Blood of 56 typical cases was inoculated into white mice and in 39 (69.8 per cent) was found infective. Blood from 13 cases was inoculated into young guinea-pigs and in 10 (77 per cent) infection occurred. It is worthy of note that examination of peritoneal fluid and blood of white mice and young guinea-pigs in Calcutta showed that in many cases they harboured *S. minus* in their natural condition. Precautions have, therefore, to be taken to exclude this before using them for experimental purposes.

In the remaining 195 cases, though spirilla were not discovered by any of the above methods, the clinical symptoms were typical of the disease and they also responded to the usual treatment with arsenical compounds.

So far as the seasonal incidence is concerned (see graph) the largest number of cases occurred

CHART

Seasonal incidence of 455 cases of rat-bite fever during five years (1931-36).

during the months of May and September. This shows that in Calcutta the disease was more common in hot weather. This may be due to the fact that during this period many people sleep in the open and under unprotected conditions, thus increasing the chance of a bite

from a rat. Another possibility is that the natural infection in rats during this period may be higher. These points are now under investigation.

Table I gives the incidence of the disease with regard to the age of the patients. It will be observed that the highest incidence is between the ages of 21 and 30 years and next between the ages of 31 and 40 years. In this series there were a few babies below the age of one year.

TABLE I

Age of the patient			Incidence during 1931-36
Up to 10 years	40
11 to 15	21
16 to 20	38
21 to 30	160
31 to 40	106
41 to 50	66
Over 50	24
TOTAL			455

Sex and caste of the patients were recorded and are summarized in table II. It will be seen that neither caste nor sex appears to have any significance so far as susceptibility to infection is concerned.

TABLE II

Rat-bite fever—caste and sex

Caste	Male	Female	Total
Hindus ..	236	115	351
Mohammedans	60	34	94
Anglo-Indians	2	2	4
Indian Christians	1	3	4
Other castes ..	2	..	2
	301	154	455

Location of the wound in these cases was mostly on the hand, arm, leg or foot; in a few cases the bite was inflicted on the face, eyebrow, nose, head, shoulder or abdomen. Bites on exposed parts were more apt to result in infection and production of the disease than on protected parts, where the clothing might wipe off the organism from the teeth. The bite of an infected animal may not invariably result in infection, since there were several instances of two persons being apparently bitten by the same rat and only one contracting the disease.

Treatment

In the treatment of this series we used four organic arsenical compounds, these being novarsenobillon (N.A.B.), solu-salvarsan, sulpharsenol and sulpharsamine. Before starting treatment

due precautions were taken to see that no definite contra-indications existed against the use of arsenical compounds in any of the patients.

During the period 1934-36, 128 patients suffering from rat-bite fever were treated with novarsenobillon, three intravenous injections being given at intervals of 5 to 7 days. The ages of these patients varied from 16 to 66 years and the usual dosage administered was 0.3 gm. for the first injection, 0.45 gm. for the second and 0.45 to 0.6 gm. for the third injection. Some patients who were given smaller doses (0.15, 0.3 and 0.45 gm.) also responded to treatment. All the cases reacted to treatment in this group and there were no failures.

Intramuscular injections of solu-salvarsan were tried on 174 cases during the period 1934-36. The age of the patients varied from 4 months to 60 years. The usual curative dosage for adults was three weekly intramuscular injections of 3, 4 and 5 c.cm. of the drug. In this series 9 patients relapsed and were successfully treated afterwards with the usual doses of N.A.B. This compound is in solution and is often stored by druggists in this country for varying periods under conditions of high temperature and humidity before it is used. There is, therefore, considerable risk of its deterioration.

During 1934-36 sulpharsenol was used in the treatment of 20 cases (9 children and 11 adults). Generally three intramuscular injections at weekly intervals were given. All the nine children were cured and no relapses were reported. The dosage for children was: 0.25, 0.25 and 1.0 cg. for babies 2 to 3 months old; 1.0, 1.0 and 1.0 cg. for those 4 months old and 6.0, 12.0 and 18.0 cg. for those 9 years old. Out of a series of 11 adults, 6 came back with relapses and were subsequently cured with the usual dosage of N.A.B. Five adults, however, recovered, the curative dose in these being 24.0, 30.0 and 36.0 eg. in three injections. For children it is advisable to use this drug, as it is less toxic and more convenient, inasmuch as it can be given by the intramuscular route and does not produce any pain. In adults there were failures with the dosage prescribed above, but it is possible that higher doses might be more effective.

Lastly, at the suggestion of Dr. J. C. Gupta, sulpharsamine (Thiarsin), a new arsenical compound manufactured by Messrs. Bengal Chemical and Pharmaceutical Works, was tried in a series of 17 cases of rat-bite fever. The ages of the patients varied between 17 and 56 years. The usual curative adult dose was found to be three intravenous injections of 0.3, 0.45 and 0.6 gm. of the drug respectively, at intervals of 5 to 7 days. No untoward symptoms were observed and no relapses occurred in the cases treated. This compound is worthy of further trial as it is prepared in India and is cheaper.

Sulpharsamine (Thiarsin) can be administered by the intramuscular route also and has been

largely used in this way in the treatment of syphilis, without any untoward symptoms.

The results of administration of the various arsenical compounds are given in the following table :—

TABLE III.

Drug	Number of cases	Number cured	Number relapsed
N.A.B. ..	128	128	None
Solu-salvarsan ..	174	165	9
Sulpharsenol ..	20	14	6
Sulpharsamine ..	17	17	None

We have observed that in some patients treated with sulpharsenol in usual doses, not only was the cure not affected but the subjects became resistant and needed larger dosage and a more prolonged course of N.A.B. to effect a cure. It is difficult to explain this condition as Robertson (1930) stated that small doses of arsenical compounds do not cause the formation of arsenic-resistant forms.

Summary

In Calcutta, rat-bite fever appears to be mainly a hot weather disease.

During the period 1931 to 1936, 876 cases attended the out-patient department of the School of Tropical Medicine with history of rat-bite; 455 of these developed typical symptoms of rat-bite fever. Out of 191 examined *S. minus* was isolated from 123 cases from the exudates from the site of bite. Out of 69 cases examined by animal inoculation 49 gave positive results. The rest were clinically typical cases of rat-bite fever and all responded to arsenical treatment. N.A.B., sulpharsenol, solu-salvarsan and sulpharsamine were used for treatment. Of 128 cases treated with N.A.B. all were cured. Some cases which relapsed with sulpharsenol and solu-salvarsan were cured with N.A.B. Out of 20 cases treated with sulpharsenol 6 relapsed, the rest were cured. Out of 174 cases treated with solu-salvarsan 9 relapsed and the rest were cured. Seventeen cases treated with sulpharsamine were all cured.

Two drug-resistant cases are recorded.

TREATMENT OF LOBAR PNEUMONIA WITH M. & B. 693

By ANTHONY CAPLAN, M.D., M.R.C.P. (Lond.)
 Senior Assistant Medical Officer, Kolar Gold Fields Hospital

THE introduction of antipneumococcal serum in the treatment of pneumococcal infections constituted the first real advance in pneumonia therapy in recent years. It was the only treatment to give consistently good results. The great expense, the special facilities needed for typing, and the fact that treatment is most efficacious when instituted before the third day of the disease, made its general use impossible. More recently, hopes were raised when sulphanilamide was added to the physician's armamentarium, but in pneumococcal infections the results were at first disappointing. In 1938 Whitby demonstrated that M. & B. 693, a drug related to sulphanilic acid and to aminopyridine, protected mice against 10,000 lethal doses of pneumococci type I. Later in the year Evans and Gaisford (1938) published the results of the treatment of 100 cases of lobar pneumonia with M. & B. 693. The mortality was 8 per cent compared with 27 per cent in a controlled series of 100 untreated cases. It was also obvious that in the treated cases the temperature fell to normal sooner than in the controlled series. Further encouraging reports on the use of this drug in lobar pneumonia have since appeared [Dyke and Reid (1938), Anderson (1939), Agranat *et al.* (1939)].

Lobar pneumonia on the Kolar Gold Fields

The Kolar Gold Fields Medical Department supervises the health of 28,000 mining employees, 60 per cent of whom are underground workers. The average number of patients admitted annually to the hospital totals 5,000. Table I gives the number of admissions for the years 1934 to 1938 of patients suffering from lobar pneumonia and the mortality rates. It also demonstrates that this disease accounts for more deaths than all other diseases.

TABLE I

Year	Cases of lobar pneumonia treated	Number of deaths	Death rate per 100 treated	Per cent of pneumonia deaths to total mortality
1934	353	136	38.5	60.1
1935	245	138	56.3	59.4
1936	238	94	39.5	54.9
1937	273	62	22.7	48.0
1938	254	69	27.1	47.1

It is evident from these figures that lobar pneumonia on the Kolar Gold Fields is a disease of major importance. The exceptionally high mortality rate for 1934 to 1936 could be attributed to the increased virulence of the invading organism. One other factor which has certainly helped to swell the death rate is the difficulty experienced in inducing coolies to report sick at the onset of their illness. In recent years, however, as the result of a campaign encouraging coolies to report sick on the first signs of illness, there has been an appreciable improvement in this respect. Table III tends to confirm this fact; of the present series of cases (treated in 1938-1939), 43 per cent were admitted to hospital after the third day of their disease, compared with 61 per cent in a series of cases treated in 1937-1938. The lower mortality rates for the years 1937 and 1938 might in part be due to the earlier admission of patients to hospital, combined with the improved conditions under which the coolie is housed, and the improved nursing facilities.

The resistance of the coolie to infection is low, and malnutrition is common. In the present series of 100 cases, 12 had signs of a vitamin-B deficiency. The tongue and mouth lesions in all cases responded to marmite therapy. Hookworm infestation is common. In 1938, Dr. W. B. Roantree found evidence of hookworm in 77 per cent of coolies examined. It is unlikely, however, that excepting in severe infestations is the course of the disease affected. The underground worker is also liable to respiratory disease associated with the inhalation of dust. Evidence of the severity of lobar pneumonia on the Kolar Gold Fields is the comparatively large number of cases with consolidation of more than one lobe—37 per cent in the present series, as compared with 9 per cent in the 100 cases reported by Evans and Gaisford.

The paper of Evans and Gaisford was so impressive that it was decided to treat all cases of lobar pneumonia with M. & B. 693. It was realized that the omission of a series of controls would detract from the scientific value of the work, but it was felt there was no justification in withholding the drug. One hundred cases (96 coolies and 4 Anglo-Indians) have been treated with M. & B. 693 from November 1938 to March 1939. Thirty-six were classified on admission as mild, 34 moderate, and 30 severe. One hundred and sixty-four cases treated by the writer between March 1937 and October 1938 are cited as a comparison. It is a notorious fact that the virulence of pneumococcal infections varies from year to year, and that the results of the treatment of series of cases at different times are not strictly comparable. Nevertheless, if only because of the striking differences, a comparison is made. Apart from the use of M. & B. 693 in the present series, the treatment in all cases was identical and was purely symptomatic.

Chemical structure of M. & B. 693 and dosage

M. & B. 693 is related to sulphanilic acid and to aminopyridine, and has the following formula:—

It is supplied for oral administration in tablets containing 0.5 gramme of the active substance, and for parenteral administration in ampoules each containing a similar quantity of the drug. The tablets are easily swallowed with water and have a faintly bitter taste. The parenteral route was not employed in this series.

The first sixteen cases received 2 tablets (1 gm.) *t.d.s.*, but this dose was found to be inadequate for the more severe cases. All patients admitted after the beginning of December 1938 were given 3 tablets (1.5 gm.) four-hourly for the first twenty-four hours then 2 thrice daily continued until the patient was afebrile for twenty-four hours. Occasionally in cases not responding after two days, the dose was increased to 3 tablets four-hourly or *t.d.s.* The majority of cases therefore received 15 or 18 tablets (7.5 or 9 gm.) in the first twenty-four hours, and subsequently 6 tablets (3 gm.) daily. The smallest dose given to an adult was 6 gm. and the largest 82 gm. (case 76). Seventy-three per cent of all cases received 15 gm. or less.

Action of M. & B. 693

Fleming (1938) has shown that M. & B. 693 'retards the growth in human blood of pneumococci and streptococci in concentrations which is reasonable to suppose can be obtained therapeutically'. The action of the drug is bacteriostatic and not bacteriocidal. Presumably rapid development of pneumococci in the blood is in some manner prevented, and the polymorphonuclears are able to overcome the bacterial invasion sooner than if the drug was withheld. Flippin *et al.* (1939) estimated the concentration of M. & B. 693 in the blood of pneumonia patients treated with the drug. They found concentrations varying from 1 to 18 mgm. per 100 c.cm., and the therapeutic action appeared to be as good in patients with a low concentration as in those with a high concentration. The findings of these workers are conflicting with clinical experience, and further research is necessary before the action of the drug is clearly understood.

Age incidence

Table II gives the age incidence of 100 cases treated with M. & B. 693, and 164 untreated cases; about 70 per cent of cases in both groups were aged between 20 and 40.

TABLE II
Age incidence

Age	Under 20	20-29	30-39	40-49	Over 49
Number of cases treated with M. & B. 693.	2	44	32	16	6
Number of cases not treated with M. & B. 693.	7	75	45	27	10

Type

Typing of the pneumococci was attempted in all cases in which sputum was expectorated. Unfortunately the only types of antipneumococcal sera available were I and II; the findings in this respect are therefore incomplete. The direct typing method was used in all cases; of 85 sputa examined, type I pneumococcus was found in 18, type II in 6, and 61 were unclassified.

Day of disease on admission

Table III gives the day of disease on admission of the treated and untreated cases. Fifty-six per cent of the treated cases and 39 per cent of the untreated cases were admitted on the second or third day of the illness.

TABLE III
Day of disease on admission

Day	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th
Number of cases treated with M. & B. 693.	1	17	39	18	11	5	2	3	2	2
Number of cases not treated with M. & B. 693.	0	19	45	56	18	12	7	2	3	2

The response to treatment

The response to treatment was classified as 'dramatic' (7 per cent), when a crisis took place within twenty-four hours in severely ill patients; 'excellent' (61 per cent) in all cases resolving within forty-eight hours; 'good' (13 per cent) either when a response was apparent after forty-eight hours, or when a sustained pyrexia (without toxæmia) recurred after an early primary fall in temperature; 'indefinite' (3 per cent); and 'none' (16 per cent). The last two terms are self-explanatory.

Table IV shows the day of treatment on which the temperature fell to normal.

Seventy per cent of cases ended in a 'crisis' during the first and second days of treatment. Most patients were admitted at midday and the

treatment was not instituted until the early afternoon. The fall in temperature in these

TABLE IV

Day of treatment on which the temperature fell to normal

Day	1st	2nd	3rd	4th	5th	6th	7th	Drug stopped	Deaths
Number of cases	9	61	9	2	4	2	3	5	5

cases, therefore, took place within thirty-six hours of the beginning of treatment. Coincident with the fall of temperature, there was usually a fall in the pulse and respiration rates and a pronounced improvement in the general condition. The 'crisis' appeared to be as dramatic as the normal crisis in lobar pneumonia. In some 20 per cent of these cases there was a 12 to 18 hours' lag in the fall of the pulse and respirations, and a delay in the disappearance of the toxæmia.

In 16 per cent of all cases a secondary pyrexia lasting 1 to 7 days occurred. No sign of spread of disease was found and toxæmia was absent (figure 2). This phenomenon has also been described by Evans and Gaisford (*loc. cit.*) and by Anderson (*loc. cit.*); it was found to have no clinical significance. Occasionally a relapse occurred 6 to 12 hours after an apparent response (figure 3), seeming as though the scales were weighed just in favour of the invading

Fig. 1 (case 63).—Excellent response on 2nd day of M. & B. 693 (4th day of disease). Total M. & B. 693 given was 12.5 gm.

Fig. 2 (case 82).—Excellent response on 2nd day of M. & B. 693 (4th day of disease). Total M. & B. 693 given was 16 gm.

organism. Continuation of M. & B. 693 in increased doses sometimes resulted in a permanent fall in temperature, pulse and respiration rates, but more often there was no noticeable effect. The disease spread in 9 cases including 3 which ended fatally. The 3 cases classified as 'indefinite' were all severely ill; in 2 the temperature fell to normal in five days, and in 1, four days after the commencement of treatment. The 16 cases which did not respond included the 5 deaths. Figures 1, 2, 3 and 4 are specimen temperature charts.

Mortality rate

The mortality rate was 5 per cent. The following 5 cases ended fatally :—

Case 14.—Hospital compounder, *æt.* 49. Chronic alcoholic. Diabetic. Hyperpietic (blood pressure 190/100). Whilst on leave, developed a febrile illness with cough. Treated himself with quinine for malaria. Travelled 200 miles, and arrived at the Kolar Gold Fields Hospital on the 8th day of his illness. He was gravely ill, temperature 102, pulse 130, and respiration 50. Consolidation of left upper and lower lobes and right lower lobe. Sputum rusty, type indefinite. White blood count 15,000, polymorphs 76 per cent, large mononuclears 6 per cent, lymphocytes 18 per cent, eosinophiles 0 per cent. He was given M. & B. 693 3 tablets *t.d.s.* for 4 days (22.5 gm.), and insulin 20 units *b.d.* There was no improvement, persistent hiccups developed and the drug was stopped. The pyrexia persisted, and on the 8th day of admission (15th day of disease), M. & B. 693 was again exhibited, 3 tablets

Fig. 3 (case 67).—Apparent response in 24 hours followed by a relapse. Crisis on 4th day of M. & B. 693 (6th day of disease). Response classified as 'indefinite'. Total M. & B. 693 given was 24 gm.

Fig. 4 (case 85).—Apparent response in 36 hours. Relapse. Death. Total M. & B. 693 given was 18.5 gm.

q.q.h. for 24 hours then 3 *t.d.s.* for 7 days. White blood count 16,000, polymorphs 77 per cent, large mononuclears 3 per cent, lymphocytes 20 per cent, and eosinophiles 0 per cent. On the 11th day of admission there were signs of spread to right upper lobe, and the following day 10 c.cm. of slightly opalescent fluid was aspirated from the right base. The fluid contained pus cells and yielded a pure culture of *S. pneumoniae*. The drug was stopped on the 11th day; total given was 49.5 gm. The patient steadily went down hill and died on the 31st day of disease (24th day of admission).

Case 37.—Underground coolie, *æt.* 45. Admitted on 8th day of disease. General condition extremely poor. Temperature 102, pulse 140, and respiration 60. Consolidation of left lower lobe. Sputum rusty, type I pneumococcus. M. & B. 693 3 tablets *q.q.h.* for twenty-four hours was given, then 2 *t.d.s.* until death ensued. There was an early temporary improvement, but on the 4th day of admission (11th day of disease) there were signs of spread of disease to the right lower lobe. The general condition deteriorated and the patient died seven days after admission to hospital (14th day of disease). Total M. & B. 693 given over a period of seven days was 22 gm.

Case 43.—Underground coolie, *æt.* 30. The patient was too ill on admission to give a lucid history, illness began 7.5 days previously. Temperature 101, pulse 140, and respiration 60. Consolidation left upper lobe and generalized rhonchi throughout both lungs. Sputum not expectorated. M. & B. 693 3 tablets *q.q.h.* was given for twenty-four hours, then 2 *t.d.s.* for thirty-six hours. Total 13.5 gm. Death took place 60 hours after admission.

Case 62.—Underground coolie, *æt.* 23. Admitted on 3rd day of disease. General condition fair. Temperature 103, pulse 110, and respiration 40. Consolidation

left lower lobe. Sputum rusty, type I. M. & B. 693 3 tablets *q.q.h.* given for twenty-four hours then 2 *t.d.s.* for two days. Condition worse on 4th day of admission (6th day of disease), and signs of spread of disease to left upper lobe. White blood count 12,000, polymorphonuclears 72 per cent, large mononuclears 3 per cent, lymphocytes 26 per cent, eosinophiles 0 per cent. Dose M. & B. 693 increased to 3 *q.q.h.* for twenty-four hours, then 2 *t.d.s.* until the patient died on the 7th day of admission (9th day of disease). Total M. & B. 693 given over a period of seven days was 28.5 gm.

Case 85.—Underground coolie, *æt.* 22. Admitted on 3rd day of disease. First seen by me on 5th day of disease. General condition poor. Temperature 105, pulse 130, and respiration 50. Consolidation left upper and lower lobes and right lower lobe. Sputum rusty, type indefinite. M. & B. 693 3 tablets *q.q.h.* given for twenty-four hours, then 3 *t.d.s.* for twenty-four hours and 2 *t.d.s.* for two days. Total 18.5 gm. in four days. There was a fall of temperature within 48 hours from 105 to 99.6, but no corresponding fall in pulse rate. The following day the temperature rose to 102.4, the patient became delirious and died on the 4th day of treatment (8th day of disease) (figure 4).

A fatal termination was expected in cases 14, 37 and 43. Case 14 was a chronic alcoholic and diabetic, and was admitted on the 8th day of his illness, there was in addition the complication of a staphylococcal pleural effusion. He was one of the first sixteen cases to be treated, and the initial dose may have been too small. Case 37 was admitted on the 8th day of the disease and was severely ill. Case 43 was moribund on admission and was expected to die within a few hours. The lack of response in cases 62 and 85 was disappointing. Case 62 was admitted on the third day of the disease and his general condition gave no cause for anxiety. The dose of the drug was adequate, and there was no vomiting. Case 85 gave an early response which unfortunately was not maintained.

It is interesting to note that of the 5 cases, type I pneumococcus was found in the sputum in 2 cases. The type was unclassified in 2 cases and sputum was not expectorated in 1 case.

Post-mortem examination was refused in all cases.

Toxic symptoms

The absence of severe toxic symptoms was impressive, even when large doses of the drug were administered. Case 76 received 82 gm. over a period of 27 days without any untoward effects. Nausea and vomiting were the only common symptoms and occurred in 17 cases, but were never severe enough to indicate withdrawal of the drug. When vomiting occurred the dose was repeated, and in almost all cases the drug was retained. One case complained of abdominal pain, and in 4 cases (all severely ill) a confused mental state, persisting for 1 to 2 days after the crisis, was observed. Repeated differential white blood counts were done in 10 cases, and no tendency to granulocytopenia was apparent. Spectroscopic examination of the blood for methæmoglobinæmia and sulphæmoglobinæmia was not attempted. Severe cyanosis was not seen, but it is realized that mild degrees in a dark-skinned person can easily be missed.

(An interesting symptom observed in a patient treated for gonorrhoea was the appearance of dysarthria after the patient had taken 12 gm. of M. & B. 693 in 3 days. The drug was stopped and the speech became normal in 48 hours.)

Complications

Case 14 developed a staphylococcal pleural effusion; the patient ultimately died. This was the only complication in the series. In the control series of 164 cases, the following complications occurred: 3 unresolved pneumonias, 1 sterile effusion, 1 lung abscess, and 1 pneumococcal peritonitis.

Comparison of results

The mortality rate of 5 per cent in the 100 treated cases compares favourably with 18.8 per cent in the 164 cases treated without M. & B. 693. Reference to table V, which gives the day of disease on which the temperature became normal, shows as striking a difference. In the treated cases, 76 per cent became afebrile before the 8th day of the disease, compared with 10.5 per cent in the untreated cases. The contrast is graphically represented in figure 5.

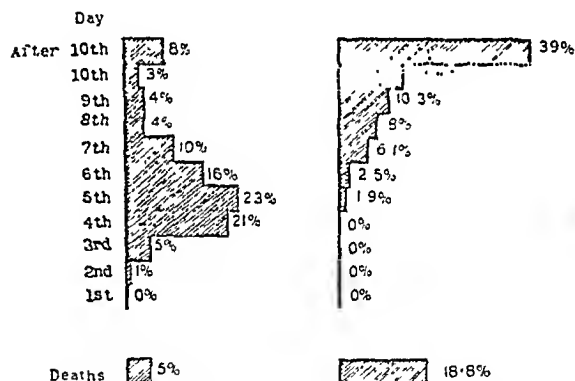

Fig. 5.—Day of disease on which the temperature fell to normal. (Graphic representation.)

Cases treated with M. & B. 693. Cases not treated with M. & B. 693.

TABLE V

Day of disease on which temperature became normal

Day	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th	After 10th
Number of cases treated with M. & B. 693	0	1	5	21	23	16	10	4	4	3	8
Number of cases not treated with M. & B. 693	0	0	0	0	3	4	10	13	17	22	64

Complications were less common in the treated cases, 1 per cent compared with 3.6 per cent. The routine procedure before the introduction of M. & B. 693 was complete rest in bed for 14

days after the patient became afebrile, discharge from hospital 5 to 6 days later, then 1 month's sick leave before resumption of duty. The uncomplicated cases were therefore off duty for 7 to 8 weeks. The relatively mild course, and more rapid convalescence of patients treated with M. & B. 693, enabled this period to be shortened appreciably. The duration of stay in hospital for the average case treated with M. & B. 693 was reduced to 12 to 18 days, the sick leave to 2 weeks, and the period of off duty to about 4 weeks (a saving of at least 3 weeks).

Conclusions

It is too soon to dogmatize as to the value of M. & B. 693 in the treatment of lobar pneumonia. Comparatively few cases have been treated, and the drug must still be considered to be under trial. The experience gathered in this series, in addition to reports published up to date, encourages the prediction of an optimistic future for the treatment of lobar pneumonia. The response to M. & B. 693 in the majority of cases is most impressive. The mortality rate in all published reports is well below 10 per cent. A crisis usually occurs many hours or even days earlier than would normally be expected. A fall of temperature to normal within 48 hours of the beginning of treatment is seen in about 80 per cent of cases. Clinical experience indicates that an adequate initial dosage is essential and that if no signs of response appear by the third day of treatment, it is questionable whether the drug should be continued.

A small proportion of cases do not respond (16 per cent in the present series), the reason for the absence of response will only be known when the action of the drug is fully understood. It is worth noting that of the 16 failures, 6 were type I (37.5 per cent). Maclean *et al.* (1939) in an important recent paper showed that there are great differences in the sensitivity of the pneumococcus to M. & B. 693, independent of the type. These workers also produced experimental evidence in mice, of the synergic action of pneumococcal vaccine and M. & B. 693. In some of the failures in the present series, it was felt that an adjuvant to M. & B. 693 might well have tilted the scales in favour of the patient. Barach (1931) has shown that large doses of pneumococcal vaccine can be administered to patients suffering from lobar pneumonia, without any risk, and that the presence of immune bodies in the blood can be demonstrated after 3 to 4 days. A combination of polyvalent pneumococcal vaccine and M. & B. 693 may be worthy of a trial in selected cases.

Summary

1. The results of the treatment of 100 cases of lobar pneumonia with M. & B. 693, admitted to the Kolar Gold Fields Hospital between November 1938 and March 1939, are discussed.

TREATMENT OF NERVOUS DISEASES BY VITAMIN B₁ WITH SPECIAL REFERENCE TO TRIGEMINAL NEURALGIA

(A REPORT OF 7 CASES)

By I. BAKHSH, M.D. (Lond.), M.R.C.P. (Lond.)
MAJOR, I.M.S.

Professor of Pharmacology and Therapeutics, K. J. Medical College, and Physician to Out-Patients Department, Mayo Hospital, Lahore

VITAMIN-B therapy of nervous diseases dates back to 1897, when Eijkman discovered that the feeding of chicks with polished rice produced symptoms resembling beri-beri in man. Beri-beri was from now onward treated successfully with crude preparations of vitamin B from rice husks, etc. In 1927, Jansen and Donath isolated from rice husks vitamin B₁ in a pure and crystalline form which could be used parenterally with consequent increase in its therapeutic efficiency.

During the last decade a good deal of work has been done on the absorption, fate and utilization of this important vitamin and its therapeutic claims have been extended to other forms of polyneuritis. It has been suggested that the various forms of polyneuritis are due to vitamin-B₁ deficiency and differ from beri-beri only in the particular mechanism by which the deficiency is brought about and include alcoholic polyneuritis, polyneuritis of pregnancy, post-infective polyneuritis, polyneuritis as a result of gastro-intestinal disease, and even diabetic, arsenic and lead polyneuritis.

Recently, great emphasis has been laid on the various ways in which vitamin-B₁ deficiency is

(Continued from previous page)

2. The mortality rate was 5 per cent.

3. The temperature fell to normal within thirty-six hours of the beginning of treatment in 70 per cent of cases.

4. Seventy-six per cent became apyrexial before the eighth day of the disease.

I wish to acknowledge my thanks to the managers of the Kolar Gold Fields, Messrs. John Taylor and Sons, 6, Queen Street Place, London, E.C.4, for their permission to publish this paper, and to the Chief Medical Officer, Dr. W. B. Roantree, for his valuable criticisms.

caused, and rightly so, for success in therapeutics depends largely on the exact knowledge of the causative factor. Avitaminosis B₁ may be due to one or more of the following causes:—

(1) Insufficient intake due either to extreme poverty but more often to ignorance and food faddism, various forms of anorexias either functional or as a result of drug addiction and heavy smoking, persistent vomiting of pregnancy, and pyloric stenosis. Beri-beri has recently been described in anorexia nervosa.

(2) Defective absorption due to functional or organic lesions of the digestive tract, especially alcoholic gastro-enteritis, sprue, persistent ill and other diarrhoeas, chronic dysenteries, intestinal tuberculosis, gastro-colic fistula and pellagra.

(3) Increased requirements. Cowgill (1938) has shown that vitamin requirements of man are directly proportional to body-weight, caloric intake, and metabolism. Beri-beri is more common in those countries where the staple diet consists mainly of polished rice which has high caloric but low vitamin value, infections, excessive physical exertion, thyrotoxicosis and pregnancy, by raising the body metabolism, often help to precipitate the acute symptoms of B₁ deficiency.

It is very rare that a single factor is the cause of vitamin-B₁ deficiency. For example, alcoholic polyneuritis results not only from insufficient intake and defective absorption due to gastro-enteritis but is due also to the high caloric value of alcohol. Similarly in pregnancy there is greater demand due to increased metabolism and extra requirements by the foetus and at the same time there is inadequate intake as a result of vomiting.

Vitamin B₁ being water soluble is not stored in the body hence symptoms of deprivation appear much earlier than in the case of fat soluble vitamins A, D and E. Again deficiency of vitamin B₁ is very rarely single; the factors which cause B₁ deficiency may also produce lack of other vitamins as well as iron, calcium and phosphorus. For instance, in chronic lead poisoning in addition to the nervous signs there is not infrequently parodontosis and finally loss of teeth due to a vitamin-A deficiency and the severe calf pains due to hæmorrhages as a result of vitamin-C deficiency. It is not very unusual to find beri-beri associated with pellagra in chronic alcoholics. These points are of great practical importance in successful therapy of not only vitamin B₁ but also of other vitamin deficiencies.

Vitamin-B therapy.—Vitamin B₁ has been used in a variety of nervous disorders with brilliant results in some cases but equally disappointing ones in others. It is too early to remark about the future of vitamin B₁ in the various diseases of the nervous system and the clinical data at present available is too scanty to indicate B₁ therapy in all such diseases. The variability of success is due to many causes.

Firstly, we possess no reliable test for estimating B₁ deficiency and secondly there is no consensus of opinion about adequate dosage. Again the changes produced by deficiency of vitamins which are only biochemical and functional in the beginning become structural later and any structural change in the case of nervous tissue is extremely difficult to repair.

In addition to the various forms of polyneuritis, vitamin B₁ has been advocated for the treatment of neuralgias and affections of the brain and spinal cord, such as subacute combined degeneration, disseminated sclerosis, tabes dorsalis, and amyotrophic lateral sclerosis. Encouraging results have been obtained by some with large doses of vitamin B₁ in these cases and recently Metildi (1939) has reported complete or partial relief in six cases suffering from tabetic pains which were unaffected by antisiphilitic treatment.

I have used vitamin B₁ in doses of 10 mg. daily in a case of early disseminated sclerosis for over one month without the slightest improvement. In another case of diabetic polyneuritis, oral and parenteral administration of 10 to 20 mg. of B₁ without insulin for one month produced no effect on the sensory changes, in fact the patient complained of exaggeration of tingling and burning sensations in the hands and feet. When his urine became sugar-free after insulin therapy he was relieved within a few days. Two cases of arsenical neuritis were uninfluenced by prolonged vitamin-B₁ therapy, although similar dosage in four cases of polyneuritis of unknown origin produced satisfactory results and the improvement was noticeable in the first week of treatment. One case of nerve deafness did not respond to six weeks of B₁ treatment given by mouth as well by injection.

In 1936, Böhm treated two cases of trigeminal neuralgia with injections of crystalline vitamin B₁ (Betaxin) with complete success. In the case of a female 41 years old, dental treatment and alcohol injections had already been tried without any effect. She was given one injection of 'Betaxin' daily. Improvement was noticeable after the fourth injection and was complete after the seventh injection. The second case required 14 injections.

In the same year Hofer von Lobenstein (1936) tried vitamin B₁ in one case each of neuralgia, of the trigeminal, occipital and intercostal nerves, and in two cases of sciatica. He gave 6 to 10 intramuscular injections with satisfactory results in all.

Molnar (1937) also described a case of trigeminal neuralgia in a female 51 years of age, in whom all previous treatment was without any effect. She received daily injections of vitamin B₁ for 16 days and left hospital without symptoms. After some time pain returned but was not so bad.

Last year I requested Lieut.-Colonel V. R. Mirajkar, Professor of Surgery, K. E. Medical

College, Lahore, to let me treat a case of trigeminal neuralgia which had come to him for alcohol injection. Vitamin-B₁ therapy in this case was so successful that Colonel Mirajkar afterwards referred all his cases of trigeminal neuralgia to me. So far seven cases have been treated and with the exception of one all have been greatly benefited by this treatment. None of the six cases have so far relapsed. In none of these cases was any other treatment, such as removal of carious teeth, given.

Case 1, male, aged 66, complained of paroxysms of severe pain on the left side of the face on talking, eating and drinking. Duration 2½ years. Moderate addiction to opium for the last 20 years. Physical examination showed a well-nourished individual with majority of teeth carious, some having already been removed. Removal of teeth had no effect on the neuralgia. All three branches of the nerve affected. Treated with intramuscular injections of 30 mgm. of B₁ daily for the first two days and then 10 mgm. daily for another ten days. Slight but definite improvement was noticed after the first 48 hours of treatment and after one week the patient was completely free from pain. Total dosage 160 mgm.

Case 2, male, 44 years. Complained of paroxysms of severe pain on the right side of the face; duration 11 months: general nutrition good. Teeth although sound had been removed on the advice of the patient's physician. All the three branches of 5th nerve involved. Given 30 mgm. of B₁ daily by intramuscular injections for one week. Improvement commenced within 48 hours and was complete after five days. Total dosage = 210 mgm.

Case 3, male 65 years. History of 12 years of neuralgic pain on the left side of the face. For the first five years the pain was moderate in intensity but later became more acute. General nutrition fair. All the teeth on the left side had been extracted, those of the right side were apparently normal. All the three branches of the 5th nerve involved. Given 6 mgm. of B₁ intramuscularly daily. After two weeks' treatment was relieved by 50 per cent but had to give up treatment on account of urgent family affairs. Total dosage = 84 mgm.

Case 4, male, 60 years. Three months earlier had a gumboil on the right side which was incised, but the pain had persisted. Lately it had become intolerable and came on when eating, drinking and even speaking. General nutrition good. All teeth on the affected side had been removed. All the branches of 5th nerve involved. Given intramuscularly B₁ in 6 mgm. doses daily for two weeks. Improvement commenced within the first week and was complete after the tenth injection. Total dosage = 84 mgm.

Case 5, male, 60 years. Four years' history of neuralgic pains on the right side of the face and scalp, attacks came on while eating, drinking and talking. The pain usually started first in the scalp and then spread downwards till it involved the whole of the right side of the face. General nutrition good. All the teeth on the right side except one premolar and two canines in the lower jaw had been extracted, most of the teeth on the left side were carious. Right side showed slight wasting but sensations were intact. Given 10 mgm. of B₁ daily by intramuscular injections. On the fourth day of treatment felt a good deal of relief in the severity and frequency of paroxysms but next day had recurrence of pain and could not sleep at night. After the 7th injection he started improving again. After the 10th injection he was benefited by 30 per cent but two further injections had no more effect and the treatment was abandoned. Total dosage = 120 mgm.

Case 6.—M. D., aged 65 years. He suffered from severe neuralgic pains on the right side of the face for the last six years. He had eight injections of alcohol, each injection giving him relief for three months

and the last one for one year. Now the attacks were more frequent and the pain was worse.

Treated with 10 mgm. of B_1 given intramuscularly every day. There was complete relief after the sixth injection but the pain recurred by 25 per cent after the ninth injection. Vitamin treatment was stopped and he was given potassium bromide gr. 5 and luminal gr. $\frac{1}{2}$ twice daily instead. After one week he again got complete relief and has remained well since. Total dosage = 90 mgm.

Case 7.—N. A., aged 25 years. Six years' history of neuralgic pain confined to the distribution of the right 5th nerve. Stated that he had suffered from gonorrhœa and syphilis seven years before but the Wassermann reaction was negative. Examination showed fair nutrition, all the three branches of the 5th nerve were involved and there was watering of the right eye and right side of the nose. There was very slight wasting of the right side of the face but the sensations were intact. Was given an alcohol injection one year before which gave him complete relief for nearly eleven months. Teeth normal. Given B_1 by intramuscular injections in doses of 10 mgm. daily for seven days but there was no relief. Total dosage = 70 mgm.

Discussion

The above account of seven cases of trigeminal neuralgia shows that only one case did not respond to vitamin- B_1 therapy. This patient gave a history of syphilis and although the Wassermann reaction was negative he was given a course of mercury and iodides by mouth without any relief. Of the six cases which responded to treatment four got 100 per cent relief, one about 50 per cent and one about 30 per cent. Case 3, who obtained about 50 per cent relief, received 84 mgm. of B_1 and case 5 who improved by about 30 per cent received 120 mgm. The four cases which were completely relieved received 160, 210, 84 and 90 mgm. each and in all of them improvement commenced promptly and in two cases was complete when only 50 mgm. of the vitamin had been given, although treatment was continued for a few days more. It is difficult to say whether prolonged treatment with perhaps bigger doses would have benefited cases 3 and 5 any more.

It is generally believed that vitamin B_1 even when given in enormous doses does not cause any toxic symptoms and Weiss and Wilkins (1937) have given 100 mgm. of crystalline B_1 intravenously without any ill effects. However, recently Steinberg (1938) has reported untoward effects from using large doses of vitamin B_1 . In three of his patients herpes zoster occurred after large doses and in one case he was able to produce herpes on two successive occasions. Steinberg believes that vitamin B_1 when given in large doses is capable of irritating the peripheral nerve plates. In the case of diabetic polyneuritis above referred to there was definite worsening of burning and tingling sensations in the hands and feet after continued use of moderate doses of vitamin B_1 . In case 6 the recurrence of neuralgic pains might be due to the irritant action of B_1 on the sensory nerve endings as the patient was relieved when the

B. SEN, B.Sc., M.B.

and

Z. AHMED, M.B., D.P.H.

(From the School of Tropical Medicine, Calcutta)

Giardia lamblia is a common parasitic intestinal flagellate. With regard to its geographical distribution, this is now known to be world-wide.

(Continued from previous column)

injections were stopped and bromides and luminal were given instead.

Conclusions

Vitamin B_1 is proving to be of great therapeutic value in many diseases of the nervous system for which there was no satisfactory remedy before. The clinical data are too scanty to evaluate its efficacy in all the diseases for which it is advocated but it seems to be of particular value in many forms of polyneuritis. Whether the action of vitamin B_1 is due to its replacing any deficiency or to some other action is not quite clear yet.

In a short series of seven cases of trigeminal neuralgia injections of B_1 have given complete relief in four and partial relief in the other two, while one was unaffected. The relief obtained was dramatic in all the four cases and considering that trigeminal neuralgia is a difficult disease to treat without operation, which in itself is a definite surgical risk, vitamin B_1 promises to be of considerable therapeutic value and should be given a trial in all cases of trigeminal neuralgia.

My thanks are due to Lieut.-Colonel V. R. Mirajkar, O.B.E., I.M.S., for permission to treat his cases and to my assistant demonstrator Dr. Abdul Qayyum Malik, M.B., B.S., for his great help. I am also indebted to Messrs. Merck & Co. and Hoffmann-La Roche & Co. for supplying me with their products 'Betabion' and 'Benerva' respectively.

The incidence in the tropics is certainly higher than in the temperate zones. The following table gives the incidence of infection with *Giardia lamblia* among the patients treated for various diseases at the Carmichael Hospital for Tropical Diseases and in the out-patient department of the School of Tropical Medicine, for four years.

Giardia lamblia inhabits the lumen of the small intestine, the duodenum being the commonest site of infection. On this account the

TABLE

	Total number of stools examined	Number showing infection with <i>Giardia lamblia</i>	Incidence, per cent
1934 ..	4,302	246	5.8
1936 ..	5,498	380	6.8
1937 ..	4,766	226	4.7
1938 ..	4,710	357	7.6

motile forms are not usually seen in the stool; but when the patient has diarrhoea, the contents of the small intestine are passed down rapidly and it is then that the active phase of the parasite is encountered in the stool. Encystation takes place in the large bowel and in most cases diagnosis of the infection with *Giardia* is made by finding the cysts in the stool. Excretion of the cysts in the faeces is markedly intermittent so that care should be taken in drawing conclusions as to the effectiveness of any drug administered.

A host of drugs, e.g., treparsol, stovarsol, carbarsone, bistovol, bismuth subgallate, neosalvarsan, yatren, etc., have been used by various workers in cases of infection with *Giardia* but without any appreciable success. We have tried stovarsol, carbarsone and yatren in many cases, the majority of which did not respond to the treatments. In a few instances, however, the parasites disappeared after the treatment. But as the patients were not kept under observation for a reasonable period after the treatment had been discontinued, it is difficult to state with certainty that the infection was completely eradicated, for *Giardia*, as we have said before, reappears in the stool after absence for several days. Recently, Brumpt (1937) conducted experiments on lamblia-infected mice and has noted that, of all the treatments tested, oral administration of one per cent solution of quinacrine (a French equivalent of atebirin) for 5 days was able to bring about a cure in 80 per cent of the animals to which it was administered. Martin (1937) claims that atebirin in the doses employed for the treatment of malaria will rid the majority of patients of lamblasis of their flagellates. In a

few cases it may be necessary to repeat the course. In view of the striking results obtained with atebirin, as reported above, we have tried this drug on a number of cases using the same dose as for the treatment of malaria but have considered in this paper only those few cases which could be kept under observation for at least six weeks after the completion of treatment.

Case notes

Case 1.—Mrs. B. has been suffering from looseness of bowels and flatulence for the past two years. Stools examined in January last showed a heavy infection with *Giardia lamblia* (trophozoites and cysts) and *Trichomonas*. She was then treated with stovarsol and bismuth. There was a temporary amelioration of symptoms. No further examinations were possible at the time. On 2nd April, 1939, the symptoms recurred and the stools were full of *Giardia* cysts, *Trichomonas*, *Chilomastix* and a few *Enteromonas*. Besides, there were scanty *E. histolytica* and *E. coli* cysts. She was immediately put on to atebirin (one tablet three times a day for 5 days). Stools were examined daily during treatment and on the 7th, 11th, 15th, 18th, 24th, 30th and 36th day after the treatment had been completed. *Giardia* disappeared after 6 doses of atebirin and were not found any time during these examinations. But all the other flagellates and the amœbæ remained unaffected. A course of emetine injections, however, brought about the disappearance of *E. histolytica* from the stool.

Case 2.—D. C. complained of long-standing diarrhoea alternating with constipation and abdominal discomfort, especially after food. Stools positive for *Giardia* cysts (heavy infection). Put on to atebirin. Stools were examined daily during treatment and on the 7th, 13th, 20th, 29th and 32nd day after treatment. Administration of 5 tablets only, caused the disappearance of the flagellate from the stool. Stools were also plated on McConkey's lactose neutral-red agar but no non-lactose fermenters were isolated. Diarrhoea stopped and the patient's health gradually improved.

Case 3.—M. B. A child of 8 years. There is a history of the passage of voluminous stools containing large quantities of mucus for nearly 4 months. Marked emaciation and tumidity of abdomen. Stools showing large number of *Giardia lamblia* (chiefly trophozoites). Atebrin was given in proportionate doses. There was rapid disappearance of the parasite. After 3 doses very scanty parasites were found and after the 4th not a single flagellate could be discovered in spite of prolonged search. Repeated examinations during and after treatment for two months failed to show the flagellate in the stools. Symptoms disappeared and the patient's general condition greatly improved. Three samples of stools were plated for pathogenic bacteria, one gave a culture of *B. pseudocolinus*. But no importance was attached to this finding as the patient showed marked improvement on atebirin.

Case 4.—A. R. A case of oriental sore. There is no history of any intestinal disturbance. Stools positive for *Giardia* and *E. coli* cysts. Put on atebirin. Stools were examined every day during treatment and on the 4th, 15th, 22nd and the 30th day after treatment. *Giardia* disappeared after 9 tablets had been taken. The drug had no effect on *E. coli*.

Case 5.—M. D. A long-standing case of *Giardia* infection. Occasional attacks of diarrhoea accompanied by pain about the umbilicus. There is marked flatulence; stools showed a good number of the encysted flagellates. Proved refractory to stovarsol and bismuth. Put on to atebirin which brought about a rapid disappearance of the parasites from the stool. Repeated examinations (three times during and nine times after treatment) failed to reveal the parasites. There was definite improvement of the patient's condition with the eradication of the parasites.

Case 6.—B. D. A girl of 18, suffering from asthma associated with abdominal symptoms. Stools showed the cysts of *Giardia lamblia* and *Entamoeba histolytica*, was treated with atebirin, followed by a course of carbarsone. Both the infections were eradicated. Six consecutive examinations after the completion of atebirin and carbarsone treatments were negative for both *Giardia* and amoeba. Although the patient's general health improved and abdominal symptoms passed off, she was not cured of asthma.

Case 7.—P. B. The patient is a railway doctor. Was suffering from giant urticaria for a month and a half. The stool showed a heavy infection with *Giardia*. There was no history of any intestinal trouble. Five tablets of atebirin caused the disappearance of the flagellate from the stool. The patient felt that after he had received a full course of atebirin treatment the severity of the urticarial eruptions was lessened. Examination of stools were carried out at weekly intervals, the last being done 29 days after the completion of the treatment. All these specimens were negative for *Giardia*.

Case 8.—K., aged 2½ years. History of persistent diarrhoea. Was treated with 'Inteste Phage' (A. F. D.), castor oil emulsion, bismuth with salol, etc., but to no purpose. Stools showed a large number of *Giardia*, chiefly trophozoites. At once put on to atebirin. After 3 days' treatment the parasites disappeared from the stool and diarrhoea stopped. Stools were examined 23 times after treatment, but they were invariably negative.

Case 9.—R. C. A case of chronic malaria (benign tertian) with enlarged spleen. No history of any recent bowel disorders. Stools positive for *Giardia* cysts. A course of atebirin caused the disappearance of the parasites from the stool. As daily specimens were not available it was not possible to state after how many doses of atebirin the parasites had disappeared. Several examinations after treatment failed to show the parasites.

Case 10.—T. M. History of recurrent diarrhoea and pain in the abdomen for two years. All six serial examinations of stools showed the cysts of *Giardia* in large numbers. Atebrin was given. Several examinations after a full course of atebirin had been taken were carried out covering a period of a month and a half. On no occasion was the flagellate ever found. The patient's condition improved very definitely after treatment.

Remarks.—It will appear from the foregoing that the parasites in all cases disappeared after the administration of 9 tablets of atebirin as a maximum. These cases were kept under observation for a minimum period of six weeks after the treatment had been discontinued. During and after this observation period the stools, examined several times, were invariably negative for *Giardia*. In a case of very long duration and showing large numbers of the parasites in the stools the infection was eradicated with remarkable rapidity (case 3). Some cases showed a mixed infection with flagellates of other genera and amoebae (cases 1, 4 and 6). Atebrin does not seem to affect these flagellates, e.g., *Trichomonas*, *Chilomastix* and *Enteromonas*. Nor has it any action on *Entamoeba histolytica* or *Entamoeba coli*. The question of pathogenicity or otherwise of *Giardia lamblia* is still awaiting solution. Some observers consider that, like other intestinal flagellates, this parasite is also a harmless organism. Their contention is that the infection—and often a heavy one—is frequently found in perfectly healthy individuals

and not associated with any symptoms. Further, *Giardia* infections are very common in animals, e.g., quite a large proportion of rats and mice harbour *Giardia muris* and in such animals no lesions of the gut are to be discovered. It lives in the fluid contents of the gut and does not possess the power of invading tissues. Others who lay claim to its pathogenicity argue that the mere fact that *Giardia* infection can be seen in healthy persons does not prove its non-pathogenicity, for quite a large number of apparently healthy individuals harbour *E. histolytica* infection. As a result of their clinical observations they are inclined to hold that *Giardia* often causes diarrhoea alternating with constipation, abdominal pain, flatulence, etc. Children are the worst sufferers; in them there may be intractable diarrhoea associated with the passage of large quantities of mucus and impairment of growth as a result of chronic indigestion. Some observers even go so far as to incriminate this flagellate as the cause of cholecystitis, although they cannot furnish any satisfactory evidence to show that the flagellate can spread from the duodenum to the gall bladder. In our series of 10 cases 3 had no intestinal disturbance, 2 had associated *E. histolytica* infection, and the abdominal symptoms complained of by them may be attributed to this. In the remaining cases repeated examinations showed no other abnormality than a heavy infection with *Giardia* and their symptoms ameliorated or disappeared with the eradication of the infection. In the circumstances it is not perhaps unreasonable to assume that *Giardia* infection was the cause of the symptoms in these cases.

Summary

Ten cases of infection with *Giardia lamblia* have been treated with atebirin using the same dose as for the treatment of malaria. Administration of 9 tablets as a maximum brought about the disappearance of the parasites from the stool in every case. Repeated examinations of the stools after treatment up to six weeks or more failed to show the parasite. Although atebirin has proved invaluable for the eradication of *Giardia* infection, it does not possess any action on other flagellates of the intestine, e.g., *Chilomastix*, *Trichomonas* and *Enteromonas*. Nor does it affect *Entamoeba histolytica* or *Entamoeba coli*. The question of the pathogenicity of *Giardia* is discussed and the authors are inclined to the view that in some cases at least infection with *Giardia lamblia* is responsible for intestinal disturbances, especially in children.

DIFFICULTIES AND DANGERS IN PROVIDING DONORS OF BLOOD

By S. D. S. GREVAL

LIEUTENANT-COLONEL, I.M.S.

Imperial Serologist, Government of India,

and

S. N. CHANDRA

CAPTAIN (late I.M.S.)

First Assistant

(Imperial Serologist's Laboratory, The School of Tropical Medicine, Calcutta)

THIS communication is published in the interest of the newly established or proposed depôts for blood transfusion, which are being organized in several Provinces in India by the Provincial Red Cross Societies or other bodies. A blood transfusion service has been run for Calcutta from this laboratory for the last 15 years.

The accompanying diagram explains the serological constitution of blood groups and blood types, and gives the equivalents of O, A, B and AB in the old terminology which should now be forgotten.

I. Donors of the same group yet incompatible

1. *Abnormal constituent in the serum due to a morbid state.*—Lloyd and Chandra (1933) recorded an AB recipient whose serum agglutinated red blood cells of AB subjects, A subjects and B subjects. There was an urgent need for transfusion of blood which was given successfully from an O donor.

Neter (1936) recorded an O recipient whose serum agglutinated the red blood cells of a number of O subjects. The recipient had previously three blood transfusions without abnormal reactions. The abnormal iso-antibody disappeared during the course of the disease (sub-acute infective endocarditis).

2. *Coagulation of the recipient's blood on exposure.*—Another difficulty often encountered is that the recipient's blood, one drop + the donor's blood one drop, with or without a drop of saline, on a slide, 'agglutinate'. The fact is that the recipient's blood coagulates on exposure to air. Presence of normal blood appears to contribute to the process. A case illustrating this difficulty occurred in one of the local hospitals a few months ago. The blood of the prospective recipient, a very bad case of anæmia and belonging to group A, was 'agglutinating' the red blood cells of every available group A donor, when matched directly, as described. When the recipient's serum was separated from a few drops of blood it did not agglutinate the red cells of any of the prospective donors of the same group. A successful transfusion was given and a rapid improvement in the patient's condition followed.

Short cuts in hæmagglutination are to be deprecated. The washed red blood cells (not

whole blood) and separated serum (not plasma) of the donor and the recipient should be tested against known sera and cells, and cross-matched.

3. *An antiserum formed in the recipient's blood against the serum proteins of the donor after a previous transfusion.*—Gyorgy and Witebsky quoted by Neter (*loc. cit.*) have recorded a case. The iso-antibodies in the recipient's serum against the donor's serum

Blood groups

Jansky	Moss	New
I	IV	O
II	II	A
III	III	B
IV	I	AB

A and B are the iso-hæmagglutinogens.

a and b are the corresponding iso-hæmagglutinins.

The group is named after the iso-hæmagglutinogens.

The four groups indicate the only four possibilities, compatible with life, in which the iso-hæmagglutinogens and the iso-hæmagglutinins can co-exist in the same subject. In a 'defective' group an iso-hæmagglutinin which can exist compatibly with life is absent (e.g., A, a; A, o).

Further division of A into A₁ and A₂ (and into A₁B and A₂B) increases the number of groups to six.

Quite unrelated to A and B are the hæmagglutinogens (not iso-hæmagglutinogens) M and N. They occur as M, N, or MN in all subjects of all groups. No subject is free from them. They differentiate three types in each group and thus make possible 12 descriptions of blood, if only the original four groups are considered, or 18 descriptions, if sub-groups with A₁ and A₂ are also considered. A blood may be:—

OM	ON	OMN
AM	AN	AMN
BM	BN	BMN
ABM	ABN	ABMN

A₁ and A₂ are of no significance in transfusion of blood. They are even ignored in forensic medicine by many workers because of difficulties of technique. M and N have great forensic value and, as is suggested in this paper, also a place in transfusion of blood.

could be demonstrated by skin test and complement fixation. Possibility of such a reaction should be excluded when a donor is used twice for the same recipient. We recommend precipitin reaction and skin test.

4. *Naturally occurring agglutinins in a recipient's blood against M type cells.*—At least one case of a naturally occurring anti-M agglutinin has been recorded (Wiener, 1935). A direct matching of the bloods of the donor and the recipient of the same group will eliminate the danger of an accident due to this cause.

5. *Agglutinins formed in the recipient, against M type and N type cells, after a previous transfusion.*—Such occurrences are well within the range of possibility. They cannot be excluded in Neter's case, as the serum was not tested with known OM and ON cells. A direct matching of the blood will eliminate the danger of an accident.

6. *Incompatibility of white cells and platelets.*—Snyder (1929), going by the work of Doan and his own surmise, contemplated creating more work for the serologist. Further observations on the subject have not been encouraging. Exclusion of these incompatibilities need not be undertaken.

II. Dangerous universal donors

The 'universal donor' belongs to group O. He has no iso-hæmagglutinin in his red blood cells but has both the iso-hæmagglutinins a and b in his plasma. His red cells cannot be agglutinated by any recipient's plasma; but his plasma, if its titre of a and b is high enough, can kill recipients of all other groups by agglutinating their red cells.

De Bakey and Honold (1938) draw attention to Hesse's statement that 'the transfusion of blood from a universal donor with a titre of 1:16 causes no symptoms but in cases with higher titre signs of hæmolytic shock are likely to occur'. The original publication is not available. The term titre in serological usage sometimes denotes the highest initial dilution of the serum used in putting up a test which yields results (e.g., titre of hæmolytic amboceptor and titre of complement) and sometimes the highest ultimate dilution reached in a test which yields results. The same term in bacteriological usage always denotes the highest ultimate dilution of the serum reached in a test which yields results. In titrating the iso-hæmagglutinins, equal quantities of the serum dilution and the red cell suspensions (usually 2 per cent) are mixed in putting up the test. We err on the right side and call 'universal donors of the first choice' only those group-O donors whose serum does not agglutinate red blood cells A or B in an initial 1 in 16 dilution. By all calculations based on the minimum dilution of the donor's plasma in the recipient's blood and on the minimum concentration of the recipient's red cells, donors of this titre are perfectly safe. A margin

also exists for the occasional variation of titre in the same subject.

This standard compares very favourably with the recommendation of Levine and Mahec (1923) 'that in performing the direct matching test of Coca (1918) the donor's citrated blood be diluted with saline 2:10 instead of 1:10 before mixing with the equal volume of recipient's citrated blood.' In the resulting procedure the donor's plasma in a 1 in 10 dilution (only half of the whole blood is plasma) reacts with the recipient's red blood cell, concentration of which may vary from 10 per cent (in a case of severe anaemia with a red cell count of only 1 million) to 50 per cent (in a case with a red cell count of 5 millions). A 1 in 16 dilution of a serum reacting with a 2 per cent suspension of red blood cells is more effective than a 1 in 10 dilution reacting with a 10 to 50 per cent suspension.

Even a 1 in 25 dilution of serum reacting with a 2 per cent suspension of red blood cells is more effective than a 1 in 10 dilution of serum reacting with 10 to 50 per cent suspension. The donors whose sera react with a 2 per cent suspension in a 1 in 16 dilution but not in a 1 in 25 dilution we call 'universal donors of the second choice'. Their blood can be transfused in much smaller quantities than the usual dose. Two hundred c.cm. should not be exceeded in the case of an adult.

In determining the range of the iso-hæmagglutinin titre of the population of Calcutta (unpublished work) we found that out of 37 subjects of O group:—

- Twelve conformed to the standard of the universal donors of the first choice;
- Eight conformed to the standard of the universal donors of the second choice;
- Eleven went beyond the range of safety; their serum agglutinated r.b.c. in a dilution of 1 in 25;
- Four were dangerous; their serum agglutinated r.b.c. in a dilution of 1 in 50; and
- Two were almost certain to cause serious accidents; their serum agglutinated r.b.c. in a dilution of 1 in 100.

Only the first 20 were 'universal donors', the last 17 were simply group-O donors.

Our dilutions were 1 in 100, 1 in 50, 1 in 25, 1 in 16, and 1 in 12. They were made as follows:—

(i), 1 drop from a calibrated pipette delivering 50 drops to 1 c.cm. + 1 c.cm. saline = 1 in 51 = 1 in 50 (approx.). Two drops of the dilution, from the standard pipette were used in testing against known cells A and cells B.

If agglutination appeared with dilution (i),

(ii), dilution (i) doubled by adding 1 c.cm. of saline = 1 in 100 (approx.). Two drops were tested as before.

If agglutination did not appear with dilution (i),

(iii), 1 more drop of serum added to dilution (i) = 2 in 50 or 1 in 25. Two drops were tested as before.

If agglutination did not appear with dilution (iii),

(iv), 1 more drop of serum added to dilution (iii) = 3 in 49 = 1 in 16 (approx.). Two drops were tested as before.

If agglutination did not appear with dilution (iv),

(v), 1 more drop of serum added to dilution (iv) = 4 in 48 = 1 in 12.

We consider this scheme of dilution particularly well suited to the titration of the iso-haemagglutinins. From the total bulk of fluid the outgoing quantities used in testing are looked upon as saline only, the small amount of serum in them being ignored. All the necessary dilutions are made by modifying the contents of one tube only. The gaps between the low dilutions are smaller than in the usual geometrical series, 1 in 2, 1 in 4, 1 in 8, 1 in 16, 1 in 32, 1 in 64, 1 in 128, etc.

In medical cases, whose physiology is below par, we discourage the use of universal donors. Their blood introduces into the system of the recipients iso-antibodies which are foreign to the latter's serological constitution and need elimination. In certain morbid conditions, however, the universal donor may be the only compatible donor.

It must be realized that all group O subjects are not universal donors.

III. Dangerous A and B donors for universal recipients

The 'universal recipient' belongs to group AB. He has the iso-haemagglutinogens A and B in his red blood cells but no iso-haemagglutinins in his plasma. His plasma cannot agglutinate any donor's cells but his red blood cells can be agglutinated by donors of all other groups if the titre of their iso-haemagglutinins is high enough.

The percentage of AB subjects being small donors are not easy to find. Generally an A or a B donor is provided. An O donor can also be provided. The titre of the iso-haemagglutinins a and b should conform to the standard discussed under II.

As a rule the titre of a and b is lower in B and A subjects than in O subjects.

IV. Wrongly grouped donors

Red blood cells of certain subjects of groups A and AB react slowly with sera a. If only the cells are grouped and not watched for a sufficiently long time (30 minutes) they are likely to be returned as O and B.

There are reasons to believe that there are slowly reacting subjects of group B and AB too.

The dangers arising from wrong grouping are effectively guarded against when both the cells and the serum are tested in grouping.

V. Aged and diseased donors

The age should as a rule be 20 to 36. Exceptions can be made in the case of well preserved subjects over 36. Prejudice against women donors is ill founded.

A rigid physical examination of the donor and enquiry into his history is enough to guard against transmitting disease to the recipient. A blood film may have to be examined. Allergic conditions and asthma in the donor are likely to cause immediate accidents. Wassermann reaction is usually done as a routine. Pre-chancere stage of syphilis can be excluded by absence of risky exposure during the previous 6 (for all practical purposes) to 12 (for absolute exclusion) weeks. Anaemia should be particularly excluded.

VI. Use of human immune serum from convalescent cases

Can serum from suitable recovered cases of an infectious fever be given intravenously to fresh cases of the same fever regardless of the blood group? Recently we had occasion to use such serum intramuscularly in smallpox. It could be used intravenously, too, subject to the same condition of titre as discussed under *Dangerous Universal Donors*. The same remarks apply to other human immune sera.

VII. M and N in transfusion

It is known that certain donors of blood are better suited for a recipient than others. Are they of the same type as the recipient? Should not the compatibility of both group and type be an important consideration in serious morbid states (such as severe anaemias, toxæmias and bacteræmias) in which a reaction is to be feared?

The technique of typing is as easy as that of grouping (Grevall *et al.*, 1939). The typing fluids, anti-M and anti-N, however, are difficult to prepare and expensive to purchase from commercial firms. All the recipients and the donors, therefore, cannot be typed as a routine.

VIII. Can a donor be used in emergency without a Wassermann reaction test?

Some time ago, for a bleeding case of enteric fever a donor could not be found until the evening. As his Wassermann could not be done the same evening he was asked to come for service next day in the afternoon. In the meantime the patient died. We hold that under such circumstances donors should be used if found fit on physical examination. Syphilis, if it occurs, can be treated later. Men marry, insure their lives and join the defence forces of the State without knowing their Wassermann reaction. Detection of syphilis in the male by means other than serological is not a difficult task.

IX. Can small quantities of blood be transfused without grouping?

The answer is no, although Nandi and Mukherjee (1930) in Calcutta claimed to have

disregarded grouping in giving 30 to 40 c.cm. of blood intravenously and repeatedly to many patients on many occasions.

Severe reactions have resulted from 10 c.cm. of blood given intravenously (Wiener, *loc. cit.*, page 56). Recovery, however, has been possible after a reaction following transfusion of less than 100 c.cm. of incompatible blood (Snyder, *loc. cit.*, page 43).

X. Can infants be transfused safely without grouping?

The answer again is no. Although the iso-agglutinins in infants are usually absent every infant cannot be presumed to be a universal recipient. Besides, the iso-agglutinins though absent at the time of the transfusion may develop later.

Transfusion from a safe universal donor can of course be given.

XI. Can grouping be disregarded in intra-peritoneal transfusion?

The answer once again is no. The blood from the peritoneal cavity is absorbed into the general circulation very rapidly.

XII. Can grouping be disregarded in giving injections of blood intramuscularly or subcutaneously?

The intramuscular and the subcutaneous injections have also been called transfusion of blood. It is better, however, to restrict the term transfusion to (i) intravenous, (ii) intracardiac and (iii) intraperitoneal injections of blood.

Small quantities of blood not given for purposes of increasing the volume of blood in the body, such as have been recommended for controlling hæmorrhages in infants, are given regardless of the group. The same considerations hold for immune human serum and adult serum given in small quantities, such as is done in aborting or modifying measles.

For larger quantities of blood given to infants, intramuscularly, to increase the volume of blood in the body, the group should be determined. But a safe universal donor may be used regardless of the group of the infant.

For giving large quantities of immune human serum, which are likely to increase the volume of blood in the body the group should be determined. But a pooled serum conforming to the standard of the safe universal donor (a 1 in 16 dilution not agglutinating or just agglutinating cells A and B) may be given.

XIII. Donors versus stored blood

The donors are often difficult to find while stored blood is available within a few minutes. 'Experimental work has established the safest maximum length of time in which the blood can be utilized as 10 days, with some investigators extending the period of therapeutic usefulness even to 30 days' (De Bakey and Honold, *loc. cit.*). In our experimental work, not connected

with therapeutics, we have injected into animals, human blood stored for over 2 months. When the demand for the stored blood is well established the storage need not exceed a few days. Human blood stands storage much better than sheep's blood with which all serologists are acquainted in connection with complement fixation reactions. The storage is said to decrease allergic reactions.

A scheme for stored blood has been recently suggested in the *Lancet* (15th October, 1938, p. 922).

Blood banks, of American nomenclature, can be run by the Red Cross Societies in big centres in India. The donors will donate blood free for their relations and friends. Mr. Smith will donate for Mrs. Smith and Mr. Brown for Mrs. Brown. If Mr. Smith's blood is not compatible with Mrs. Smith's blood but Mr. Brown's is, then, Mrs. Smith will receive Mr. Brown's blood. Mrs. Brown can receive Mr. Smith's blood, if compatible, or some one else's who has also donated free for his relation or friend. Same arrangements will hold for male relations and friends.

The same bank can also buy and sell blood, on a humanitarian basis, making enough profit to pay for the overhead charges of the establishment. The blood can also be given free to the poor who will give to the bank presents in cash, according to their means, on recovery. Full blooded subjects will come to the bank for blood letting.

The staff employed by the blood bank will have excellent opportunities of research on blood, to finance which organizations interested in research in India can be approached.

Only the stored blood can definitely bring the transfusion of blood within the reach of all cases of accident and hæmorrhage in childbirth, and all poor patients.

The stored blood will not do away with the providing of donors, altogether. Fresh blood and fresh unaltered blood, as opposed to citrated blood, will always remain in demand. Advance in immunology may even increase the number of donors by adding to them specially prepared donors.

With the details of collecting blood; testing, grouping and matching donors; keeping records; supplying blood; and receiving cash, this communication is not concerned. General observations, however, may be made concerning three innovations: (i) cadaveric blood which coagulates and 'disagulates' and has been used in Russia, (ii) preserved and sealed blood used in the Spanish Civil War, and (iii) blood derived from the placenta of healthy parturient women (from the cord—baby's blood. S. D. S. G.) (De Bakey and Honold, *loc. cit.*). To say the least, the processes are messy, risky and uncharitable. Given adequate organization, there is no dearth of blood collected and given or preserved under ideal conditions in any country or community, under any conditions of peace and war.

XIV. Risk incurred by donors

In the hands of a competent operator a donor runs no risk. An able-bodied man or woman of the right weight for height and age can easily part with at least 500 c.cm. of blood. An hour suffices to recover from any possible feeling of faintness, a day or so to make up the volume of blood in the body, and a week or so to make up the number of red corpuscles per c.mm. An average donor can safely donate 500 c.cm. of blood every four to six weeks.

We have a record of over 1,200 recipients whom we have supplied with donors. Not a single complaint has ever been received from any of the donors. Some of our donors, military medical students of the Calcutta Medical College, donate blood repeatedly for 5 years, without any ill effects. They are examined at frequent intervals for physical fitness, etc.

The age limit of 20 to 36 for donors, exceptions being made for well preserved subjects over 36, has been suggested more in the interest of the donor than of the recipient. There is very little danger of inadequate blood regeneration during this period.

The prejudice amongst Indians against becoming professional donors is mostly a social question. The sale of life's blood brings discredit on the family. Free donations would be easier to obtain if proper organizations existed to receive them. Such organizations once started would remove the prejudice too in a quiet way and would soon be taken over by commercial enterprises, as is occurring in the West.

Summary

1. A diagram explains the serological constitution of the blood groups (O, A, B and AB) and the types (M, N and MN).

2. Donors of the same group may be found to be incompatible on direct matching of bloods.

3. All group-O donors are not universal donors. Only those whose serum in a dilution of 1 in 16 does not agglutinate or just agglutinates cells A and B are, and should be called, universal donors of the first and the second choice.

4. All group A and B donors are not safe donors for the universal recipient. Only those whose serum in a dilution of 1 in 16 does not agglutinate or just agglutinates cells A or B are.

5. A weak A is responsible for wrong grouping. There may be a weak B too. The reactions should be watched for 30 minutes. The danger of wrong grouping is eliminated when both the cells and the serum are tested.

6. Disease in the donor is excluded by a rigid physical examination, scrutiny of history and possibly examination of a blood film. Allergic conditions are the real danger.

7. Human immune serum from convalescent cases can be given intravenously, subject to the same conditions as the blood of a group-O subject.

CHORDOMA

By M. N. DE, M.B. (Cal.), M.R.C.P. (Lond.)

*Professor of Medicine, Medical College, Calcutta, and
First Physician, Medical College Hospitals*

and

B. P. TRIBEDI, M.B. (Cal.), D.B. (Lond.)

*Professor of Pathology and Bacteriology, Medical
College, Calcutta, and Bacteriologist to the
Government of Bengal*

(From the Department of Pathology and Bacteriology,
Medical College, Calcutta)

CHORDOMA is a tumour growth which arises from the remnants of the embryological notochord. Though its occurrence has been recorded in the past in considerable numbers, this type of neoplasm still remains rather a rare condition in the course of routine morbid histological diagnostic work.

The notochord gives rise to a tissue which has often been called cartilage. The notochordal tissue however differs from the typical cartilage

(Continued from previous column)

8. Haemagglutinogens M and N also deserve a consideration in transfusion.

9. A donor, if compatible and fit, can be used in emergency without a Wassermann test.

10. Blood should never be given intravenously without grouping, however small the intended quantity may be.

11. Infants cannot be transfused safely without grouping.

12. Grouping cannot be disregarded in an intraperitoneal transfusion.

13. Grouping can be disregarded in giving blood subcutaneously or intramuscularly, if the blood so given is not likely to increase the volume of the blood in the body immediately.

14. Stored blood can also be used for transfusion. In fact it is only the stored blood which will bring transfusion of blood within the reach of all cases of accident, hæmorrhage in childbirth, and poor patients who cannot afford to pay professional donors.

15. In the hands of a competent operator a donor runs no risk. An average donor can safely donate 500 c.cm. of blood every four to six weeks.

structure. Williams (1908) described the principal stages in its development in the pig. The human notochord undergoes a development similar to that of the pig. After it has ceased to be an epithelioid rod of cells, its most characteristic feature is that it includes a portion of the nucleus pulposus. The notochordal tissue forms a vacuolized syncytium suspended in a gelatinous matrix, which, at the periphery of the nucleus pulposus, is bounded by a structureless membrane. The notochord is rarely a source of tumour formation, but, when it does give rise to one, this is composed of tissues similar to those normally found within the nucleus pulposus (Lewis and Bremer, 1927).

Stewart (1922), who described the first case in the British Isles and also gave an historical review dated from 1856 on the subject, recorded the published cases and discussed the morbid anatomy, histology and the clinical manifestations of this type of neoplasia. Coenen (1925) and Stewart and Morin (1926) recorded further cases of this type of neoplasia. Cappell (1928) while describing chordomas studied the embryology of the notochord in the human subject and observed certain aberrations of development of this tissue. Machulko-Horbatzewitsch and Rochlin (1930) described notochordal tumours and Mabrey (1935) recorded his observations on the study of 150 cases of this type of tumour. Dickson, Worster-Drought and McMenemey (1937) described a case of spheno-occipital chordoma and discussed its histology in detail.

Considering the rarity of these tumours a case of chordoma that we have observed is recorded below :—

K. F., male, aged 42 years, mason by occupation, came to the hospital on 7th January, 1937, for a growth on the lower part of his buttock. Four years back a small swelling about the size of a bean appeared over the sacrum posteriorly. This was slightly painful and tender. The size increased slowly and a globular mass of 2 inches in diameter appeared. He carried on his job without any inconvenience but 15 days before his admission he was gored by a bull and injured at the site of the tumour. After this incident the tumour increased rapidly and began to hang as a pendulous mass.

On examination.—A swelling 4½ inches in diameter was noticed in the lower part of the sacrum and coccyx. Skin over the swelling was tense, shining and hot. The mass was found to be fixed to the underlying structures. Rectal examination revealed no protruding mass. There was only slight tenderness over the posterior wall of the rectum in the lower part. X-ray examination showed complete destruction of the coccyx. No bone reaction was seen and the lower two-thirds of the sacrum were missing. The tumour was removed by operation on 25th January, 1937, and it was observed that though it was attached to the rectal wall it was completely separate from it.

The mass as obtained from the operation showed the following: The tumour was a globular mass, oval in shape and measured 5½ by 4 inches. The cut surface of the tumour mass was noticed to be partitioned into a number of areas of different sizes, sharply demarcated by bluish-white and grey strands. These circumscribed areas were composed of pale yellow, brown and red masses. At certain places, there were actual hæmorrhages, recent and old. The whole of the cut surface presented a gelatinous mucoid appearance which was a very marked feature (plate XIV, figure 1).

The histological picture of the tumour presented columns of cells, fibrous tissue strands and mucoid areas (plate XV, figure 2). On higher magnification most of the cells showed the typical cytoplasmic vacuolations (plate XV, figure 3). These physaliphorus cells were a marked feature in all the blocks that were studied. On still higher magnification the characteristic nuclear vacuolations, diffuse and circumscribed, could be seen clearly (plate XV, figure 4). At certain areas the cellular element was altogether deficient but extensive mucoid areas, as seen in plate XV, figure 2, were found.

The patient made an uneventful recovery and after the wound healed up he was discharged from the hospital on 21st March, 1937. He was traced and examined on 15th February, 1939. As to the general condition he was fairly well and carrying on his work as usual. On examination of the site of the tumour it was noticed that a globular mass, the size of a hen's egg and soft in consistency, had appeared half an inch below the scar mark of the last operation (figure 5). For the last six months he noticed this swelling which

Fig. 5.—Photograph showing the recurrence of the tumour *in situ* just below the old operation scar.

was very slowly increasing. He had no local complaints whatsoever and was inclined to ignore the recurrence.

Comments

The case under review corresponds in most points with the previously reported cases. It is interesting to note that the patient had no complaint except that of a hanging mass, and, though the tumour was attached to the rectal wall, it did not invade that structure. The greater incidence of this type of tumour in males brings up the question of trauma (Mabrey, 1935). In the present case there is definite association of trauma which at least aggravated the condition. Figure 5 clearly suggests a small recurrence immediately below the old scar. The prolonged course for over five years did not produce any marked effect on the patient's general condition which indicates the low grade of malignancy of this neoplasm.

Our thanks are due to Professor M. J. Stewart, Leeds, for confirming the histological diagnosis

ON CERTAIN CYCLICAL CHANGES OBSERVED IN THE BLOOD PICTURES OF CASES OF UNTREATED ANÆMIA COMPLICATING PREGNANCY IN TEA ESTATE COOLIES*

By K. P. HARE, M.B., B.S.

Hooghrija

Introduction.—In a paper on anæmia in tea garden labour forces, Napier (1937) stated, in support of a plea for the early administration of iron to pregnant women, that 'there is some evidence that these microcytic anæmias become macrocytic during the later months of pregnancy'. The evidence mentioned was not stated in that paper and a search of the scanty literature dealing with the subject has failed to reveal, either a repetition of the statement, or any evidence on which such a statement could be based†.

* Read before British Medical Association at Shillong, 11th March, 1939.

† The statement was based on the observation that amongst 100 labourers, male and female (early pregnancy not excluded), there were only 5 cases of 'hyperchromic anæmia' (Napier and Das Gupta, *I. J. M. R.*, 24, 855), whereas amongst pregnant women of the same population the incidence of 'hyperchromic anæmia' was about 33 per cent (Napier and Bilimoria, *I. J. M. R.*, 25, 529). In the latter series hypochromic anæmia predominated markedly in the early months of pregnancy, whereas in the last trimester about 50 per cent were hypochromic. In both series, though emphasis was laid on hæmoglobin content rather than size, the words 'macrocytic' and 'microcytic' could be substituted for 'hyperchromic' and 'hypochromic', respectively, without altering the truth of these observations.

Such evidence, though not conclusive, carries more weight than the negative findings in the six essentially hypochromic cases reported in the present paper. The subject is still open for further investigation.—L. E. N.]

Now this statement is not only of academic interest, nor is it of interest purely as a basis on which to initiate prophylactic measures. If such a change from microcytic to macrocytic anæmia does in fact occur, a knowledge of the time of its occurrence and the character of the change would be more than likely to provide some evidence of an epidemiological nature on which an hypothesis as to the reasons for the change could be based. I therefore felt that evidence of a positive nature should be searched for, hoping that, if the statement were proved to be true, the epidemiological evidence would also emerge on analysis and our search for the true cause of the deadly macrocytic type of anæmia would take another step forward.

I therefore set myself the task of examining, at monthly intervals during their pregnancy, such anæmic women, spotted by near-by garden assistant medical officers, as were found to be in the early stages of pregnancy. The examinations carried out were as follows:—

- (1) A full clinical examination,
- (2) examination of the urine for albumin and sugar,
- (3) examination of the stools for helminthic ova,
- (4) estimation of hæmoglobin with the Sahli instrument,
- (5) red and white cell counts,
- (6) estimation of cell volume percentage of the blood using Napier's technique,
- (7) calculation of the usual mean corpuscular values,
- (8) examination of a stained blood film.

Fuller details regarding technique have been given in a series of papers dealing with other investigations into problems of anæmia which I hope will appear in the *Indian Journal of Medical Research*.

The series of cases on which this paper is based was dealt with during the latter half of 1938 and was in the nature of a try-out for a more ambitious programme on the same lines projected for 1939. I was engaged at the time on another series of pregnant anæmics so that I was only able to spare the time to examine fifteen women and, from the point of view of its conception, the experiment was a failure.

Six of the cases had passed the twenty-eighth week of pregnancy before their first examination (though that did not matter much because none of the six ever showed any tendency to a true macrocytic anæmia); more important, the three cases which did suffer from a true macrocytic anæmia with megaloblasts in the stained films and a high mean corpuscular hæmoglobin (MCH) were macrocytic when first examined at 20, 22 and 25 weeks. None of the remaining cases showed any permanent change from true microcytic to true macrocytic anæmia, or *vice-versa*. Evidence in support of the suggested transformation was, therefore, completely lacking and, from that point of view, we are in the same position as before.

Some observations of interest did emerge, however, and form the basis of the present communication.

The observations reported

Of the fifteen women examined, six fulfilled three main conditions:—

- (1) They were examined at intervals of at least four weeks on at least three occasions before delivery,
- (2) they did not deliver until full-term,
- (3) none of them received any anti-anæmic treatment of any description.

During the progress of the investigation it became obvious that changes were taking place in the blood pictures of these women without any apparent reason and that, taking individual cases, the changes were not always in the same direction. I was, at first, afraid that these

in each case, against duration of pregnancy in weeks, shows that the variations recorded do not occur at exactly the same time in each case though a fair time relation does exist, but that for each mean corpuscular value the majority of the cases show the same type of curve. This particularly applies to the central portion of the curves—that covering the period between the 28th and 36th weeks of pregnancy.

Curves of mean corpuscular volume.—The central portion of five of the curves is of 'V' formation with the low point occurring somewhere between the 28th and 36th weeks of pregnancy. In three cases both the high points are well marked. In one the first examination was too late to catch the first high point and in another, one examination was missed so that the second high point, though suggested by the subsequent post-partum examination, was

M.C.V.

M.C.H.

M.C.H.C.

Three usual mean corpuscular values plotted against duration of pregnancy in weeks.

changes might be merely an indication of faulty technique and would therefore throw suspicion on other observations. But, as these changes occurred in all the cases it seemed more probable that they were real and might be periodic in nature. I therefore plotted the usual mean corpuscular values in each case against duration of pregnancy in weeks and found that in the majority of cases the curves were of the same general form. The similarities were sufficiently marked to render it almost inconceivable that the variations were due to errors of technique. It therefore behoved one to examine these variations in detail to see if any other cause suggested itself.

Examination of the diagrams, which show mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), and mean corpuscular haemoglobin concentration values plotted,

missed. The remaining curve is of reverse 'V' formation, having a high point at the 32nd week and low points at the 28th and 36th weeks. In the majority of cases, then, there was a tendency for the cells to be normocytic about the 28th and 36th weeks of pregnancy with a tendency to microcytosis during the intervening period.

Curves of mean corpuscular haemoglobin.—Here again, the central portion of five of the curves is of 'V' formation and, again, the low point occurs between the 28th and 36th weeks. In one case, as before, the second high point was missed but is suggested and in the sixth case, as before, the curve during the critical period is a reversed 'V' with the high point at the 32nd week. This is the same case which showed a reversed curve for MCV. We may say that there is a tendency, in the majority of cases in

this series, to marked hypochromicity during the period between the 28th and 36th weeks and that round about the 28th and 36th weeks the anaemia tends to be less hypochromic.

Curves of mean corpuscular haemoglobin concentration.—This set of curves is rather more complex. Three of them show the 'V' form during the critical period: one shows a steady rise, and the other two, one of which is the case whose other curves were reversed, show a reversed 'V' form. In other words, the degree of saturation of the red cells with haemoglobin is also variable but its variations do not appear to be subject to a definite law.

Discussion

I have shown that, in the only six cases of anaemia complicating pregnancy which were untreated and fulfilled all the conditions laid down earlier in this paper, variations have occurred in the three main mean corpuscular values. As regards volume and haemoglobin content, all except one case varied in the same manner and, approximately, at the same time. In the remaining case the variations took place at the same time but were in the opposite directions. With regard to corpuscular saturation the variations were irregular.

Now, what is the explanation of this difference? I suggest that the irregularity of the variations in corpuscular saturation is due to the rapidity with which the alterations in volume and haemoglobin content are taking place. The blood, in other words, is in an unstable condition during the latter half of pregnancy.

What is the cause of this instability? We know that the rate of growth of the foetus in *utero* varies with the duration of pregnancy. The figures given by Bourne (1932) and by Jellett and Nadill (1930) for foetal measurements and weight at various stages of pregnancy show that growth is very rapid between the 28th and 32nd weeks and slows down enormously between the 32nd and 36th weeks. I have not, however, been able to discover in the literature available to me any information as to the nutritional needs of the foetus. I suggest that, *pari passu* with the varying rate of foetal growth, these needs may conceivably also vary from time to time. In that case, even if the mother's intake of iron, calcium and the vitamin-B complex remained at a steady level, increased foetal calls for certain substances at certain times might render the intake deficient in one or more particulars. If the views of those workers who support the theory that these anaemias are nutritional in origin are correct, such variations in the effective intake of certain essential blood-forming substances would be sufficient to account for the haematological changes described above.

In any event, whatever may be the cause, I feel that attention should be drawn to the occurrence of these variations owing to their

EXPERIMENTAL MALARIA INFECTIONS IN TWO RACES OF *A. STEPHENSI**

By PAUL F. RUSSELL

and

B. N. MOHAN

This brief note reports some comparative experimental tests of two races of *A. stephensi* Liston, 1901, as to their susceptibility to infection with *P. falciparum* Welch, 1897. The mosquitoes used were: (1) *A. stephensi* (type) and (2) *A. stephensi mysorensis*, as described by Sweet and Rao (1937). Those of the type form were obtained from larvae in our laboratory colony which was started with larvae from some wells in Madras City. Those of the form *mysorensis* were obtained from larvae collected for us by one (B.A.R.) of the authorities whose work led to the separation of this form from the type (Sweet and Rao, 1937) and brought by us from Bangalore to Madras. We did not ourselves make a differential diagnosis.

We fed the mosquitoes in three lots, both races in each lot feeding at the same time on the same carrier and having the same treatment thereafter. In lots 1 and 2 the donor was a girl of 4 years having for the first lot 6 and for the second lot 4 crescents per 100 leucocytes. The donor in lot 3 was a girl of 9 years having 3 crescents per 100 leucocytes at the time the mosquitoes were applied. In lot 2, some mosquitoes

*The experiments reported in this paper were done under the auspices and the support of the International Health Division of The Rockefeller Foundation, co-operating with the King Institute of Preventive Medicine, Guindy, Madras. The authors wish to acknowledge gratefully the assistance of Dr. B. Ananthaswamy Rao, B.Sc., M.B., B.S., M.P.H., Superintendent, Bureau of Epidemiology and Communicable Diseases, Mysore State, who collected *A. stephensi mysorensis* larvae which were brought by the authors from Bangalore to Madras for use in the experiments.

(Continued from previous column)

bearing on the interpretation of the results of treatment of anaemia. All these six cases received no treatment whatsoever yet their blood pictures underwent great changes. Had they been receiving treatment one would have been tempted to claim that the changes were the result of whatever specific treatment had immediately preceded them. To my mind there is a danger in attempting to classify anaemias on a basis of response to treatment when our knowledge of their underlying pathology is so scanty.

TABLE I

Susceptibility of A. stephensi type and A. stephensi var. mysorensis to infection with P. falciparum

<i>Stephensi</i> type	Number dissected	Gut positive	SPOROZOITES		ALL INFECTIONS	
			Number	Per cent	Number	Per cent
Lot I	17	3	9	52.9	9	52.9
* Lot II	2	0	0	..	0	..
Lot III	42	0	16	38.1	16	38.1
TOTALS ..	61	3	25	41.0	25	41.0
<i>Stephensi mysorensis</i>						
Lot I	49	7	17	34.7	18	36.7
* Lot II	16	1	6	37.5	6	37.5
Lot III	24	1	9	37.5	9	37.5
TOTALS ..	89	9	32	36.0	33	37.1

* The two *type* specimens and 7 of the 16 *mysorensis* appeared to have taken only about half the usual amount of blood.

One of the 7 half-fed *mysorensis* had infected glands. The other 6 half-fed *mysorensis* and the two *type* form mosquitoes were negative.

Lot I, except for a few, was dissected on the 9th day.

The exceptions were dissected on the 8th day.

Lot II was dissected on the 9th day.

Lot III, except for 2 mosquitoes of each race, was dissected on the 10th day. The four exceptions were dissected on the 9th day.

were half-fed on account of the restlessness of the donor. All lots were offered 'conservation' feedings on rabbits during the extrinsic incubation period.

Our results are shown in table I. The *mysorensis* form was not obtainable in larger numbers so that our totals were not so great as desired. However, they were sufficient to indicate that both the *type* and the *mysorensis* form could be easily infected experimentally and that they were about equally susceptible. The percentage of sporozoite infections in 61 of the *type* form dissected was 41.0 and in 89 *mysorensis* the figure was 36.0 per cent. If oöcyst infections are counted the infection rate in the *type* form was 41.0 per cent and in *mysorensis* it was 37.1 per cent. We saw no morphological differences in sporozoites in the two races of mosquitoes

Summary

A. stephensi Liston, 1901, (*type*) and *A. stephensi mysorensis* Sweet and Rao, 1937, were easily and about equally infected experimentally with *P. falciparum* Welch, 1897.

IONISABLE IRON IN COWS' AND MOTHERS' MILK

By J. C. PAL, M.Sc.

Department of Biochemistry and Nutrition, Indian Institute for Medical Research, Calcutta

In a series of earlier publications the nutritive values of Indian food-stuffs and dietaries with reference to their vitamin content, protein and more physiologically important minerals, such as calcium, phosphorus and iron, were investigated (Chakravorty, Mookerjee and Guha, 1933; Ghosh, Chakravorty and Guha, 1933; Ghosh and Guha, 1933; Ghosh and Guha, 1934; Ghosh and Guha, 1935; Guha, 1934; Guha and Chakravorty, 1933). These investigations revealed in certain deficiencies of Indian diets in protein, in certain vitamins and in calcium and phosphorus. A study of certain cooked diets obtained from middle class families, students' hostels and hospitals in Calcutta (Pal and Guha, 1937) showed, however, that while there may be an appreciable deficiency in calcium, the consumption of iron seemed to be more than optimum. In a later paper (Roy, Pal and Guha, 1939), it has been found that of the total iron present in the diets analysed, only a small fraction is present in assimilable form. Researches during

recent years have shown that only ionisable iron present in food-stuffs is available for hæmoglobin regeneration. In the present paper, attempts have been made to obtain information about the presence of ionisable iron as percentage of total iron in cows' and mothers' milk. For this purpose, 10 different samples of cows' milk obtained from different sources and two mixed samples of mothers' milk were analysed and the values are given in the attached table.

Experimental procedure

The ionisable iron was estimated by α -dipyridyl method (Hill, 1930; Shackleton and McCance, 1936). Into five wide test tubes graduated at 20 c.cm., and marked A, B, C, D and E, 5 c.cm. of milk were taken, and 10 c.cm. of acetate buffer of pH 5.5 were added to each of them. They were then heated on a water

Discussion and Summary

Ten different samples of cows' milk from a dairy, a local milkman and a local market were analysed. Both the total and ionisable iron present in them are comparable. Only two mixed samples of mother's milk could be analysed, because nearly 100 c.cm. of milk is required for every experiment and it is very difficult to get such a large quantity of mothers' milk. It was found that almost all the iron present in milk is in available form. The average available or ionisable iron content in cow's milk from different sources is 0.635 mg. per 100 c.cm. of milk, which is almost equal to the total iron present in the samples. The mean figure for ionisable iron in mothers' milk is also almost the same as the total iron present and is found to be 0.625 mg. per 100 c.cm. of mothers' milk. Recovery of added iron was 100 per cent.

Ionisable iron in milk

Cows' milk

Source of milk	Serial number	Ionizable iron in mg. per 100 c.c. of milk	Total iron in mg per 100 c.c. of milk	Quantity of iron added	Per cent recovery	Ionizable iron as per cent of total iron
Dairy ..	1	0.6	0.66	0.03 mg.	100	90.9
	2	0.6	0.64	0.03 mg	100	93.7
	3	0.6	0.68	0.03 mg	100	89.9
	4	0.6	0.64	0.03 mg	100	93.7
Market ..	1	0.7	0.71	0.03 mg	100	98.5
	2	0.65	0.68	0.03 mg	100	95.5
	3	0.6	0.62	0.03 mg	100	96.7
Milkman ..	1	0.7	0.715	0.03 mg	100	97.9
	2	0.65	0.66	0.03 mg	100	98.4
	3	0.65	0.665	0.03 mg	100	97.7

Mothers' milk

Eden Hospital ..	1	0.65	0.655	0.03 mg.	100	99.2
	2	0.6	0.61	0.03 mg	100	98.3

bath for 10 minutes and allowed to cool. After that they were filtered and the filtrate made up to 20 c.cm. mark with distilled water and the pH of them was checked. About 0.5 to 1 gm. of iron-free sodium sulphite was added to each tube and a known amount (about 0.03 mgm.) of iron was added to C and D, to test recovery of iron by this method, and allowed to stand over night. On the following day a few crystals of α -dipyridyl were added to A, B, C and D and E served as blank. They were kept over night for the development of colour.

Next day they were compared against standards prepared after Hill (1930). For the estimation of total iron about 75 c.cm. of milk were evaporated to dryness on a water bath. The evaporated mass was ignited and ash taken to solution with diluted hydrochloric acid. From this solution the total iron was estimated by the method previously described (Pal and Guha, 1937).

FIVE YEARS OF ANTI-MALARIA WORK AT BARWADIH RAILWAY SETTLEMENT

By N. AHMED

Divisional Medical Officer, East Indian Railway

General.—Barwadih, a railway settlement on the Gomoh-Sone East Bank branch of East Indian Railway, is 18 miles south-west of Daltonganj. It is situated 348 miles west of Calcutta in the hilly tracts of the Ranchi plateau in the Palamau district of Bihar province. The range of hills to the south of the colony is a branch of the Vindhya.

Physical geography and meteorological data.—Latitude 23.5°, longitude 85°, elevation 900 to 1,800 feet, temperature maximum 108° to 118°, minimum 38° to 32°F., humidity varies from 15 to 20 in the hot weather to 90 during the monsoon. The subsoil water rises from 4 to 6 feet during the monsoon as compared to the summer level of 26 to 30 feet. The humidity of soil is at its height during the four months of the rains. It falls very low in late winter and summer and often rises a little in the early part of spring. The winds are westerly and north-westerly in summer and winter and purely easterly—full of moisture and heat—in the monsoon.

Rainfall.—Average 50 inches in a year, four-fifths of which fall during the monsoon and half of it in July and August and a few showers in winter. Malaria infection and its manifestations always begin three to four weeks after the initial fall of rain. Early and heavy rains used definitely to mean an early and heavy infection but since adequate anti-malaria measures have been taken at Barwadih the increase in rainfall has no adverse effect on the rate and intensity of infection as the comparison of the figures for 1934, 1935 and 1936 shows. The rainfall was 51.74, 36.04 and 60.07 inches respectively but the heavy showers in 1936 did not bring the intensity of 1933 and the malaria figures continued to go down.

Table to show that rainfall has no effect on malaria in a well-controlled area

	YEAR		
	1934	1935	1936
Rainfall in inches	51.74	36.04	60.07
Malaria sickness (new cases).	130	103	101

Telluric conditions.—The soil is porous of 'Morrum' variety interspersed with rock. On the south is a range of hills rising from 500 to

700 feet high, densely wooded. The foothills are covered with light jungle. The open spaces between the hills are under rice cultivation. There are collections of water shaded with overgrowth, bowers of shrubbery and branches of trees.

Site of the railway colony.—The level of the highland at the foothill drops from 50 to 100 feet at places to a plot of land 1½ miles in length east-west and ¼ to ½ mile in breadth north-south. This is the site of the railway colony.

On the north are swamps, cultivated lands and *bustees*. On the west are low-lying land, culverts, a high embankment, swamps, rice fields and a few villages.

Natural drainage.—Natural drainage of the area is by two hill streams. One a fairly big one running east to west about half a mile in front of the station joins with the smaller one on the north-west which in turn drains into the Koel river, three miles west of Barwadih, in the bed of which the storage wells and pumping station for the water supply of Barwadih are located.

Malaria.—According to Christopher's malaria map of India, Barwadih lies in a region known for 'moderate to high endemicity of more or less static character, the intensity depending on local surroundings'. The following description will show how adverse local conditions made it a hyperendemic place:—

The area was originally under rice and maize cultivation having big bunds for catchment and shallow ponds for storage of water for the fields. On the Central India Coalfields railway acquiring the land for construction of a railway line, abandoned and neglected fields and ponds became shallow pools and swamps with weeds and tall grass which served as excellent breeding places for mosquitoes; these found ideal conditions for the primary meal of blood necessary for the oviposition in the large staff of labourers who were engaged upon the construction of the line, and who were living under conditions that made them readily accessible to biting insects by night or day.

After the construction work was over a chain of borrow-pits, excavated land and dilapidated old *kutcha* buildings occupied by the construction staff were left behind and added to the already existing breeding places.

When the East Indian Railway took over the section for working in 1929, we were faced with the problem of housing our staff in one of the most unhealthy parts of the country.

The normal balance of infection was so materially changed by this that malaria broke out in epidemic form in 1930; over 95 per cent of our railway population at this station was found to be infected, the parasitic index was 78 and the splenic index was 95, and Barwadih was rapidly becoming uninhabitable. This state of affairs roused all departments of the railway and within 5 years the parasitic index fell from 76 to 0.7, the splenic index from 95 to 0.5 and

the malaria sickness from 676.9 to 99.5 per mille. The method by which this most satisfactory result was obtained is best described in its two stages, first in 1931 to 1934 when the measures taken were inadequate and spasmodic, and 1934 to 1936 when scientific organization and control was instituted against this disease.

In 1931 the anti-malaria campaign was started in Barwadih, jungle was cleaned, filling of hollows was started, dilapidated buildings were demolished and anti-larval measures were undertaken, a rough malaria survey was performed and the chief enemy was discovered to be *A. culicifacies*; an interesting experiment was also tried this year in the form of 'blanketing' with quinine and plasmochin. The results were encouraging, the splenic index coming down from 95 to 50, the parasitic index from 72 to 24 and the sickness from malaria from 677 to 280 per mille.

In 1932 there was cessation of activity, with the result that the parasitic index rose from 24 to 48 and the sickness from malaria increased from 280 to 445 per mille. The inactivity of this year and its results were a striking object-lesson of the danger of even a temporary cessation of preventive work in a highly endemic area.

In 1933 work started again much on the same lines as in 1931 with the difference that atabrin was first used in treatment, the work of draining the station was continued together with the filling up of low-lying areas, and in October it was decided to 'blanket' with atabrin and plasmochin. Every man, woman and child in the railway colony received a full curative dose of atabrin followed by a full course of plasmochin. This was most thoroughly done by an experienced assistant medical officer and it is in striking contrast to the 'blanketing' supervised later (1937) by an officer who had no experience in this work. The parasitic index was taken before the 'blanketing' and found to be 48, the splenic index was 47, afterwards the parasitic index fell to 6 and the splenic index to 26, the sickness from malaria dropped from 445 to 231 per mille.

In 1934 the second stage of the work started, it was now realized that the measures taken before had been based on most inadequate data, the result of surveys undertaken by inexperienced men, and that it was impossible to expect any permanent benefit from measures founded on such an unsatisfactory basis. Most unfortunately the ignorance even of members of our own profession regarding the cause of malaria adversely affected the results; a statement was made by one of the doctors in charge of the anti-malaria work that 'it is my firm conviction that unless something is immediately done to supply the staff with good filtered water no amount of money spent on any other anti-malaria measures have any chance of success'. As a result of this much time was wasted and much money was

spent in the improvement of what was not at all an intrinsically bad water supply.

The measures now undertaken included a survey by experts, the establishment of a laboratory on the spot and expert advice from the School of Tropical Medicine, Calcutta, and the Malaria Research Institute, Kasauli. I will now detail the results of these measures.

Survey.—(1) A general survey of the colony, surrounding land and villages was done by Dr. Strickland and myself. We found that large-scale operations for filling were not necessary as it was possible to drain every inch of low-lying ground. Indiscriminate deforestation was stopped until the possibility of the existence of sun-breeders, such as *A. maculatus*, could be negated.

(2) A detailed survey was carried out and sectional maps showing the minutest details were prepared. Taking the railway quarters as a centre an inner circle with a quarter-mile radius and an outer circle with a half-mile radius were drawn. Each circle was divided into four quadrants and each quadrant into four sections. All the breeding places found in the colony and half a mile outside it were separately numbered and shown on the sectional maps. Control maps showed various treatments that those breeding places received monthly. Weekly, fortnightly, monthly and annual reports of the work done were submitted regularly.

(3) The splenic index of children under the age of 10 years, in the colony and the surrounding villages, was taken. The estimate of the parasitic index of outsiders could not be taken.

(4) Barwadih had gained such a notoriety for loneliness and bad climate that it was not easy to keep a trained staff for the specialized work there. The first laboratory assistant resigned within 7 days, the second left in 6 weeks and the third is now working. The malaria inspector resigned in 2 months and was persuaded to come back but resigned after 18 months. The new man is still at work.

Engineering.—Most of the filling and levelling operations were done in 1934 before the detailed survey in August. A large tank on the west of the station was filled, subsoil water drains were constructed and thousands of feet of *kutchha* and *pucca* drains were made so that in 1936 there were over twelve thousand feet of excellent *pucca* drain.

Field work—anti-larval measures

Each man in charge of a section started from the centre of his section and systematically treated every breeding place in it. Small holes were filled in, drains were cleaned, such levelling as was necessary was performed and low shrubs, tall grass and jungle were cleared whenever necessary.

Paris green.—We use the 'Genxco' mixer for mixing paris green and soap-stone powder. We have a small measure for paris green and a large

one for soap-stone so made that even a coolie could make a correct mixture.

(2) We made some interesting experiments with Hoyle's and Britway paris green and found 1 per cent mixture of Hoyle's paris green quite sufficient for our work. Britway was not found so efficacious.

(3) 'Junior Savage Duster' was found very handy for small streams, drains and ditches. 'Smith Broadway Duster' and 'Mysto Rotary Blower' both were found very useful for large collections of water. With a few demonstrations and strict supervision in the beginning the coolies are handling these instruments very efficiently.

(4) We found the limitation of paris green distribution during the monsoon. Every fresh shower destroys the film of powder and it is not so efficient as oiling. We therefore rely more on oiling than paris green when the monsoon is very active.

Note.—Two of our coolies at Tatanagar had arsenical dermatitis of the hands due to careless handling in the mixing of paris green with soap-stone. With the 'Genexco' mixer we have had no such accident for the last three years.

Oiling.—We used hydrocarbon, crude oil and crude naphtha till 1935 and it killed larvæ both culicine and anopheline in 48 to 72 hours. In 1936 we used 'Killsall' with crude oil 1 in 20. The effect was excellent. Within one hour the mature larvæ were destroyed and an examination of the treated place after 24 hours showed not a single larvæ alive there. We have found 'Misto Pneumatic Sprayer' for oil a very useful and economical apparatus. It can be handled easily by one man for hours without fatigue. It leaves one hand free and effects great economy in the use of oil.

Anti-mosquito measures

(1) *Spraying of houses with insecticide.*—Tall grass and jungle that grow round the quarters are cut. This deprives mosquitoes of their natural hiding places and they take refuge in the quarters. The trained malaria staff then go to the quarters and efficiently deal with them by closing the rooms and spraying Hick's insecticide. This kills 20 per cent of the mosquitoes outright and makes the rest of them unconscious. After a quarter of an hour dead and dying mosquitoes are collected and destroyed. The trouble of entering *purdah* houses is overcome by appointing a female coolie for the job.

(2) *Railway carriages.*—Railway carriages temporarily stabled at Barwadih were found to become very good hiding places for mosquitoes. They were specially found under the seats. It is worth keeping in mind that railway carriages are one of the means of conveying mosquitoes from one station to another which may be hundreds of miles away. Steps were taken at Barwadih to see that carriages coming in or going out neither became a shelter nor means

of conveying mosquitoes to and from Barwadih and other stations on the line.

(3) *Running rooms.*—The running rooms are all provided with mosquito-proof wire gauze doors and windows with automatically closing hinges. Mosquito nets are also provided for guards, drivers and running men stopping at Barwadih for the night. The employees and their families are all advised to use mosquito nets in their houses.

(4) *Propaganda.*—Propaganda work has also been done to teach people the habits of mosquitoes, the danger that they carry and how to deal with them and their breeding places individually.

Methods of check on the work.—(1) A check on the efficiency of anti-larval measures was made by daily collections of anopheline larvæ from water collections in the area, counting the catches, hatching them out and identifying them. The places where anopheline larvæ were found received daily attention till free and then the usual weekly attention was all that was needed. All these operations were marked on newly-made sectional maps.

(2) A check on the anti-mosquito measures was made by counting the systematic daily catches from the houses and comparing them with the successive ones. If results were unsatisfactory extensive search was made for any undetected breeding place around the quarters.

(3) A general check on the work was done by comparing the results of our catches in the colony with those of our daily catches from the huts of the surrounding villages and *bustees* adjacent to our colony.

Malaria and laboratory work.—Having a well-equipped laboratory and an efficient laboratory assistant we could do systematic and scientific work of identification and dissection of mosquitoes and recording of parasitic index. From 1931 to 1934 we did not even know the actual carrier of malaria of the locality nor could we prove the existence or absence of a *sun-breeder* on which the planning of the nature of our field work depended to a great extent.

Collection of larvæ and mosquitoes (1935 and 1936)

Adults.—There were two catches a day, one in the morning and one in the evening, from the colony and from the surrounding *bustees*. To make a comparative study the *bustee* catches were of great benefit. Eleven *bustees* surrounding the colony were taken into consideration, from each a daily catch would come. Catches were taken one after another in order. Total catches from the colony and the *bustees* were 40,011 out of which about 1,500 were hatched from larvæ. The variation in the incidence month by month was recorded and is interesting and instructive.

Larvæ.—Larvæ were caught from all known varieties of breeding places within and outside the colony, hatched out and identified. No

larvæ were found in the colony from April to June and in November and December.

Identification.—There were 13 varieties of anopheline found from adult catches and ten from hatched-out ones. Five of them were dangerous, three of doubtful nature and the rest non-carriers. The highest incidence is of *A. culicifacies* and next comes *A. rossi*.

Anopheline fauna of Barwadih

Dangerous type	Doubtful type	Non-carriers
1. <i>A. culicifacies</i> .	1. <i>A. annularis</i> .	1. <i>A. rossi</i> .
2. <i>A. funestus</i> .	2. <i>A. maculipalpis</i> .	2. <i>A. vagus</i> .
3. <i>A. stephensi</i> .	3. <i>A. pallidus</i> .	3. <i>A. theobaldi</i> .
4. <i>A. maculatus</i> .		4. <i>A. hyrcanus</i> .
5. <i>A. listoni</i> .		5. <i>A. jeyporiensis</i> .

The monthly incidence of the local carrier is illustrated in the accompanying graph :—

Monthly incidence of *A. culicifacies* (local carrier) —
Monthly incidence of *A. rossi* - - - - -

Anopheline fauna of Barwadih

Sun-breeders.—The possibility of the existence of sun-breeders such as *A. maculatus*, *A. listoni* or *A. minimus* in a montane or submontane region is very great. Deforestation in such regions has been known to have caused a severe epidemic of malaria in an otherwise endemic area. They breed in open spaces against which jungle and shade are the best remedies. Hill rivers, such as we have on the north, which swell during rains leaving pools of water in their beds, hill streams and springs among rocks, as we have at the foot of the hill on the south, and collections of water which have no marginal vegetation are all potential sources of *A. maculatus*. We were alive to the danger and took precautions to guard against it till in 1935 we caught *A. maculatus*. An extensive search was made and we hatched out a few larvæ and thus detected breeding places in the colony and outside and adequately dealt with them.

Dissection.—We dissected dangerous and doubtful varieties and when time permitted a few non-carriers as well. In 1935 after dissecting 5,355 mosquitoes we found sporozoites in *A. culicifacies* from the morning catch within the colony on 26th August, 1935. A month later another *A. culicifacies* from an evening catch from the Karia bustee outside the colony was found positive. The total number dissected was 20,138 out of which only two *A. culicifacies* were found positive in 1935 and none in 1936.

Parasitic index.—This was recorded twice a year in March and September through examination of the blood of almost all the healthy persons in the colony. A monthly record of all the cases examined was also kept.

Splenic index.—Separate records of the enlargement of the spleen in children below 10 and of persons above 10 years of age were kept. The splenic index given in this paper is of children below 10 years.

Blood slides of patients.—The blood of all the fever cases was examined. The blood of positive cases was taken every day to note the effect of the remedies on the disappearance of parasites from the blood. The blood was also examined at the end of quinine or atabrin treatment to see if gametocytes persisted and whether a course of plasmochin was indicated or not.

Clinical control.—Man is a reservoir of malaria. Mosquitoes are only carriers. The treatment of infected cases is therefore as important as the destruction of mosquitoes. We have very comfortable indoor accommodation to treat malaria cases in the hospital and have an efficient organization immediately to detect, diagnose and treat the cases occurring anywhere in the colony.

We tried various modes and combinations for administering quinine, atabrin and plasmochin and tonics in an attempt to cut down the actual sick days and recuperation time, and achieved great success. We reduced the days of fever from 10 to 5 and then to 3 and recuperation time from 7.5 to 4.5 days. The question of carriers from amongst the sick was dealt with by examining their blood and if gametocytes were found by giving a course of plasmochin.

Results

(1) We found the local carrier *A. culicifacies* by actual dissection.

(2) We found the sun-breeder *A. maculatus*.

(3) We reduced the number of sick days due to malaria as well as to all other diseases. The parasitic index dropped from 26.5 in 1933 to 0.7 in 1935; splenic index from 26 to 6, total malaria sickness from 231.5 to 99.5 per mille and sick days lost due to malaria from 3,059 to 1,179.

(4) The table below gives all the figures from 1930 to 1936 including the cost of all the operations except the engineering work :—

TABLE
Showing the results obtained by anti-malaria work at Barwadih

Particulars	1930	1931	1932	1933	1934	1935	1936

Note.—The figures given are for the employees only as the figures for families are variable and cannot be relied upon for accurate comparison.

TABLE
Showing comparative figures of malaria sickness at district board and railway hospital at Barwadih

Particulars	1930	1931	1932	1933	1934	1935	1936
District board dispensary	564	573	511	457	711	710	829
Railway colony ..	585	311	346	185	130	103	101

Just outside our colony is a district board dispensary. Cases from neighbouring villages are treated at this dispensary. The figures of malaria and all other diseases treated there year to year as compared to ours are illuminating. Their figures remain practically constant, inclining, if at all, to an increase while we reduced our malaria incidence by 84 per cent and total sickness by 54 per cent in 5 years.

I am much indebted to Dr. F. E. R. Laborda, Chief Medical Officer, E. B. Railway, for his valuable help in the preparation of this paper. I also wish to show my appreciation for the excellent records kept by my colleague Dr. J. R. Bhatia, Divisional Medical Officer in charge, Barwadih, from 1931 to 1934. My thanks are due to Dr. S. C. Chatterjee, Chief Medical Officer, E. I. Railway, for his permission to publish this report.

A CASE OF MONILIASIS WITH A SECONDARY ALLERGIC PATCH OR 'MONILIIDE'

By L. M. GHOSH, M.B., D.T.M.

(From the Medical Mycology Inquiry, Calcutta School of Tropical Medicine under the Indian Research Fund Association)

A HINDU aged 20 years had suffered from extensive ulceration of the vulva and vagina for the last eight years. She had had various unspecified treatments by different doctors with periodical improvement and remission but was never cured. Two years ago she had a child and since then the disease has become much worse. She was of average build but looked miserable and ill on account of her suffering.

Besides the vulvo-vaginitis there were lesions between the toes and a depigmented patch of exfoliation on the back of the right arm.

Lesions

Both the labia majora were studded with ulcers of varying size. The labia minora also were affected but not so severely; there were only a few small ulcers on them (figure 1). The vagina was also affected. The anterior portion of the vagina had many small ulcers and healed scars and there was a white creamy discharge. The ulcers were mostly small with a red areola surrounding each one, the margins were sharp and the surface was covered with a white creamy membrane,

Fig 1.—Ulcers on the vulva

Fig 2.—Allergic patch on the arm; 'monilide'.

Fig 3.—Interdigital lesions of the feet.

underneath which were unhealthy granulations. They were painful and had a whitish discharge. Some of the ulcers on the labia majora were the size of a

four-anna piece or larger, the result of the coalescence of several small adjacent ones. On the left side of the perineum there was a large ulcer. The interdigital spaces in both feet between the third and the fourth toes were affected and the area was covered with white scaling sodden epidermis. This had the appearance typical of 'mangoe toe' (figure 3).

On the back of the right upper arm there was a tightly-scaling depigmented patch about 4 inches by 2 inches. This patch gave no subjective symptoms (figure 2).

Pathological examination

Serapings from the arm showed only slight parakeratosis in the scales and no fungus could be found.

Culture from the same patch on the arm showed no fungus but growth of staphylococci and spore-forming bacteria.

Serapings from the interdigital spaces showed a few yeast-like bodies, common cocci and bacteria.

Smears from the ulcers on the vulva showed numerous gram-positive and gram-negative cocci, bacteria and a few yeast-like bodies.

Culture.—From the feet and from the ulcers in the vulva, staphylococci, gram-negative short bacilli and many small white creamy colonies looking like monilia were isolated and the latter when examined under the microscope showed mycelial threads and budding yeast-like bodies. Two of these colonies were picked up and subcultures made; they were marked A and B. The organisms showed the typical morphology of a monilia having mycelial and budding forms. They were then put through various sugars, peptone water, broth, and litmus-milk, to determine the species.

Four sets of cultures were done in the first series and in all the four the biochemical properties of the colonies A and B were different in that colony B, besides producing acid and gas in the same sugars as colony A, produced in addition acid in lactose, salicin, sorbitol, mannitol and decolorized litmus-milk. The reactions were so constant in all the four experiments that at first it was thought that there were two species of monilia from the same case, colony B being a new species hitherto unreported. To make certain, 24-hour subcultures of both the colonies in a glucose solution were plated out in McConkey's bile-salt lactose agar medium. In plate A all the colonies appeared to be the same and two of these were picked up. But in plate B two types of colonies appeared and two colonies from each type were picked up and subcultures made. The subculture from A and B when stained showed that both the colonies from A were monilia while of the colonies from B two were found to be monilia and the other two were staphylococci. The four subcultures of monilia, two from A and two from B, were again tested for their biochemical properties (table II) and this time they were found to be identical.

In determining the species of monilia Castellani has utilized their properties of producing acid and gas in different sugars as determining factors. Later authors in following him have

TABLE
Two cultures of monilia from the same case—Colony A and Colony B

Dextrose	Levulose	Maltose	Galactose	Saccharose	Lactose	Mannitol	Dulcitol	Dextrin	Raffinose	Arabinose	Adonitol	Inulin	Sorbitol	Mannose	Peptone water	Inositol	Salicin	Broth	Litmus-milk	Colour of growth on dextrose agar
----------	----------	---------	-----------	------------	---------	----------	----------	---------	-----------	-----------	----------	--------	----------	---------	---------------	----------	---------	-------	-------------	-----------------------------------

TABLE I—FIRST SERIES

Four experiments were done and the results were practically the same in all.

A..	AG	AG	AG	AG	AG	O	O	O	AS	O	O	O	O	O	AG	Not done	O	O	Not done	O	White creamy.
B..	AG	AG	AG	A/G	AG	A	A	O	AS	O	O	O	O	A	AG	"	O	A	"	D	White creamy.

TABLE II—SECOND SERIES AFTER PLATING

Four experiments were done and the results were identical.

Monilia paratropicalis, Castellani, 1909.

A..	AG	AG	AG	AG	AG	AS	AG	C	CTS	O	White creamy.
B..	AG	AG	AG	AG	AG	AS	AG	C	CTS	O	White creamy.

N.B.—A = Acid.

AG = Acid and gas

AS = Acid slightly.

A/G = Sometimes acid and gas and sometimes acid only.

C = Clot in milk and clear in peptone water and broth

CTS = At first clear afterwards slightly turbid.

D = Litmus-milk decolorized.

O = Negative.

All readings were taken up to 7 days.

taken the production of gas with acid as the determining factor and have not taken into consideration the production of acid only without gas—this phenomenon being in their opinion not a constant factor. While I am not in favour of recognizing plurality of species, the production of acid being constant in all the eight experiments this phenomenon cannot be neglected and hence it is considered that this species, is *Monilia paratropicalis*, Castellani 1909 as it produced acid in dextrin which differentiates it from *Monilia tropicalis*.

Discussion of case.—The lesions in the perineal region and the feet were clinically moniliasis; this diagnosis was confirmed by micros-

copic and cultural findings. The patch on the back of the arm was negative for fungi but it improved along with the improvement of the lesions in the other parts, hence I feel justified in considering this patch an allergic lesion, moniliide, allied to those produced by trichophyta and certain bacteria.

Progress.—The patient was ordered to wash the lesions with lysol solution (15 drops to a pint of hot water) twice daily and then to paint with a solution containing gentian violet—5 grains, brilliant green—5 grains, rectified spirit—1 drachm and water to 1 ounce. The lesions responded quickly to the treatment and were quite cured within a month.

A Mirror of Hospital Practice

AN UNUSUAL CASE OF SUBTERTIAN MALARIA

By SUDHIR CHANDRA ROY, B.Sc., M.B., D.T.M.
Kurigram, Rangpur

THE patient was a male aged 28 years.

History.—On rising one morning he could not speak although he could understand what was said. From about 8 a.m. that day, the temperature gradually began to rise and reached 105.8°F. at 4 p.m. when I saw the patient.

On examination it was found that the spleen was enlarged one inch below the costal margin, tongue

slightly coated, pulse very feeble, 150 per minute, regular; bowels constipated.

Immediate blood examination not being possible one blood slide was taken and as malaria was suspected quinine bihydrochloride gr. x was injected intramuscularly. An alkaline diuretic mixture and also a quinine mixture were prescribed.

The blood slide revealed a large number of subtertian rings in every field.

The temperature of the patient next day was 101°F. but there was paralysis of the right lower extremity and marked paresis of the right upper extremity; other conditions about the same as on previous day. Another injection of quinine bihydrochloride, gr. x, was given intramuscularly and mixtures continued.

The next day the condition of the patient grew worse and he began to pass a copious amount of bright-red blood from the bowel. He passed four or five such motions that day. The temperature was 100°F. Another injection of quinine bihydrochloride gr. x was given intramuscularly and four doses of kaolin 3ii of powder were given.

Next day the temperature came down to normal, blood in stool disappeared and pulse condition improved. The patient then gradually recovered.

I had the opportunity of seeing this patient again 4 months after this attack when I found that the paralysis and aphasia were completely cured.

Points of interest in the case :—

Although quinine was given in sufficient amount (gr. 25 daily) from the first day of illness several unusual symptoms made their appearances one after another. These were :—

- (a) Aphasia followed by hyperpyrexia on the first day.
- (b) Paralysis of right lower extremity and marked paresis of right upper extremity on the second day.
- (c) Severe hæmorrhage from bowels on the third day.

PURULENT ARTHRITIS COMPLICATING SMALLPOX

By E. H. WALLACE

CAPTAIN, I.M.S.

Civil Surgeon, Malakand

and

AMIN-UL-HUQ, M.B., D.S.

In-Charge, Lady Minto Hospital, Malakand

THE following five cases are described as it is thought that textbooks do not dwell in sufficient detail upon this deforming complication of a disease so common in India. They were collected from a district where smallpox is endemic and vaccination is not a common practice.

Case 1.—*Act.* 9 years. Discrete modified smallpox one month previously, pox present; ambulatory treatment. Destructive purulent arthritis of both acromio-clavicular joints with continued fever, pain and swelling. Treated by incision into joints which were eroded, glove drain—healed in 29 days. Secondary abscesses formed after one week on anterior part of tibia and vertebral border of scapula, under the periosteum, treated by incision with healing in three weeks. Bi-weekly mercurochrome 10 c.cm. of 1 in 500 intravenously to control pyæmia.

Case 2.—*Act.* 8 years. Discrete modified smallpox two months ago, followed by fever and swelling of both elbow joints. One joint incised by a local barber with consequent total destruction, necrosed ulna apparent in depths of sloughing wound. Arthrectomy of right elbow joint followed immediately by hyper-flexion in plaster of paris. Left elbow put into plaster at most acute angle possible. Right elbow healed by granulation forming fixed ankylosed joint in five weeks. Swelling of left elbow gradually subsided leaving a joint capable of good limited movement. Prontosil and 10 c.cm. of 1 in 200 acriflavine intravenously as adjuvant treatment.

Case 3.—*Act.* 9 years. Modified smallpox six weeks previously. Abscess involvement of right elbow and knee joints. Put into plaster in hyper-flexion and extension respectively immediately. On 11th day right acromio-clavicular joint became swollen and painful

and finally pus was aspirated, incision and drainage was necessary. Left parotitis developed on 23rd day and subsided within five days. Discharged with limited movements of elbow and knee joints after six weeks. Adjuvant treatment with sulphonilamide (Bayer), intravenous mercurochrome and acriflavine.

Case 4.—*Act.* 3 years. Severe discrete smallpox two months ago, blindness of both eyes due to keratitis. Purulent arthritis of right elbow, abscess had burst exposing lower end of humerus posteriorly. Radical arthrectomy required to remove necrosed bone; joint placed in plaster in hyper-flexion immediately, giving an ankylosed joint in six weeks. Following operation there were peri-articular abscesses of both hip and knee and right ankle joints—these were incised and drained and the limbs put into posterior plaster splints; these healed in three weeks giving movable joints.

Case 5.—*Act.* 5 years. Mild smallpox three months ago. Two months after attack right elbow commenced to swell and the abscess burst laterally after three weeks through a double posterior sinus through which the joint could be entered. Radical arthrectomy followed by immediate hyper-flexion in plaster. Healed by granulation in seven weeks, giving a satisfactory arthrodesis.

Summary

1. The actual attacks of smallpox, all occurring in unprotected children under 10 years of age, were mild and discrete, never confluent or hæmorrhagic.

2. Joint complications appeared in 4 to 8 weeks of convalescence and took the form of an initial peri-articular abscess which burst first into the joint and then through the skin.

3. Initial treatment was ambulatory.

4. In treatment one notes the value of immediate immobilization in plaster either following arthrectomy, or before the abscess bursts into the joint in the early stage.

5. Prontosil, mercurochrome or acriflavine intravenously appeared to have no influence on treatment.

A CASE OF GNATHOSTOMIASIS WITH SOME INTERESTING FEATURES

By P. A. MAPLESTONE, D.S.O., D.S.C., M.B., B.S., D.T.M.

and

S. SUNDAR RAO, L.M.P.

(From the Helminthological Research Laboratory, School of Tropical Medicine, Calcutta)

THE first instance of a gnathostome infection of a human being in India was reported by Maplestone (1929), and since that time the same worker has recorded three more.

The same man, in whom the first recorded infection occurred, came recently with a similar condition again. Before discussing the history of the present manifestation it is thought advisable to recapitulate briefly the main points in the first infection.

He is a Mahomedan clerk who was at that time 26 years of age. He had lived in the Jalpaiguri district of Bengal for many years prior to the attack and had never been out of the province in his life. For a period of about seven years he had suffered with transient swellings in various parts of the right hand, which in the

final attack was localized in the middle finger. The man noticed a small whitish point beside the nail and when this was opened with a needle a small worm escaped. This worm was identified as a gnathostome and described by Maplestone (*loc. cit.*). After the worm had been removed the swelling of the hand ceased altogether. The patient was not seen by us on this occasion, but the case notes and the worm were forwarded by the civil surgeon, Jalpaiguri.

In the intervening ten years this man has remained all the time in the same district, and he recently reported at the out-patient department of the School of Tropical Medicine, Calcutta.

He gave the following history :—

In 1930, about a year after the first worm was removed and all attacks of swelling of the right hand had ceased, he noticed an oedematous swelling on the left side of the chest, just above and inside the nipple. This swelling soon subsided and shortly afterwards another one appeared over the sternum, which remained until 1936. It then disappeared and in 1937 a third swelling appeared on the right side of the chest. During 1938 transient swellings occurred in various parts of the right arm, finally reaching a position just above the right wrist. At the beginning of May this year (1939) the right forearm became swollen and subsided in about a week. On 29th May the right middle finger swelled, and he came to Calcutta where he was seen by us on 2nd June. He had a blister on the pulp of the finger. This was incised and a small worm together with a few drops of serum escaped.

The worm was found to be not unlike the one removed from the same patient ten years earlier. This specimen was better fixed than the previous one so that there was no shrinkage, which fact may account for its slightly larger size, but apart from this the stage of development was no further advanced and there were the same number of rows of spines (four) on the head bulb.

	Old specimen	New specimen
Length ..	3.56	5.28
Maximum diameter ..	0.42	0.54
Diameter of head bulb ..	0.34	0.33
Length of head bulb ..	0.20	0.22

(Measurements in millimetres.)

This case presents several interesting features, which are discussed below.

The infection seems to have persisted much longer than has ever been recorded before. Although it cannot be proved it appears probable that infection with both worms was acquired at the same time, because the disease is such a rarity in India the chances of the same man being infected on two different occasions appears very remote. If this is accepted it gives a minimum of 17 years that these worms have lived in the body of the man.

The worms do not appear to have undergone any development over this long period as the two worms, removed with an interval of ten years between, are in the same stage of immaturity. This is all the more interesting because some gnathostomes that have been removed from human beings have shown sufficiently advanced development to have been classed as

adults. Therefore there must be factors other than of time which determine the development of these worms in the human tissues.

It is a remarkable coincidence that both worms finally reached the surface near the tip of the same finger after extensive migration through the body.

The man said that on very rare occasions he has eaten uncooked dried fish which may account for his infection.

'PRONTOSIL ALBUM' IN ILIAC ABSCESS

By S. B. SEN GUPTA, L.M.F.

and

M. ALI, L.M.F.

Berch Tea Estate, Hasimara, Jalpaiguri

T. D., aged about 6, a female child, was brought by her father. She complained of pain in the left iliac region for the last eight days during walking and could not extend her leg fully and was not able to stand on that side. She also had irregular daily rise of temperature. She developed this after she had one small boil on her left buttock which gave her trouble for about seven days. On examination of the part an abscess was found in the left iliac fossa. We advised absolute rest in bed. We gave her 'Prontosil album', 1 tablet 4 times a day, and alkaline mixture with potassium iodide t.d.s. for 10 days. Antiphlogistine was applied locally. During the course of treatment she showed remarkable improvement in all respects and at the end of the third week of treatment she was completely recovered.

We are indebted to Dr. W. G. Cattell, for his kind permission to publish this note.

NEGLECTED COMPOUND FRACTURE OF THE TIBIA

By D. N. KARMOKAR, L.M.F.

Assistant Medical Officer, Rajmai Tea Estate, Upper Assam

A TEA-GARDEN coolie boy, aged about 9 years, while staying in a distant bungalow with one of his relations, fell from a mango tree about 8 months ago and got a compound fracture of the left tibia.

In the latter part of April, he was brought home by his parents and on the 1st May he came to the hospital on foot for treatment.

The affected leg was found to be slightly curved, with a fairly clean wound on the anterior surface, through which the upper part of the lower fragment of the left tibia protruded for about an inch and on further examination this fragment, which was about 3½ inches long, was found to be loose. This was subsequently pulled out without any difficulty, leaving a sinus about 3 inches in depth. As the parents refused any operative measures on the child, the sinus was dressed with iodoform gauze and it healed up within four weeks.

It is remarkable that the boy had a compound fracture of the tibia and without treatment he got no generalized sepsis or tetanus and could follow his ordinary daily pursuits without difficulty.

Acknowledgment

My thanks are due to my chief Dr. J. C. Paisley for his valuable advice in the management of the case.

ASEPSIS IN THE OPERATING THEATRE

It is a good thing to have our complacency disturbed from time to time. Recent investigations on asepsis in the operating theatre will give surgeons considerable food for thought and lead, we hope, to some close questioning on the routine methods of sterilization of dressings and instruments in their own hospitals. Most surgeons have had experience of a temporary break-down in the asepsis of their theatres, evidenced by a series of wound infections after 'clean' operations. A general tightening up of the theatre management has usually ended these incidents, and, whilst some unfortunate person has received the blame for an actual or supposed, but often minor, lapse from aseptic or antiseptic ritual, the real cause of the trouble has seldom been ascertained.

Some years ago doubt entered the mind of Col. Hayes of the Lady Willingdon Hospital, Lahore, as to the efficiency of the usual methods adopted for the sterilization of dressings, towels, etc. He first reviewed his own knowledge on the subject and found it was rather vague; he questioned his colleagues and found that their knowledge was equally sketchy. He then investigated more closely the sterilizing procedures at his own, presumably, and at other similar institutions, and found, that, whilst all the surgeons were satisfied that the sterilization was carried out properly, few had any knowledge of the details, that the sterilizing procedure was not usually supervised by a responsible person and seldom by a sister, that the packing of the drums was left to young and inexperienced probationers, that the procedure for operating the steam sterilizer was governed by the manufacturers' instructions, and that even these were sometimes misunderstood.

Accepting 115°C. for twenty minutes, which will kill tetanus spores, as the ideal to be achieved, he estimated by means of a thermometer which he placed inside the drums the time interval, in various circumstances, before this temperature was reached; he found that in many circumstances the temperature of 115°C. was not even achieved during the sterilization procedure laid down by the manufacturers of the sterilizers used, and that in every instance there was a time lag which had not been sufficiently allowed for in the manufacturers' instructions, so that when these are followed this temperature (115°C.), even if it is ever reached, is not maintained for a long enough period (*B. M. J.*, 1937, i, 911).

The fact that you cannot accept the pressure gauge as a substitute for a thermometer was

further emphasized by Rishworth who has pointed out that the correlation tables between pressure and temperature usually employed are based on experiments with pure steam, but that, as in practice there is very incomplete exhaustion of air, these correlation tables cannot be applied. He reproduced from Underwood's *Textbook of Sterilization* two most instructive charts, one showing the extremely low temperature reached, even after 70 minutes, when no air has been discharged or when air has only been partially exhausted, and the second showing the differences in the temperature in various parts of the sterilizer; from the latter it can be seen that, when the pressure gauge has been recording, inferentially, a temperature of 250°F. for as long as twenty minutes, in the presence of air, the temperature in the lower part of the sterilizer has only reached a nice fever heat in which most micro-organisms would thrive. The morals he gathers from this are that there should be some means of reading the actual temperature inside a packed dressing drum near the bottom of the sterilizer and that the air outlet should be at the bottom, and not at the top as it is in many types of sterilizer (*B. M. J.*, 1938, ii, 974).

These two papers read in conjunction with Pulvertaft's (*B. M. J.*, 1937, i, 441) bacteriological study of 'sterile' accouchement sets (put up by well-known and reputable firms) from a very high percentage of which he was able to recover *Clostridium welchii*, *Cl. tetani* and *Cl. sporogenes* should shake the faith of surgeons and gynaecologists who have in the past accepted unquestioningly the unopened drum and the packed 'sterile' dressing. But these are not the only source of sepsis in the operating theatre. In a recent paper in the *Lancet* (1939, i, 1088) Devenish and Miles have reported an investigation to discover the cause of a series of *Staphylococcus aureus* infections of 'clean' operation wounds in a London hospital. The source of the infection in this instance was the surgeon's hands, through punctures in his rubber gloves. Of two surgeons operating in the same theatre, one did 141 'clean' operations of which 20 suppurated and the other did 84 of which one suppurated: the former was a 'skin carrier' of *Staph. aureus*. In normal circumstances punctures in gloves were found in 24 per cent of instances and after very careful precautions this percentage was reduced to 14. In these improved circumstances, though a rich culture of *Staph. aureus* could still be obtained from inside his gloves at the end of an operation, the former surgeon performed a series of 35 clean operations without any suppuration occurring, which suggests that the leakage of staphylococci in sufficient dosage to cause an infection does not always occur, even when holes are present in the gloves, and other routes were suggested.

Now, to complete the surgeon's discomfort, Brewer (*J. A. M. A.*, 112, 2009) has shown that

the claims made regarding the sterilizing powers of certain well-known mercurials are dependent upon unsound methods of bacteriological investigation. He found that in a series of 120 surgical operations the cutting instruments

revealed 12 per cent contamination with spore-forming anaerobes, and that eight per cent of the knives used for making the skin incisions were contaminated with *Clostridium welchii* or similar organisms.

Special Article

LEPROSY AND TUBERCULOSIS

A lecture delivered to the post-graduate course in tuberculosis organized by the King George Thanksgiving (Anti-tuberculosis) Fund, Calcutta, February 1939.

By J. LOWE, M.D.

Research Worker under British Empire Leprosy Relief Association, Indian Council, and Officer-in-charge, Leprosy Research Department, School of Tropical Medicine, Calcutta

I ATTEMPT in this lecture to discuss some of the ways in which these two diseases resemble each other or else differ from each other.

Ætiology

Both these diseases are caused by organisms which are classified under the group 'mycobacterium'. It might be interesting for a moment to go back to the early days of bacteriology and remind ourselves how these two bacilli were discovered. In the seventeenth century, Kircher had stated in a primitive way the theory of contagion and infectious disease. A little later van Leeuwenhoek had seen bacteria, bacilli and spirilla in smears taken from the teeth, but he did not connect such bodies with disease. It was nearly a century later that von Plenciz advanced the idea that minute bodies might convey diseases from person to person and that each infectious disease had its own causative agent, but he did not state what these agents could be. Nearly three-quarters of a century later still, these early theories began to bear fruit. In 1836 Schwann showed that putrefaction was caused by a living body which could be destroyed by heat. About the same time the nature of yeasts was discovered. In 1840 Henle surmised that disease was spread by living infective bodies. In 1846 Klenche showed that tuberculosis could be transmitted in some unknown way by cows' milk, and twenty years later Villeman showed that tuberculosis was caused by an invisible living agent which was transmissible. In the same year, 1865, Davaine discovered the bacillus of anthrax in sheep. In 1870, bacteriology was in its early infancy. Few people believed that bacteria had anything to do with disease. Diseases were attributed to all kinds of other causes and no bacteria pathogenic to man had been seen or described.

In 1870, a young man, Armaur Hansen, was studying leprosy in Norway. He concluded that leprosy was infectious and was probably caused

by a micro-organism, and he was searching in microscope preparations made from leprosy lesions for the causative organism of the disease. He had poor microscopes compared with our modern instruments, and he had no aniline dyes with which to stain the bacilli. He stained the specimens with osmic acid and he saw bodies which he thought must be the organism of leprosy. This was the first organism to be reported as occurring in the tissues of man. This was one of the great landmarks of medicine and an achievement for which full credit has not been given to Hansen. Hansen published his results in 1873 and practically no one believed him. His preparations were not good enough to convince the sceptics.

In the same year, 1873, a young doctor, Robert Koch, was working in a country practice in Germany after serving in the Franco-Prussian war. In his spare time he studied the bacillus of anthrax which had been discovered in sheep 8 years before. He observed and described the different forms of this organism and its development. A few years later, while still doing country practice, he studied the staining of bacilli by aniline dyes which had recently been used in histology, and found that bacteria stained very well with these dyes.

Later, Hansen adopted Koch's method of staining bacilli and was able to make preparations of the leprosy bacillus so good that the sceptics were convinced and Hansen's bacillus assumed its proper place as the cause of leprosy.

A few years later Robert Koch, now an officer of the Imperial Health Department of Germany with a laboratory and staff at his disposal, turned his attention to tuberculosis and was able to demonstrate a bacillus practically identical with Hansen's bacillus.

Thus, in the early days of bacteriology leprosy research and tuberculosis research helped each other and so we hope will continue to help each other. Koch cultured the organism of tuberculosis and infected experimental animals and thus opened a vast field for research. The leprosy bacillus which was discovered first was soon left far behind and the bacillus even to-day has probably not been cultivated and no experimental animal has been infected. All attempts to apply to the organism of leprosy the refinements of cultural technique which have been worked out so thoroughly in tuberculosis have so far failed.

Immunology

As the result of developments in bacteriology there have been developments in knowledge of immunology of these two diseases. In tuberculosis we have various forms of the tuberculin test the most useful of which is the Mantoux test. It is interesting to note that in leprosy we have rather a similar test, the leprolin test. Leprolin is prepared not from cultures, because we have none, but from leprous lesions themselves. There are certain important differences between the leprolin test and the tuberculin test, but I cannot discuss these now.

In tuberculosis much work has been done in recent years on complement fixation and similar work has also been done in leprosy. For complement fixation in leprosy we find that the best available antigen at the present moment is what is known as the WKK antigen which is prepared from tubercle bacilli, and there is considerable evidence to show that the immunological reactions of these two diseases have very much in common and that the two bacilli are antigenically related.

Transmission

In transmission, however, we find that there are considerable differences between the two diseases as well as certain similarities. Let us deal with the differences first.

Tuberculosis is transmitted either by inhalation or by ingestion of tubercle bacilli. There is however no proof that leprosy can be transmitted by either of these methods, and it seems most likely that it is transmitted by inoculation of bacilli into broken skin or mucous membrane.

Let us consider resemblances in transmission. Leprosy and tuberculosis are both very often diseases of families, and in both diseases, in the past the possibility of intra-uterine transmission has been discussed. In leprosy it has been shown that a leprous woman whose tissues may teem with lepra bacilli can become pregnant and bear a child, and that lepra bacilli may be numerous in the placenta, may be found in the umbilical cord, and even occasionally in the tissues of the new-born child, but that, if the child is separated from the mother at birth, it does not develop leprosy. I believe that similar findings have been made in tuberculosis and it appears that neither of these two diseases can be transmitted *in utero*.

Another point in which the transmission of the two diseases is similar is in the case with which they are transmitted to children and young people and the relative difficulty with which they are transmitted to adults. This is a matter about which I shall say more later.

Clinical and pathological findings

Clinically, there are of course very marked differences between leprosy and tuberculosis. Tuberculosis affects the internal organs very much more than leprosy, which affects chiefly the skin, nerves, and mucous membranes.

Leprosy does affect some of the internal organs but only to a relatively mild degree. It is, however, interesting to note that the two internal organs most commonly affected in tuberculosis, namely, the lung and the intestinal tract, are rarely if ever affected in leprosy.

It is in the skin that leprosy may produce lesions very much like the lesions of skin tuberculosis or the tuberculide. These leprous lesions in the skin resemble so closely the skin lesions of tuberculosis that they have been called tuberculoid leprosy, or leprides. There are, however, certain clinical differences, the most important being that in the leprous lesions of this variety there is impairment of skin sensation and often thickening of cutaneous nerves supplying the patch. This nerve thickening may extend up to the nerve trunk. When you get a case of suspected tuberculide you should consider whether it may not be due to leprosy. Test the sensation of the skin of the patch and examine for thickening of nerves.

When leprous lesions of this variety were first described, some workers refused to believe that they were due to leprosy and thought that they were tuberculous lesions occurring in a leper. Now, it is generally accepted that they are due to leprosy. In some countries they are apparently much more commonly seen than in other countries, in India they are very common indeed.

Another way in which the clinical aspects of these two diseases show some resemblance is in the occurrence in both diseases of allergic reactions with a temporary increase in the signs and symptoms.

You will have heard about allergic reactions in tuberculosis and their significance, how they may produce a temporary increase in the clinical signs, and how the occurrence of these reactions is not necessarily a bad sign for in some cases (but perhaps not in all), allergy goes hand in hand with immunity, and allergic reaction may be followed by quiescence and arrest of the disease. Similar reactions are also seen in leprosy and they may produce alarming symptoms which, however, always subside in time without any special treatment. These reactions are not infrequently followed by long inactivity and sometimes by arrest of the disease. The failure to recognize allergic reactions in both leprosy and tuberculosis, and the failure to attribute to these reactions their proper significance, is one of the commonest causes of errors of clinical judgment in dealing with these two diseases.

Another way in which the two diseases resemble each other is by the occurrence in both of them of cold abscess. Tuberculous cold abscess and its features are well known to every one, but not many clinicians know that leprosy may cause cold abscess.

It is in the type of leprosy which has been called tuberculoid that cold abscess is sometimes seen. It occurs in nerves, sometimes in the cutaneous nerves supplying tuberculoid lesions

in the skin, and sometimes in nerve trunks. In cutaneous nerves it occurs in the form of small round or oval swellings which may be multiple. In nerve trunks it occurs first in the form of a fusiform swelling usually single, but as the process of caseation progresses the cold abscess may burst through the nerve sheath and form round or oval encapsulated swellings alongside a nerve which may attain the size of a hen's egg, or may track quite a long distance down a limb. Such abscesses sometimes discharge through the skin.

While I am discussing the clinical aspects of the two diseases I might emphasize the fact that leprosy itself rarely causes death, and that particularly in leprosy institutions, one of the commonest causes of death is tuberculosis of the lungs. Thus, you may have leprosy and tuberculosis in the same patient and this may cause a little difficulty in correct diagnosis. It should be remembered that in advanced cases of leprosy, lepra bacilli may be found in the sputum and in the faeces. They usually come not from the lungs but from the mucous membranes of the larynx, pharynx and the trachea. Thus, acid-fast bacilli in the secretions and excretions of a leper may be lepra bacilli or they may be tubercle bacilli. It is impossible to differentiate one from the other merely from the appearance of the individual bacillus, but the fact that lepra bacilli are usually more numerous and occur in masses may be of assistance. Also it is to be remembered that in such cases definite signs in the lung are usually caused by tuberculosis, for leprosy rarely if ever affects the lung.

In some cases, however, guinea-pig inoculation of bacilli is necessary for accurate diagnosis, the guinea-pig not being susceptible to the leprosy bacillus.

Epidemiology and Control

I will now discuss certain points in the epidemiology of these two diseases. Some striking resemblances and some marked differences will be seen. Modern thought has emphasized the idea that all diseases tend to occur in epidemics. They are introduced into a community; they spread to begin with usually in a relatively severe form; the incidence rises to a peak and then declines, the diseases appearing in a mild form, and finally the epidemics die out, though further epidemics may occur later. The factors causing this decline of epidemics are very uncertain.

The acute diseases have short epidemic periods, perhaps only a few weeks or months, e.g., cholera, plague. The more chronic diseases have longer epidemic periods. It is suggested that tuberculosis, a chronic disease, has a very long epidemic period, possibly two or three hundred years or more from start to finish. What evidence is there to support this view of the epidemic nature of tuberculosis?

A study of tuberculosis in western Europe gives us the following ideas:—

(a) Tuberculosis has been declining in western Europe for many years. The mortality rate in England and Scotland has fallen 75 per cent in the last 50 years.

(b) It appears almost certain that the decline started long before the infectious nature and mode of transmission of the disease were generally realized, long before the bacillus was discovered, and long before any anti-tuberculosis work started. The decline started and continued during the period of rapid industrialization which would seem to favour the spread of tuberculosis.

(c) Although anti-tuberculosis work has not caused the decline, it has probably accelerated it markedly, and it is noteworthy that the temporary deterioration in environmental conditions and the temporary hold up of preventive work which occurred during the European war was accompanied by a temporary increase in the tuberculosis rate. This is a strong indication of the value of hygiene and anti-tuberculosis work, but the decline is due largely to other factors, some of which are beyond control.

The following factors have been suggested as tending to produce a decline in the tuberculosis incidence:—

(1) Increase in racial resistance caused by the elimination by death of susceptible stock, (2) the fall in the birth rate and the increased length of life with marked changes in the age distribution of the population, children forming a very much smaller proportion of the population than in the past. The morbidity and mortality rate of tuberculosis is always highest in young people but if the young people in the population are few, the tuberculosis rate falls correspondingly. (3) Marked improvement in social and hygienic conditions, nutrition, housing, etc.

These ideas have frequently been expressed about tuberculosis in western Europe. I now want to ask the question, 'Does leprosy occur in epidemics which decline spontaneously as the result of factors largely beyond control'?

There is undoubtedly some evidence that it does. When we study the history of leprosy we find that Europe experienced an epidemic which lasted in all for over 1,000 years. In the thirteenth century, leprosy was probably about as common in England as it is in India to-day, but 400 years later it had almost disappeared. All kinds of reasons have been given for this strange phenomenon, but none of them is satisfactory and it seems probable that it was the natural decline of an epidemic possibly accelerated by segregation of lepers and by improved social and hygienic conditions and nutrition. Now let us consider India. Are these diseases occurring in the form of long-period epidemics and if so at what phase of the epidemic are we at present?

When considering this question it should first be stated that the same disease may occur in

different forms in different parts of the world. In some places, plague, for example, appears in epidemic form and then disappears entirely, while in other places it is persistently endemic. The same may possibly be true of leprosy and tuberculosis; they may be epidemic in some parts and persistently endemic in other parts. What can cause these differences is not clear.

There are, however, some indications that these two diseases are occurring in India in the form of long-period epidemics, and there are certain things which suggest that the epidemic of leprosy may be past its height, while the epidemic of tuberculosis may be now on the up grade. The available evidence is based on information concerning the incidence and severity of the two diseases.

Let us first consider leprosy. Statistics in India are very inadequate and unreliable, but such as they are, they do not suggest that the incidence of leprosy is increasing in India as a whole. The number of lepers reported in India in the census of 1871 was about the same as was reported in 1921 in spite of the very large increase in population during this period. (Recent census figures are nearly 50 per cent higher probably as the result of more accurate enumeration.) Another point is that work in recent years has shown, I think, conclusively, that the average case of leprosy seen in India is much milder than the average case seen in some other countries. These two facts, the mild form of the disease and the available statistical evidence, poor though it is, suggest that leprosy may be past the epidemic peak and may be on the downward grade. This does not mean that anti-leprosy work is not needed in India. On the other hand it may mean that conditions are favourable and that we may be able to accelerate any natural tendency in the decline in the leprosy rate.

Let us now consider tuberculosis, its incidence and severity. Here the evidence appears to point in a very different direction. Available statistics again are very poor but the indications are that tuberculosis is increasing, and increasing markedly in some parts of the country. Evidence regarding the severity of the disease in Indians as compared to other races is very limited. I can quote a very limited personal experience of tuberculosis in up-country people and in them I was astonished at the rapidity with which the disease developed and often proved fatal. Other doctors who have seen tuberculosis in India and in Europe have had similar experiences.

Benjamin (1938) has recently published an analysis of 2,158 cases in Indians. His conclusions are that tuberculosis in Indians 'is of a very serious type; it is acute, rapidly developing with little tendency to show a natural resistance and healing'. 'There is a severe exudative reaction, followed by a rapid breaking down of tuberculous tissue, with resulting cavity formation'. It should be stated that Frimodt-

Möller reports that the results of treatment of tuberculosis in Indians are quite comparable to the results obtained in Europe.

This evidence, inadequate though it is, suggests that in India the tuberculosis epidemic may be on the upward grade. If so, it means that India is facing a very serious situation and that preventive work is a vital necessity.

I will now discuss briefly some of the factors which have apparently influenced the spread of leprosy in the past and which may now and in the future influence the spread of tuberculosis in India. One important factor which has undoubtedly influenced the spread of leprosy in various parts of the world has been the development of communications, with migration of large bodies of people from one area to the other or from one country to the other, the development of commerce and industry and the recruitment of labourers from distant areas. In this way leprosy has spread from one country to another and from one part to another of the same country. In modern times industrialization has had its influence and there are indications that this factor is operating in spreading leprosy in certain parts of India. People are migrating from areas where there is little or no leprosy, to industrial areas where they mingle with other people from areas where there is much leprosy. They get infected, develop leprosy and then return to their villages and introduce the disease there. Even when an industrial population is permanently resident in an area, the concentration of people and bad housing may help the disease to spread, but when the industrial population is largely migratory, as in India, the danger is much magnified.

These things apparently influence the spread of leprosy and I think that undoubtedly they are influencing the spread of tuberculosis also.

It may, however, be argued that in western Europe the period of intense industrialization was accompanied by a decline in tuberculosis. I would point out, however, that there are three great differences between India and Europe in this respect. Firstly, industry developed in Europe when tuberculosis was apparently already at its peak and possibly on the decline. This is not so in India. Secondly, the industrial population in Europe is not largely migratory as in India. Thirdly, in Europe the development of industry was accompanied by the development of reasonably effective public health work and social hygiene in its wide sense, and also by a rise in the standard of education. I fear that we cannot yet say the same of India. Therefore, I think that the influence of industrialization on the spread of tuberculosis may be much more marked in India than it has been in Europe.

I have mentioned above some points about leprosy and tuberculosis in communities and large groups of people. Now I will briefly discuss the question of leprosy and tuberculosis in

small groups of people, in other words in families.

A study of leprosy in families shows that of young children living in contact with open infectious cases, a high proportion, sometimes between 50 and 80 per cent or more, sooner or later develop signs of the disease, and the disease tends to be severe; whereas of adults living under similar conditions, only about 5 per cent develop the disease, and the disease is often in a mild form. These findings indicate that children are more susceptible to leprosy than adults and that most serious infections are acquired early in life. Even when the disease appears relatively late in life it is often the result of an infection acquired early in life, an infection which has long lain latent.

I believe that similar studies of tuberculosis in families have given somewhat similar results. It is found, for example, that if a mother is an open case of tuberculosis, she may infect child after child and the children often get severe tuberculosis, but the husband who is living with such a wife usually does not get the disease at all, or else gets it in a relatively mild form. These facts show the relatively high degree of immunity in adults. I have been interested to read that an increasing number of workers on tuberculosis is tending to regard adult tuberculosis as often being the late result of an infection acquired in childhood, although some workers think differently. At any rate it is clear that adults get the disease much less readily than children, although the difference may not be so marked in India as it is in Europe.

The relative immunity of adults to tuberculosis is usually attributed to repeated subliminal infections early in life. It is however very difficult to explain the relative immunity of adults to leprosy on this basis. It appears to be a common natural development with age.

These facts about leprosy and tuberculosis are being more widely recognized, and this is reflected in a strengthening of the emphasis laid on the prevention of infection of children.

In leprosy you may have your diagnostic and treatment centres, your leper colonies and so on, but unless provision is made for the isolation of open cases of leprosy from children, such measures are not likely to have much influence on the spread of the disease in the community, and may even do more harm than good. For example, a leper colony with married quarters and with no proper arrangements for separation of children, as is sometimes found, may become a breeding place for lepers.

I think that the same thing may be true of tuberculosis. You may develop your tuberculosis clinics, your sanatoria, and your educational and propaganda work in the homes of the patients and in the population at large, but as long as the prevention of infection of children and young people is not attempted it will be difficult to accomplish much in the control of

tuberculosis in the community. I have seen an Indian mother with chronic tuberculosis, an open case, infect 5 children one after another. This is a very difficult matter to deal with properly. The average Indian house is too small and the average family too big and too poor to allow of reasonable arrangements to protect children and young people from infection by an open case in the house.

It seems to me that one great hope for the future lies in the direction of the development of some method of immunizing young people exposed to infection. There is of course the B.C.G. vaccine. Opinions regarding its efficacy are very divided. The development of work on the subject has been greatly handicapped by the terrible tragedy in Germany a few years ago when virulent cultures were accidentally substituted for B.C.G. vaccines, with a high mortality in the vaccinated children. At any rate it is now clear that the vaccine does no harm, and numerous competent workers are convinced of its value. A summary of the findings made in studies of the use of B.C.G. vaccine by Nègre and Goyal (1938) have recently been published. It is worthy of note that some large industrial concerns in Europe who recruit Indians for training in Europe and for future work in India, insist on such workers being vaccinated with B.C.G. before going to Europe. If further work demonstrates clearly that B.C.G. vaccine or some modification of it does produce immunity, then I think that there should be a vast field for the application of this measure in India for the immunization of contacts and of workers in industry. I only wish that in leprosy there was any prospect or hope, however remote, of the development of some similar method of immunizing to leprosy those who are exposed to infection.

I have given you some of my ideas about these two diseases, the 'twin diseases' as they have been called, leprosy and tuberculosis. My knowledge of tuberculosis is very limited and some of my ideas about this disease may be wrong. I do hope, however, that I have been able to do one thing, namely, to show how tuberculosis and leprosy are linked together and to the whole realm of medicine and public health. What does this mean in practice? It means several things. It means, firstly, that those of us who are specialists in one subject should keep in touch with other subjects, particularly allied subjects, and as far as possible with the whole realm of public health work. It means secondly that anti-tuberculosis and anti-leprosy work and other similar activities should not develop entirely independently of public health activities in general. They may be started by special organizations but they should keep in touch with general public health work and in course of time they may be incorporated in them. Thirdly, it means that the public health system should ultimately include anti-leprosy and anti-tuberculosis work as an integral part of itself. There

is far too often a tendency on the part of medical and public health authorities to regard these two diseases, and particularly leprosy, as something apart from their general sphere. I hope that as time goes on this tendency will get less, that medical schools and colleges would really give good instruction in these subjects, that practising doctors in whatever sphere they happen to work, will have the necessary knowledge, and will regard the diagnosis and management of cases of these diseases as an essential part of their work, with of course advice from experts when necessary. I hope also that public health

workers will regard anti-leprosy and anti-tuberculosis work in the same way. Real progress towards the solution of both these problems, leprosy and tuberculosis, can only be made when every doctor has become alive to their importance, and has the necessary knowledge to play his part, a most important part, in the work.

Medical News

TUBERCULOSIS NEWS FOR THE MONTH OF MAY 1939

ON account of the amalgamation of the King George Thanksgiving Fund into the Tuberculosis Association of India the Hassan Masud Suhrawardy Memorial Challenge Shield Competition which since 1932 was organized by the Fund will in future be held under the auspices of the Tuberculosis Association of India.

The competition will be open to any corporation, municipal council, municipal committee or district organization in British India or an Indian State doing anti-tuberculosis work, or any other organization, association or committee, not being larger than a district organization, which is doing anti-tuberculosis work in any of the said territories, which the central committee of the Association may from time to time admit to be eligible.

His Excellency the Governor of the N.-W. F. P. laid the foundation of a tuberculosis sanatorium at Daddar on the 11th May. The sanatorium provides for 70 beds and includes 10 beds for females. It is understood the institution is being modelled on the lines of the Union Mission Tuberculosis Sanatorium at Madanapalle.

The Bombay Tuberculosis Association has been formed with H. E. the Governor as Patron and the Hon. the Prime Minister as President of the Association.

Bombay collected Rs. 7,01,548 for the King-Emperor's Anti-Tuberculosis Fund while Ahmedabad organized a separate appeal for anti-tuberculosis work and collected Rs. 1,82,000.

In allocating funds for future work, the Association has decided to invest Rs. 2,00,000 as permanent endowment for the Provincial Association. Rs. 2,00,000 have been invested in the name of the Bel-air Sanatorium, Panchagani, and the interest thereon will be paid to this institution so long as it continues as a charitable institution and admits free patients. The Bombay Municipality on agreeing to enlarge the accommodation in the Turner Sanatorium from 40 to 80 beds, has been given Rs. 60,000 to meet one-half the cost on capital expenditure. Rs. 60,000 have been earmarked for building and equipment of clinics near the teaching hospital and the municipality and the governments have been approached on the subject. Rs. 98,190 have been allocated for clinics in the districts.

The Italian Fascist National Federation against tuberculosis has placed at the disposal of the International Union against tuberculosis six scholarships at the 'Carlo Forlanini' Institute in Rome. The Tuberculosis Association of India, who is a member of the International Union, has been invited to recommend names of young physicians already familiar with tuberculosis problems.

These scholarships, of a value of 2,000 lira respectively, plus board and lodging will be tenable for one academic year (from 15th November to 15th July) including the usual holiday periods.

The kind of work undertaken at the institute will be subject to an agreement between the director of the institute and the candidate.

The Executive Committee of the International Union against Tuberculosis on which India is represented through the Tuberculosis Association of India places at the disposal of the Governments and Associations belonging to the Union a biennial prize of a value of 2,500 French francs, in memory of the late Professor Leon Bernard, who was the Founder and, for fourteen years, the Secretary-General of the Union.

This prize will be awarded for the second time in the year 1940 to the author of an original essay on 'Conjugal Tuberculosis', in French or in English.

The essays must be typewritten or printed and must not exceed 10,000 words. They must be forwarded to the Secretary, The Tuberculosis Association of India, 20, Talkatora Road, New Delhi, not later than the 1st March, 1940. Essays approved by the Association will later be forwarded to the Executive Committee of the Union.

Should the Executive Committee decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1940, but will be offered again in the following year.

ASSAM MEDICAL COUNCIL

AN Ordinary General Meeting of the Assam Medical Council was held on Monday, 8th May, 1939, in the Office of the Inspector-General of Civil Hospitals, Assam, Shillong.

On taking the Chair, the President addressed the Council as follows:—

'Gentlemen, I welcome you once more to the deliberations of the Assam Medical Council, and I take this opportunity of making a few general observations on the agenda which is before you.'

During the past year, since the last session of the Council, one important matter has remained over for consideration and another has presented itself for the first time. The former refers to the question of "covering", regarding which you will remember that the council came to no final decision at its last session. Since then I have examined the matter, to the best of my ability, from every point of view, and I shall ask you to-day to come to a final decision on the matter. As the question is an important one, it will perhaps be desirable to place before you what appeared to me to be the underlying facts and arguments which, in due course, I shall ask you to consider.

The most important point at issue is evidently the implication of the word "covering", and in interpreting this word it is, I think, essential to consider the different conditions which prevail in the United Kingdom, where the use of the word originated, and in Assam, where the use of the word has been copied, as in most of the

Provincial Medical Acts or in the Codes of Medical Ethics framed under them, without, apparently, any clear idea of its real implications. The most important difference between India and the United Kingdom in this respect is in the legal position of registered practitioners. An examination of the Assam Medical Act makes it quite clear that there is nothing illegal in unqualified practice in Assam, nor, I believe, at present, in any other part of India. The extent of this freedom to practice is evidenced by the fact that any person, trained or untrained, can represent himself to be a doctor, whether he practises an indigenous system of medicine, or whether he practises on western lines or so-called homœopathy. There is nothing under the Assam Medical Act to prevent such persons from practising, provided that they do not represent themselves to be the registered medical practitioners, and the chief restrictions to which they are subjected are that they may not hold appointments under Government or under local bodies and that no certificate which they may issue, which is required by any Act of the Legislature, is valid in a court of law.

The insignificant effect of these restrictions as limiting practice is evidenced by the fact, with which you are no doubt familiar, that, in the larger cities of India, a certain number of graduates of the recognized Universities such as Calcutta, Bombay and the Punjab, deliberately refrain from registration under any Medical Act in order to avoid subjecting themselves to whatever measures of professional discipline the several Medical Acts prescribe, and they are thereby enabled, to their financial advantage, to ignore with impunity all the ethical principles governing advertising, association with firms of chemists, and the like. In these circumstances it is evident that there is nothing illegal in the employment, by tea gardens, of unregistered practitioners and no legal bar to the practice of their profession by unregistered practitioners, provided they keep clear of the law in the matter of the issue of certificates and otherwise and refrain from representing themselves to be registered practitioners.

The position in the United Kingdom is, I think, fundamentally different. What constitutes "covering" in the United Kingdom, as set out in the warning notices of the General Medical Council, is, in essence, an act which is (a) fraudulent, because a registered medical practitioner, by his countenance and assistance, enables an unregistered man to practise as a doctor, which otherwise would be illegal, and (b) objectionable on the grounds of public safety. I cannot satisfy myself that either of these principles can be said to apply in India, because, on the one hand, there is nothing illegal in these unregistered men practising their profession, nor, on the other hand, can it be assumed that the State regards unregistered practice as a menace to public health, since the Legislature has not taken, nor even proposed, any effective steps to abolish it, or even to limit it except to an insignificant extent, nor does there appear to me much prospect of any such restrictive legislation being placed on the Statute Book. If in the future it should be, it will then be time enough to reconsider the matter, in the meantime this council can hardly anticipate an Act of the Legislature.

Another important matter of principle which you will be invited to discuss is that of the recognition, for the purposes of registration under the Assam Medical Act, of medical degrees conferred by foreign universities. The Act provides, under section 18, that the Provincial Government, acting either independently or on the report of this council, may include in the schedule any medical diploma or title of a foreign university or medical corporation, which, in their opinion, is a sufficient guarantee that the person possessing it has sufficient knowledge and skill requisite for the efficient practice of medicine, surgery and midwifery. This section has not, so far as I am aware, ever been applied to degrees of foreign universities, and it will be for you to decide whether or not you consider that the particular applicant's medical degree is at least equivalent to the minimum qualifications recognized by the Act, and if so, whether or not the circumstances which,

as in this case, have led to the forcible expatriation of Jewish doctors formerly practising in certain parts of Central Europe, justify, on the grounds of international humanity, and in the absence of any reciprocal relations, the recognition, in special cases, of doctors who have lost their means of livelihood in their own country, and you will be asked to make recommendations to Government accordingly.

On a motion from the Chair, it was unanimously resolved "that this Council, after further deliberation, is of opinion that the association of registered with unregistered practitioners, both being employees of the same industrial concern, as on certain tea gardens in Assam, though undesirable, cannot be considered as "infamous conduct in a professional respect", within the meaning of Section 5(a) (ii) of the Assam Medical Act of 1916".

CINCHONA PROSPECTS IN INDIA

'INDIA contains enough first class land for an early resumption of cinchona growing', observes Mr. A. Wilson, Deputy Director of Agriculture, Cinchona, Madras, in an Imperial Council of Agricultural Research Bulletin.

India produces only 70,000 lb. of quinine but consumes 210,000 lb. and, therefore, imports 140,000 lb., mainly from Java. India's real need of quinine, however, has been estimated at 600,000 lb. hence the importance of extending cinchona cultivation in India.

The Royal Commission on Agriculture emphasized the importance of cheap quinine. On the advice of the Indian Research Fund Association, the Central Advisory Board of Health in July 1937, resolved that an officer experienced in cinchona cultivation should investigate areas suitable for its cultivation at the cost of production. The Imperial Council of Agricultural Research arranged and financed this investigation.

COMMERCIAL POTENTIALITIES

The two most important species utilized by cinchona plantations in India are known as *Cinchona ledgeriana* which predominates in Bengal, and *Cinchona succirubra*, the red bark variety. The latter presents certain advantages for certain soils and elevations but the former, the principal variety in Bengal, has much greater commercial potentialities, on account of its high content of the invaluable alkaloid. Mr. Wilson recommends that further attention should be concentrated on this variety.

In cinchona growing, elevation, aspect and soil are of primary importance. Most important is the definite finding that cinchona is a delicate crop requiring good plantation management comparable with orchard cultivation. If cinchona is to succeed, there must be properly organized nurseries putting out healthy seedlings which will grow into vigorous trees. Given a proper organization of nurseries and a steady offtake of bark at guaranteed prices, the cinchona plant would not be unsuitable for smaller growers but any idea that it can profitably be grown as a forest tree may be dismissed.

The investigation included a survey of likely areas and a study of cinchona soils, including potential cinchona soils, formed an important part of the investigation. The bulletin states in what areas efforts to extend cinchona cultivation are most likely to be successful.

COST OF PRODUCTION

The report contains estimates of the cost of production of cinchona bark and the prices of medicinal preparations from it—of converting the bark into quinine and into the mixed alkaloids, a cheaper preparation, commonly called totaquina. Details are given of a seven-year planting scheme which would bring Indian production up to the present level of consumption. While no great reduction in the cost of quinine is foreshadowed, the figures show that, in suitable areas, quinine can be produced in India at world market prices.

Mr. Wilson emphasizes the need for research and experiments in a number of directions. Any area selected for development should be first tested by small properly organized experiments to determine the yields of bark, the difficulties to be overcome and the cost of production. The need for further research is also emphasized. Amongst the stock of cinchona plants at present existing in the country there are undoubtedly strains of superior plantation performance containing a much higher percentage of quinine than the commercial mixed crop. By suitable methods these could be isolated and multiplied. Further experimental work is also required on the improvement of cultivation methods and in the reduction of the cost of extraction and distribution of quinine.

There are one hundred million sufferers from malaria in India calling for an annual supply of some 600,000 lb. of quinine. Immediately 38,000 acres of first class cinchona land is available, and this is distributed in Bengal, Assam, Orissa, Bhutan, Sikkim, Madras, Travancore, Cochin, Mysore and Coorg. Much of the hill land which is not yet fully explored shows promise and will require further investigation in the future.

MINERAL SPRINGS IN INDIA

Occurrence of two sulphurous springs in Riasi district, Kashmir, are reported by the Geological Survey of India.

The one, which is situated about a quarter of a mile above Khar along the Tawi river, discharges hot water only during winter. It precipitates a good deal of milk of sulphur.

The other spring is, of course, the well-known thermal spring at Tattapani. Its water is apparently possessed of certain therapeutic properties for curing skin diseases and gouty affections. This spring is visited by a large number of people from far and near. The water gives a strong sulphurous odour and maintains a constant high temperature of 70° to 80°C.

The name Tattapani is familiar in various parts of India—as in the Sutlej valley north of Simla, in the coalfield of this name on the northern border of Sirguja, in the Kopili valley in Assam, etc.—at places where thermal mineral springs occur. There are, however, numerous other localities, many well-known places of pilgrimage, where hot springs are among the chief attractions because the waters have been found efficacious in the treatment of disease.

CATALOGUE OF HOT SPRINGS

Several years ago the Geological Survey of India compiled a catalogue of the hot springs in this country, but in this connection we are in need of additional information both with regard to the radio-active and mineral character of the waters from a geological aspect and the medicinal properties of the water from a medical point of view.

Just before the Italian occupation of Abyssinia an officer of the Geological Survey of India made a special investigation of several hot springs in that country on behalf of the Emperor of Ethiopia who then contemplated establishing a health resort in his territory. The special apparatus for ascertaining the radio-active property of spring waters in the field employed in Abyssinia is now in the possession of the Geological Survey. This department has, besides, even more delicate laboratory apparatus for the same kind of work and at least three officers who are already familiar with this class of investigation.

It is understood that an exhaustive examination of the general springs of India is under consideration and it is hoped that the Geological Survey of India will shortly be able to arrange a programme. But the determination of the physical and chemical constitution of the mineral waters must be supplemented by an investigation of the cures which are said to have been effected by the various waters and for this purpose medical collaboration is necessary to complete the investigation to give the final report its greatest value.

Though mineral springs have till now attracted little public attention in India, spas and hydros in Europe which have grown up at numerous places where mineral springs occur and the therapeutic properties of the waters are beyond dispute are highly popular resorts with those who seek health and holiday.

THE CHOLERA DANGER IN INDIA: MELAS AND THE SPREAD OF CHOLERA

SINCE every large gathering of pilgrims appears to hold out a threat of the spread of cholera, the Central Advisory Board of Health at its meeting in Madras last January decided that the time had come to consider whether the authorities responsible for the health of the people should be armed with powers to enforce preventive inoculation. In order to investigate the question, the Board appointed a committee consisting of the Hon'ble Dr. T. S. S. Rajan, Minister in charge of the Public Health Department, Madras, the Hon'ble Dr. M. D. D. Gilder, Minister in charge of Health, Bombay, the Public Health Commissioner with the Government of India and the Directors of Public Health of the Punjab, Bengal and the United Provinces.

At Pandharpur, in Bombay Presidency, where an important festival attracting over a lakh and a half of pilgrims takes place at this time of the year, the Provincial Government has been able to carry out inoculations of the great majority of pilgrims in recent years. The committee appointed by the Central Advisory Board of Health will meet at Pandharpur on 26th June, in order to see for themselves the procedure adopted by the authorities there. The committee will reassemble in Poona on 28th June in order to consider its report.

The important part played in the spread of cholera by large gatherings of pilgrims at festival centres has long been recognized by public health authorities in this country. Provincial public health departments are now taking elaborate precautions in respect of such gatherings by special attention to the sanitation of the festival area, medical inspection of the pilgrims, arrangements for the segregation and treatment of persons suffering from infectious diseases and intensive propaganda for carrying out mass anti-cholera inoculation among intending pilgrims. However, the most efficient sanitation of the festival area will not suffice to ward off the danger of cholera outbreaks when large numbers of pilgrims may arrive from or pass through cholera-infected areas on their way to and from the place of festival.

The explosive outburst of cholera that followed the Hardwar festival in April 1938, and produced a large increase in the incidence of the disease in a number of provinces and states, brought prominently to public notice the necessity for the application of all available methods to ward off the danger. The value of inoculation with cholera vaccine in conferring protection against the disease is now generally recognized and it is true that, within recent years, the willingness of the people in this country to accept inoculation has undoubtedly grown. Education of the people through the propaganda carried out by provincial health authorities and voluntary organizations has been largely responsible for this result and educative efforts must no doubt continue in order to provide a background of public opinion in support of this measure.

THE BIRTH CONTROL RESEARCH COMMITTEE

THE number of people who visited and sought advice at the Birth Control Centre at 162A, Aram, Lady Jehangir Road, off Vincent Road, Dadar, Bombay 14, conducted by the Birth Control Research Committee of Vile Parle, during quarter ending 15th June, 1939, was 420, out of which 225 were males and 195 were females.

THE TINNEVELLY DISTRICT COUNCIL ASSOCIATION, PALAMCOTTAH

(TINNEVELLY BRANCH OF THE INDIAN MEDICAL
ASSOCIATION)

Monthly meeting

THE Tinnevelly District Medical Association held its monthly meeting on Saturday the 24th of June, 1939, at Papanasam, one of the most sacred places of the district, noted for natural scenery and most charming waterfalls.

Members numbering 40 gathered from all parts of the district.

The meeting began at 10 a.m. The secretary and treasurer read out the resignation letter from Lieut.-Colonel T. S. Shastri, I.M.S., the former president of the Association, which was accepted. Dr. R. V. Padmanabhan, M.B., B.S., proposed Lieut.-Colonel K. V. Ramana Rao, I.M.S., district medical officer, to be the president of the Association and seconded by Dr. L. Mahadevan, M.B., B.S., D.O.M.S. Lieut.-Colonel K. V. Ramana Rao, I.M.S., was unanimously elected as president of the Association.

The secretary and treasurer read out the minutes of the last meeting held at Srivaikuntam on Saturday the 27th of May, 1939.

BIOLOGICAL PRODUCTS STANDARDS. NATIONAL CENTRE FOR DISTRIBUTION. NEW ARRANGEMENTS AT BIOCHEMICAL STANDARDIZATION LABORATORY

THE BIOCHEMICAL STANDARDIZATION LABORATORY, All-India Institute of Hygiene and Public Health, Calcutta, has been constituted a 'national centre' for the distribution of standard preparations of biological products to those that ask for them. If laboratories intimate their requirements, the centre will import and supply the appropriate standards.

Standards have been established for many products by the Biological Standardization Committee of the League of Nations, and the actual 'standard preparation' of each kind is maintained and issued to research and manufacturing laboratories by specified institutes, such as the National Institute for Medical Research, Hampstead (under the Medical Research Council), and

the State Serum Institute, Copenhagen. For convenience of distribution of the 'standards' to those that require them, it has been found advisable to form 'national centres' in countries where biological products are manufactured. These centres receive duplicates of each standard at intervals and issue them to working laboratories for the control of their preparations.

Formerly, laboratories in India had to obtain their 'standards' from the institutes in Europe possessing each individual type, but, with the new arrangements now brought into force, it will be possible for them to get their requirements from the Biochemical Standardization Laboratory, Calcutta.

The following are the standards which will be available at the Laboratory:—

Insulin;
Pituitary (posterior lobe) standard powder;
Oestrus-producing hormones:
(i) Hydroxy-ketonic form;
(ii) Mono-benzoate of di-hydroxy form;
Male hormone (androsterone);
Corpus luteum hormone (progesterone);
Neoarsphenamine;
Sulphursphenamine;
Quabam or strophanthin;
British standard tincture of strophanthus;
Standard digitalis powder;
Adrenaline and scillaren standards.

In the manufacture of biochemical and pharmaceutical products, many of the finer qualities of which are produced in the country, India possesses a growing industry of great value. But the quality of the products has to be assessed by biological tests in relation to exact standards. The new arrangements now made at the Biochemical Standardization Laboratory are, therefore, likely to be of great assistance to this industry.

INDIAN MEDICAL SERVICE (CIVIL)

IN exercise of the powers conferred by sub-section (3) of section 244 of the Government of India Act, 1935, the Secretary of State for India has prescribed that the strength of the Indian Medical Service (Civil) shall be as given in the table below:—

TABLE

Statement showing the strength of the Indian Medical Service (Civil) under the new organization

Character of posts	Central Govt. E. H. and L. Department	External Affairs Department	Crown Representative	Madras	Bombay	Bengal	United Provinces	Punjab	Bihar	Central Provinces	Assam	N.-W. F. Province	Sind	Orissa	Total
(a) Duty posts reserved ..	30	11	7	15	12	14	14	10	9	5	7	4	2	2	142
(b) Leave reserve against (a) ..	8	3	2	4	3	4	4	3	2	2	2	1	1	1	40
(c) Other medical posts	7	5	6	4	4	3	3	2	..	38

Chronic Cholecystitis

By C. F. W. ILLINGWORTH, M.D., F.R.C.S. (Edin.)
(From the *Medical Press and Circular*, Vol. CCI,
5th February, 1939, p. 162)

CHRONIC disease of the gall-bladder occurs in more than 10 per cent of adults over the age of 40 years; it is thus by far the commonest organic cause of long-standing indigestion, and exceedingly important as a disease responsible for much chronic ill health.

In its early stages, cholecystitis is essentially a disease amenable to medical measures; later, especially if complicated by the formation of gall stones, it can only be treated satisfactorily by operation. It becomes evident, therefore, that the practitioner, upon whom rests the ultimate responsibility for treatment, must not only be acquainted with the symptoms of the early, curable stage and with those accessory measures which will enable him to arrive at a diagnosis, but he must also be able to picture to himself the stage to which the disease has progressed and thus to decide between medical and surgical measures. To do this, he must have a clear understanding of the nature and course of the pathological process in which the gall-bladder is involved.

Cholecystitis may originate independently of gall stones, or it may precede or follow the development of gall stones. Thus, on the one hand, a simple inflammation of the gall-bladder may remain non-calculous, or it may predispose to the formation of the common, multiple, 'septic' stones; whilst, on the other hand, a pure cholesterol gall stone may arise in an aseptic manner and lie in a perfectly healthy gall-bladder, or it may, by its irritative effects, predispose to the later development of inflammatory changes in the gall-bladder wall.

In general, it may be said that in the majority of cases of cholecystitis without stones, the inflammatory process is of mild type—a catarrh of the gall-bladder. At this early stage the function of the gall-bladder, as demonstrated by cholecystography, is not greatly impaired. Experience shows that in this class of case medical treatment, if carried out strictly and maintained for a sufficient length of time, will always be beneficial and sometimes curative, whereas the end-results of surgery often leave much to be desired.

It is a very different story in the more severe types of cholecystitis, which are generally associated with gall stones. Now the pathological changes are more marked. The gall-bladder, which may be adherent to surrounding structures, is palpably thickened and fibrotic, whilst microscopic examination will show replacement of the tissues of the gall-bladder wall by granulation-tissue elements and inflammatory cells. If gall stones are present the mucous membrane of the gall-bladder may be ulcerated or scarred whilst if a stone has been impacted in the neck of the gall-bladder or the cystic duct the viscus will be distended with mucus, thick, fleshy and adherent.

In these more severe types of cholecystitis the function of the gall-bladder is markedly impaired—in fact, it is converted into an inflamed, fibrotic sac, a cause of chronic disability, a source of focal infection, and a potential seat of carcinoma.

DIAGNOSIS

Chronic gall-bladder disease is to be diagnosed from a number of other affections of the abdomen and thorax.

Simple dyspepsia is a common source of difficulty in early cases. The symptoms of uncomplicated cholecystitis are mainly dependent upon interference with the mechanism of the biliary outflow, for the inflammatory changes in the gall-bladder wall lead to atony of its musculature and interfere with its normal

functions of storing, concentrating and periodically discharging the bile. Thus the digestion of fats is impaired. In the absence of gall stones or gross infection, the clinical features of cholecystitis are merely those of fatty dyspepsia, with flatulence, epigastric discomfort after meals, abdominal distension and sometimes heartburn. Often there is intolerance for fats, and the patient will have noticed that she can gain relief by avoiding such foods as potatoes, butter, eggs or fried foods. Fortunately at this early stage an immediate diagnosis is not essential for in any case the treatment is by medical measures. Only later may the question of operation be raised.

Peptic ulcer (gastric or duodenal) is readily recognized in most cases by the regularity of the pain, its precise relation to the taking of food, the relief obtained by a glass of milk or an alkaline powder, and a history of long periods completely free from indigestion. But when a stout woman comes to us complaining of similar symptoms we are apt to remember the aphorism, 'fair, fat and forty', and forget that even a patient of such a biliary diathesis may yet suffer from ulcer—especially as in such cases the characteristic deep boring pain of the ulcer is apt to be obscured by additional symptoms of flatulent type, whilst frequent recourse to the tea-cup and biscuit may tend to hide the periodicity of the pain. It was Sir David Wilkie who first drew attention to this difficulty in the diagnosis between ulcer and cholecystitis, and I have several times had occasion to confirm the truth of his observation.

Chronic appendicitis may cause some difficulty in diagnosis if the appendix is situated in the high retro-cæcal position, when the point of maximum pain and tenderness is considerably higher than usual. In doubtful cases much help is to be obtained from x-ray examination after administration of barium, for under the screen it is possible to visualize the cæcum, to roll it under the fingers, and thus to determine if the site of tenderness corresponds to the position of the appendix.

Kidney lesions in stout women may be an occasional source of difficulty if the site and radiation of the pain are not characteristic. This is just the type of case in which the value of modern aids to diagnosis is so manifest, for by pyelography and cholecystography, supplemented by a general clinical and urological examination, an exact diagnosis should always be possible.

Cancer of the colon must not be forgotten as an occasional source of difficulty. Sometimes the flatulence, the epigastric distension, the nausea and occasional vomiting produced by a deep-seated growth at the hepatic flexure may closely simulate the features of cholecystitis, whilst there may be no symptoms referable to the distal bowel.

Cardiac disease may cause misleading symptoms which may be mistaken for those of cholecystitis. In congestive heart failure there may be pain in the liver region, due to distension of the liver capsule, whilst there may in addition be a tinge of jaundice. Similar symptoms are also found in minor degrees of coronary thrombosis. Generally there is a history of precordial pain and dyspnoea, whilst any tenderness in the upper abdomen is generalized over the whole liver margin, rather than localized to the gall-bladder point. In doubtful cases, an electrocardiograph may give valuable help.

X-RAY INVESTIGATION

The method of cholecystography, introduced in 1924 by Evarts Graham of St. Louis, is now accepted as a routine procedure in the diagnosis of biliary disease.

In order to obtain reliable results every detail of the method must be given careful attention, and the x-ray apparatus and technique must be such as to give a radiograph of first quality. As a routine, a 'straight plate' should first be taken, for with modern apparatus it is possible to visualize directly a not inconsiderable number of gall stones. Thereafter the opaque dye is given, usually in the evening. It is given by mouth, and in order to avoid the risk of its causing nausea

and vomiting, as well as to facilitate absorption, I prefer to give it in divided doses with an interval of two hours, or so. From this time until the x-ray examination, which is usually done the following morning, food must be withheld completely, and fluids should be reduced as far as possible in order to minimize air-swallowing, which will tend to obscure the x-ray picture.

The interpretation of radiographs of the biliary tract requires experience and a good deal of care. A dense, well-defined cholecystogram indicates that the liver is capable of secreting the dye, that the bile ducts are patent, and that the concentrating function of the gall-bladder is not impaired. Although it cannot be assumed to exclude a mild degree of cholecystitis, such a picture is of great value as evidence that the gall-bladder is free from gross disease; whilst further confirmation is obtained if, after a fatty meal, the gall-bladder shadow is reduced in size as a result of the discharge of its contents into the duodenum.

Failure to visualize the gall-bladder is generally an indication of biliary disease—gall stones obstructing the entrance of dye into the gall-bladder or such severe inflammatory change in the gall-bladder wall as to interfere greatly with its concentrating function. In interpreting such a finding, care must be taken that the dye has been properly administered, and has not been vomited. Moreover, the x-ray film must be examined to see that the dye does not remain unabsorbed in the intestinal tract, where it will be visible as scattered opacities in the ileo-caecal region. Care must also be taken that no food has been given before the x-ray examination has been made, for this might cause premature emptying of the gall-bladder. Subject, however, to these conditions being observed, I regard absence of the gall-bladder shadow as of great significance in evidence of biliary disease.

The greatest value of cholecystography is seen in cases in which the gall-bladder contains pure cholesterol stones, which, invisible in a simple x-ray film, can be demonstrated as negative shadows when the gall-bladder has filled with the opaque dye. In such cases, the diagnosis can be affirmed with complete confidence.

TREATMENT OF CHOLECYSTITIS

Consideration of the pathology of cholecystitis makes it evident that the line of treatment must vary according to the stage to which the disease has progressed. In the early stages, when the disease takes the form of a mild catarrh of the gall-bladder, much may be done by a thorough course of medical treatment—dietetic, physiotherapeutic, choleric as well as purely medicinal.

A low-fat, low-cholesterol diet is generally advised, and although such a diet *per se* cannot influence the inflammatory process, it relieves the flatulent dyspepsia and also has a valuable effect in bringing down the weight. Regular exercises are also helpful from this point of view, and it is often quite remarkable how the symptoms of early cholecystitis will clear up in response to simple weight reduction. Even in the later stages, a slimming diet helps to mitigate the symptoms, whilst it is of very special value when operation is being considered. In obese subjects, the risks incidental to operation can be very greatly reduced by a preliminary course of gentle exercise and rigorous dieting.

The type of operation to be carried out varies according to the precise condition of the gall-bladder, but as a routine I strongly favour the performance of cholecystectomy, a clean operation which carries a low mortality and precludes all possibility of recurrent stone formation. Only in 'poor-risk' subjects in whom the gall-bladder is shrunken and adherent, in acute cholecystitis, and in cases complicated by deep jaundice, do I prefer the minor procedure of cholecystostomy.

As a routine, in operating on the upper abdomen, the use of chloroform and ether should be avoided, and especially so in biliary operations on stout women, who are so apt to be a little 'chesty' for a few days after operation. Gas and oxygen or cyclopropane anaesthesia generally suffices to give sufficient relaxation,

supplemented if necessary by a few drops of ether, and in this way much post-operative trouble can be avoided. In bad-risk cases if the gall-bladder is not too deeply placed, the greater part of the operation can be performed under local and regional anaesthesia, supplemented by light gas and oxygen during the dissection at the cystic duct.

By such means as these, and by the utmost gentleness in operative manipulation, may the risk of operations upon the gall-bladder be diminished.

Neurology: Some Modern Problems

By W. RITCHIE RUSSELL, M.D., F.R.C.P. (Edin.),
M.A.C.P. (Lond.)

(From *Edinburgh Medical Journal*, New Series,
Vol. XLVI, April 1939, p. 221)

THE study of diseases of the nervous system has for long been one of the most precise of clinical sciences. Neurologists have laid special stress on the accurate demonstration of clinical signs and their correct interpretation. The localization of function by means of the clinical study of the effects of lesions of brain and spinal cord has played a leading part in the progress of neurology. The correlation of clinical and pathological material has made it possible to distinguish a great number of diseases and syndromes with accuracy. The result of these developments was that in nine out of every ten cases of organic nervous disease a diagnosis could be made with accuracy. This diagnosis indicated the anatomical site of lesion, the pathological changes in the diseased tissue, and the probable prognosis. Unfortunately, however, the cause of the disease was in most instances unknown, and treatment was often of little avail.

Times are, however, changing: the causative factors concerned in the development of several nervous diseases have been discovered so that the treatment of many cases of nervous disease has become more hopeful. New discoveries, however, raise new problems, and I wish to give you a brief personal impression of some of these difficulties.

Deficiency diseases.—The recent discovery that certain diseases of the nervous system are deficiency diseases constitutes a notable advance. Subacute combined degeneration of the spinal cord is now a most important example of a deficiency disease. Adequate liver therapy has completely altered the outlook in this condition, for the progress of this disease can now be permanently arrested, and in many cases a striking improvement in the clinical condition follows treatment. It is, of course, essential that treatment should be begun while the disease is in its early stages, for serious degenerative changes in the spinal cord are irreversible.

In subacute combined degeneration the changes may be chiefly in the spinal cord, or they may be mainly and sometimes almost exclusively in the peripheral nerves. Whether the same deficiency factor is responsible for both the cord and peripheral nerve change is not known. The pathological changes in the peripheral nerves are similar to those seen in beriberi; the administration of vitamin B₁ by itself will not, however, benefit cases of subacute combined degeneration: intensive liver therapy is essential. From my observations on some cases of this disease, however, I have reason to think that vitamin-B₁₂ therapy is also of value in combined degeneration, especially when there is evidence of peripheral nerve involvement. An interesting feature of the pathological changes in combined degeneration is the absence of gliosis in the degenerated tracts of the spinal cord. If liver treatment has been given, however, gliosis does occur (Biggart). If we knew why gliosis does not occur in the degenerating tracts, it is at least conceivable that some therapeutic measure could be devised which would inhibit the excessive gliosis within the brain and spinal cord which aggravates many nervous diseases.

Certain forms of polyneuritis, including those due to alcohol and the toxæmias of pregnancy, are probably

pure deficiency diseases and are due to a lack of vitamin B₁₂ in the tissues. They can usually be cured by the administration of vitamin B₁₂. When the nerves are only slightly degenerated I have repeatedly observed that the improvement following a single injection of the vitamin is quite dramatic and may be demonstrable within twenty-four hours of it being given; when, however, severe degeneration has occurred, recovery can only be slow. There are many cases of polyneuritis in which the cause of the condition is unknown, but which nevertheless improve with vitamin-B₁₂ treatment. These cases show no anemia, but often have achlorhydria and a smooth atrophic tongue similar to that seen in pernicious anemia. The vitamin-B₁₂ deficiency is usually due to a faulty diet, but in some cases alimentary disturbances may interfere with the absorption of essential food factors. Improved methods of estimating the amount of vitamin B₁₂ in the blood, which have recently been devised, may make it possible in the near future to demonstrate conclusively which diseases are associated with this form of deficiency. It may be possible to establish the degree of vitamin deficiency in the individual case, and also to study accurately the effect of alimentary disorders on vitamin-B₁₂ absorption.

The interesting condition known as acute infective polyneuritis produces severe and widespread paralysis, but this disease is not due to vitamin-B₁₂ deficiency, for I have treated such a case with daily injection of 2 mg. of vitamin B₁₂ without preventing the condition from becoming steadily worse until complete paralysis of all four limbs occurred. Complete recovery did ultimately occur, but no credit for this result could be given to the treatment with vitamin B₁₂. Acute infective polyneuritis is probably the same disease as Landry's paralysis; the spreading paralysis which occurs may progress slowly or quickly, but it usually causes very severe and widespread paralysis of the muscles of the body. Fortunately the respiratory muscles often escape involvement and slow recovery occurs. Recovery is remarkably complete in those cases which survive the acute stage.

There are other forms of polyneuritis such as the post-diphtheritic type, which are, as far as is known, not deficiency diseases. It is therefore evident that the peripheral nerves undergo similar degenerative changes in several diseases in which there is no common etiological factor. Our ignorance regarding the normal metabolism of peripheral nerves handicaps attempts to investigate these conditions.

Neuro-syphilis.—Tobes dorsalis and dementia paralytica are syphilitic diseases, and appropriate anti-syphilitic therapy has a striking effect in checking their progress, though the addition of malarial treatment is necessary in cases of general paralysis of the insane. It is, however, very doubtful whether *Spirochaeta pallida* is the only factor in the causation of these diseases. There has been a striking reduction in the number of cases of neuro-syphilis during the past thirty years, and this cannot be attributed only to the more thorough treatment of the primary disease. It is becoming probable that the central nervous tissues must be in an unhealthy state before the spirochæte is able to cause these diseases. The nature of this state of impaired health is unknown, though one cannot but wonder whether some deficiency food factor may be concerned.

Disseminated sclerosis.—Disseminated sclerosis presents one of the most perplexing problems in neurology: this disease is, of course, a clearly defined clinical entity which is like no other disease. The clinical course which the disease runs is a most perplexing feature of many cases. All neurologists are familiar with patients who recover from the early manifestations of the disease, and who remain apparently in perfect health for many years; remissions lasting for twenty years or more may occur. If, the disease can spontaneously remain dormant for so long surely there must be some simple remedy. It is difficult to imagine how an infection can be responsible for a disease which behaves in this way. There are also some serious drawbacks to the conception that disseminated sclerosis

is a deficiency disease. The disease occurs in young healthy people who often appear to be living under ideal conditions as regards both environment and diet. It is uncommon in the later decades and in early childhood when deficiency diseases are most likely to develop. It is seldom met with in countries where deficiency diseases are common. It does not occur in pyloric stenosis or gastric carcinoma. Finally, I may add that I have observed striking improvement to occur in patients suffering from disseminated sclerosis who were deliberately fed on a diet low in all vitamins.

If, therefore, disseminated sclerosis is neither an infection nor a deficiency disease, what else can it be? Here again I can only speculate, but I think that it is important to bear in mind the possibility that it may be a manifestation of a metabolite disturbance affecting the whole body. Study of the other tissues and activities of the body might provide a promising line for investigation. In my experience, for example, the patient with disseminated sclerosis has little fatty tissue, and he remains thin even when he becomes unable to take exercise, in contrast to the tendency to put on weight when paralysis results from many other nervous diseases. Is it conceivable that a disturbance of fat metabolism could be responsible for the demyelination which is the striking feature of the plaque in disseminated sclerosis? There is no evidence to support such a suggestion, and yet it might be profitable to look not at the nervous system, but at the other tissues in studying this confusing problem.

CHEMICAL TRANSMISSION OF NERVE IMPULSE

The discovery that nervous impulses conveyed by the vagus nerve to the heart are transmitted by the liberation of minute quantity of acetylcholine has led to some very important advances, one of the most striking of which is that Dale and his collaborators have shown that acetylcholine is also responsible for the transmission of nerve impulse to voluntary muscle. This is obviously a most dramatic and brilliant discovery, the consequences of which are now being slowly unfolded. It may be noted, in the first place, that if a chemical substance is responsible for transmission at the myoneural junction of voluntary muscles it must be possible for that substance to be formed or liberated with great rapidity; and, further, it must be capable of rapid destruction or displacement to allow of the normal quick relaxation of voluntary muscle. The chemical substance must also be available in considerable quantity so that it can stimulate prolonged or repeated muscular activity. It is not yet known how acetylcholine is formed in the tissues, but Stedman has shown that animal tissues contain a specific enzyme, choline esterase, which rapidly destroys it.

The clinical application of Dale's work is equally remarkable. Walker found that physostigmine (and especially one of its analogues, prostigmin) temporarily relieves the muscular weakness in cases of myasthenia gravis. As physostigmine inhibits the action of choline esterase, it seems probable that its administration in this disease either conserves the supply of acetylcholine at the nerve endings or prevents its excessive destruction. It seems possible, therefore, that myasthenia gravis may be associated with a lack of acetylcholine at the myoneural junction or with an excessive activity of choline esterase. Dr. Stedman and I studied the choline-esterase content of the blood in several cases. In two of these the blood estimation was made first while muscular weakness was marked, and was repeated some months later after marked clinical improvement had occurred spontaneously. In both these cases the clinical improvement corresponded with a drop in the amount of choline esterase in the blood.

These observations exclude the possibility that in myasthenia gravis an excess of choline esterase is responsible for the rapid muscular exhaustion which characterizes this disease. It seems more likely, therefore, that this muscular condition is associated with a lack of acetylcholine at the myoneural junction.

Walker's discovery of the effect of physostigmine on cases of myasthenia gravis has provided strong confirmation of Dale's demonstration that acetylcholine is

concerned with the transmission of nerve impulses to voluntary muscle. Further confirmation has been provided by the observation by Fraser, McGeorge and Murphy that the esters of acetylcholine also lessen the muscular weakness in myasthenia gravis. Potassium salts (10 grammes of potassium chloride) taken by the mouth also relieve this weakness (Laurent and Walther) and it is known that potassium salts stimulate the liberation of acetylcholine.

It occurred to Stedman and me that the muscular condition known as myotonia might also be associated with a disturbance of acetylcholine liberation. The myotonic muscle contracts powerfully, but relaxes slowly. With repeated contractions of the muscle, however, relaxation becomes progressively easier, and soon becomes normal. Excessive liberation of acetylcholine might account for such a state of affairs, and our investigations supported this conception, for we found that cases of myotonia react to drugs in a way which is the opposite of that seen in myasthenia gravis. We were able to show, for example, that the administration of prostigmin or potassium salts aggravates myotonia so greatly that the patient may temporarily become helpless with muscular rigidity. There are other interesting comparisons between myotonia and myasthenia. Wolff reported that quinine relieves myotonia: we have confirmed this and find also that it has the opposite (a bad) effect in myasthenia gravis. One of our patients with myotonia congenita noticed that when he first awakens in the morning the muscles are quite normal, and Dr. Laurent has drawn my attention to the fact that the patients with myasthenia gravis are sometimes very weak when they first awaken. Finally, the most striking contrast between the two diseases is observed following exercise, for the condition of the myasthenic becomes much worse, while the myotonic patient improves greatly. It seems likely, therefore, that while in myasthenia gravis there is some failure in the liberation of acetylcholine, in myotonia there is an excessive liberation of this substance.

The effect of sleep on these muscular disorders brings to mind the curious condition known as sleep paralysis in which the patient on waking finds, much to his alarm, that he is completely paralysed for a few minutes. This is probably an aggravation of a normal state, for muscle tone is diminished during sleep, and many healthy people have noticed that on waking rapidly from deep sleep, muscular power is impaired for a few minutes. It is interesting to note in this connection that in cases of familial periodic paralysis, the attacks of paralysis are usually noticed on waking in the morning. One patient who suffers from a form of periodic paralysis told me that if, after waking in the morning, he went to sleep again even for a short time, he might on waking a second time find himself completely paralysed, and the paralysis would continue for two or three days. Aitken, Allott, Castleden, and Walker have shown that these attacks of paralysis are associated with a sharp drop in the amount of potassium in the blood serum: they also found that an attack of paralysis can be quickly relieved by giving a solution of potassium chloride which raises the potassium content of the serum. These workers also found that the administration of glucose or insulin brings on an attack of paralysis in those who are liable to attacks. A reduction in the amount of potassium in the blood serum normally follows the administration of glucose or insulin, but this effect on potassium is more marked in cases of periodic paralysis than in normal subjects. During an attack of paralysis in this disease the affected muscle does not contract in response to electrical stimulation of the peripheral nerves: the disturbance which causes the paralysis must, therefore, be in the trunk of the nerve, the myoneural junction, or the muscle itself. There are, therefore, some similarities between myasthenia gravis and periodic paralysis: in both the site of the disturbance must be in or near the myoneural junction, while both conditions are benefited by the administration of potassium. The two diseases are, however, very unlike in most respects, and one important difference is that prostigmin, which benefits myasthenia, has no good effect in cases of

periodic paralysis. It seems unlikely, therefore, that periodic paralysis is caused by a disorder of the chemical transmission of nerve impulses: it is more likely that that abnormality affects the muscle fibres directly. The association of the attacks of paralysis with sleep is striking and, as I have already mentioned, sleep may have a definite effect on both myasthenia and myotonia. In attempting to throw light on the nature of these diseases, therefore, we are anxious to learn more regarding the bodily changes occurring during sleep. During sleep there is loss of muscle tone, and this fact when considered along with the effect of sleep on some cases of myotonia and myasthenia to which I have already referred, suggests that during sleep there is some alteration or inhibition of the chemical transmitter of nerve impulses.

In considering the effect of sleep on certain diseases of the nervous system, it is necessary to refer to these remarkable conditions, cataplexy and narcolepsy. These two conditions are closely related to each other for they often occur in the same patient. Cataplectic attacks cause no impairment of consciousness but sudden atonic paralysis which lasts usually for less than a minute. Emotion, particularly laughter, is the usual precipitating cause. One patient I saw recently was much inconvenienced by cataplectic attacks. A slightly amusing remark heard while descending an escalator made him so weak that he was unable to step off the moving platform. A good shot at golf would make him drop paralysed to the ground; even a successful move at the game of draughts had a similar effect. The victim of narcolepsy, on the other hand, falls into a deep sleep on several occasions every day. Ephedrine has a striking effect in relieving many cases of both narcolepsy and cataplexy. It is interesting to note that ephedrine also benefits certain cases of myasthenia gravis.

If one compares cataplexy, familial periodic paralysis, and myasthenia gravis, certain similarities emerge: all these conditions cause muscular weakness; no definite pathological changes are known in connection with these diseases; all are affected in some way by sleep or are related to a disturbance of sleep. All these conditions seem to be an exaggeration of a normal reaction; the muscular helplessness which normally accompanies violent laughter resembles cataplexy: the paralytic attacks in familial periodic paralysis always follow sleep, while deep sleep in the healthy person may be followed by a short period of muscular weakness (sleep paralysis). Finally, it is noteworthy that, while in myasthenia gravis the muscles become fatigued rapidly, muscle fatigue is a normal effect of exercise. These diseases seem, therefore, to consist of an exaggeration of normal bodily reactions. Further, they all affect the motor system, all have features in common, and yet are unlike in many respects. The disturbances of function which are associated with these diseases occur at different levels of the motor system. In myasthenia gravis the fault is at the myoneural function, in cataplexy the effect is produced somewhere in the brain, while in periodic paralysis it is probably in the muscles themselves. In attempting to unravel this complicated problem, the further investigation of the effects of sleep on the body in general and the nervous system in particular might well prove to be helpful.

It has gradually become probable that the transmission of all nervous impulses from neurone to neurone, and from neurone to organ or tissue, is dependent on the liberation of a chemical substance at these nerve junctions and endings. Research work is now proceeding in an attempt to determine the chemical concerned with nerve transmission in the brain and spinal cord. There is some evidence to suggest that acetylcholine is, to some extent, concerned. Stedman has demonstrated the presence of acetylcholine in the ox's brain while Henderson and Wilson have demonstrated that the injection of acetylcholine into the cerebral ventricles has a direct effect on the brain.

These investigations may prove to be of very great value for if we knew the chemicals concerned, say, in stimulating the motor system of the brain, and if we

know the way in which these chemicals are formed in the tissues, means might be devised for controlling cerebral and spinal motor activity to a degree that is at present impossible.

We are, as yet, entirely ignorant regarding the chemical concerned with sensory nerve transmission. The absence of sensory phenomena when acetylcholine is administered suggests that this chemical is not concerned with sensory nerve conduction. It is interesting to speculate on the possibility that disturbances of the chemistry of nerve conduction might be the cause of certain diseases of the brain and spinal cord. Take, for example, the system diseases in which certain nerve tracts undergo degeneration. Progressive muscular atrophy is a striking example of such a disease, for in it the motor pathways undergo progressive degeneration while the sensory pathways remain intact. It is conceivable that the chemical transmission in the motor system could become disturbed in such a way as to cause damage to the nerve-cells with which it is connected. It is interesting to note in this connection that the muscular twitchings which occur after the administration of prostigmin are indistinguishable from those which occur spontaneously in the muscles in cases of progressive muscular atrophy. Such ideas are very speculative, but speculations are sometimes valuable for they may suggest lines of investigation for the research worker. The conception of the chemical transmission of nerve impulse has obviously opened up entirely new lines of research into the physiology and pathology of the nervous system.

EPILEPSY

Finally, I should like to say a few words about epilepsy. In a recent paper on rhythm in epilepsy, Griffiths and Tylor Fox have drawn attention to a problem which has been much discussed, especially in recent years. It is a matter of common knowledge that the individual epileptic may have his fits at certain times only of the day or night. The fits may occur only during sleep, or while falling asleep, or after waking; or they may occur only during the day. A long interval rhythm in epileptics is seen in those cases which have a fit or a series of fits at regular intervals of, say, a fortnight, a month, or every two or three months. The focus of cerebral irritation in these cases seems to develop gradually an increasing disturbance which culminates in a violent discharge, and the ultimate fit seems to allow the brain to return to normal for a further interval. In this type of case, therefore, the occurrence of a fit seems to give temporary immunity to further fits. The fit itself, therefore, appears to relieve the conditions which have led to the convulsion occurring, and to correct temporarily the abnormality of the brain tissue which leads to a convulsion. The transmission of nerve impulses at the cerebral cortex is probably as much dependent on a chemical substance as is the transmission at the myoneural junction; abnormal activity at the cortex

must, therefore, cause or be caused by an excessive liberation of the chemical transmitter. If we attempt to correlate this conception with the suggestion that in certain cases the occurrence of a fit allows the cerebral cortex to return to a more normal state, one is tempted to suggest that an epileptic fit may be preceded by an abnormal accumulation of chemical transmitter, and that this is dispersed when the fit occurs. In this connection it is interesting to note that mental activity is known to lessen the liability to a fit occurring. I remember a patient who had 20 to 30 minor fits after waking up each morning; if after waking he at once proceeded to read some difficult Greek which required considerable concentration he was able to reduce the number of attacks to three or four each morning. Mental exercise, therefore, appears to make the physiological state of the epileptic's brain more normal. One is tempted to point out that in cases of myotonia muscular exercise makes the physiological state of the myotonic's muscles more normal. Can there, therefore, be anything analogous between myotonia and epilepsy? Can they both be associated with an excessive accumulation of chemical transmitter at the myoneural junction and cerebral cortex respectively? The possibility is at least worthy of investigation.

Recent investigations with the electroencephalograph such as those of Gibbs, Gibbs, and Lennox describe a different form of rhythmical disturbance in epilepsy. The electroencephalograph records minute changes of electrical potential in the brain through electrodes applied to the scalp. In many normal people rhythmical waves of change of potential occurring at the rate of about 10 per second can be demonstrated by this means. In cases of epilepsy, however, abnormal and irregular waves appear, especially when a fit is imminent. In one patient daily records were made by Gibbs, Gibbs, and Lennox for over six months and most of the *grand mal* seizures were correctly predicted by means of the changes in the electroencephalographic tracings found on the mornings of the days the fits occurred. These authors have studied the electroencephalograms of 400 epileptic patients, and they conclude that 'the pathological physiology of epilepsy is a paroxysmal cerebral dysrhythmia'. Their term 'pathological physiology' interests me, for I have been trying to suggest to you that diseases such as myasthenia gravis, familial periodic paralysis, and myotonia are due to disturbance of physiology without there being any histological abnormality. The study of these rare diseases which affect the motor system has already thrown light on the physiology of muscle and nerve. We can only hope that the study of epilepsy by these new methods of electroencephalography will throw light not only on the physiology of the brain, but will show us how to improve the treatment of the epileptic.

To conclude, I must apologise for giving you little information which will be of value to you in your practical work. I hope, however, that I have been able to demonstrate that recent developments in neurology are of no little interest and importance.

Reviews

THE DYSENTERIC DISORDERS: THE DIAGNOSIS AND TREATMENT OF DYSENTERY, SPRUE, COLITIS AND OTHER DIARRHOEAS IN GENERAL PRACTICE.—By Phillip Manson-Bahr, C.M.G., D.S.O., M.D., F.R.C.P. 1939. Cassell and Company, Limited, London (La Belle Sauvage, E.C.4). Pp. xiv plus 613, with 9 colour, and 14 black and white plates and 106 illustrations in the text. Price, 25s.

The literature on dysentery and allied diseases is poor. The monographs that have appeared during the last quarter of a century have been indifferent

productions and some have been definitely bad, so that one has had to rely on chapters in books and encyclopædias; in these, the writers have been cramped for space and have therefore not done full justice to their subjects. To produce a good book on this difficult subject takes courage, experience, and great powers of discrimination; hitherto those with the experience have lacked one or other of the necessary qualities, so that either they haven't written at all or have produced a mass of undigested information, whereas others with courage have lacked the necessary practical experience. No one could possibly question

the courage or the experience of the present writer, and this book has shown that his judgment is good and that his powers of discrimination are developed to a high degree.

The scope of this book is wider than his abbreviated title suggests, and it might well have been called the *Dysenteric and Diarrhoeal Disorders*. This wider scope is however indicated in the subsidiary title.

The note which indicates the practical key in which the whole book is written is struck at the very beginning, as the first chapter is on differential diagnosis and the enumeration of the procedures that should be undertaken in investigating a case, whereas the second is on methods of examination of the patient and includes a descriptions of sigmoidoscopy.

Then, for the time being, the author deserts the practical plane and the third chapter is one which would presumably be described by Henry Ford as 'bunk', but to the reviewer was one of the most interesting chapters in the book; it is, need it be stated, an historical one. In this and the next chapter, which is on geographical distribution, it is made very clear that the disease is not truly a tropical one, but a disease of sanitarially backward areas and of occasions when there is a break-down in the sanitary organization. The fifth chapter, on classification, concludes the introductory part of the book.

Bacillary dysentery, rightly, claims first attention; there are four chapters, which cover a hundred pages, on this subject, but the largest share of space falls to amebiasis, to which six chapters are devoted. This historically and pathologically more interesting disease has often usurped the claims of the more deadly bacillary disease to the attention of the physician, sometimes with disastrous results, but it is a subject with far more facets and the writer could scarcely have done it full justice in less space. Under the same main heading, protozoal dysenteries, there is a chapter on balantidiasis, giardiasis and the flagellate dysenteries; in this chapter are included sections on plasmodial and leishmanial dysenteries.

The next chapter is on the important helminthic dysenteries. There is an important chapter on cholera. Recent work is reported, but perhaps too much space is devoted to past and obsolete observations and one is conscious of a lack of personal experience on the part of the writer. Statistics are quoted from the Calcutta Medical Hospital (*sic*), a hospital which it is hard to identify. Roger's saline treatment is naturally given preference, but a number of 'specific' treatments are also discussed. The inexperienced reader will find it difficult to choose between these, and he receives no help from the author. Bacteriophage is dismissed a little too summarily and more space is given to the very limited work that has been done with serum. Reference is made to the essential oils, the introduction of which is, for some reason, attributed to Tomb, though they have been used as a stock mixture in the Army dispensaries in India since the time of the East India Company. The association of this name with this mixture is particularly unfortunate, as, in the reviewer's experience, it is deadly form of treatment when given alone.

The chapter on sprue and hill diarrhoea is perhaps one of the best in the book. Here the writer has given full acknowledgment to the work of his colleagues in London, though it is a subject in which he has had very considerable experience. This chapter is followed by one on idiopathic steatorrhoea and coeliac disease, non-tropical conditions but pathologically associated with sprue, and their inclusion here is very suitable.

Other important chapters are on mucous colitis and ulcerative colitis.

The whole book forms a most important contribution to a very difficult subject; it is a book that will have a wide appeal in any country, but we particularly recommend it to all medical workers in tropical countries.

THE BRITISH ENCYCLOPÆDIA OF MEDICAL PRACTICE: INCLUDING MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY AND OTHER SPECIAL SUBJECTS.—Under the General Editorship of Sir H. Rolleston, Bt., G.C.V.O., K.C.B., M.D., D.Sc., D.C.L., LL.D. Butterworth and Company, Limited, London. (To be completed in 12 volumes.) Sold in complete sets only. Cash price, Rs. 25 per volume. Also available on the instalment system at Rs. 10 per month. Price, Rs. 26-8 per volume. Only available from Messrs. Butterworth and Company (India), Limited, Calcutta. Volume XI. Illustrated. Pp. xxi plus 676 plus 54

This volume covers subjects from scarlet fever to testis, undescended. Chance appears to have made it a volume of skin diseases, as not only is there a large section of 120 pages headed 'skin diseases', but there is one almost equally long on syphilis, and minor chapters on seborrhoea, seborrhoeic dermatitis, and scleroderma, not to mention the exanthemas, smallpox and scarlet fever.

The section on skin diseases does not claim to be a comprehensive one and there are 23 cross references to other sections, a list which again does not claim to be complete. The subject is discussed under five headings, each contributed by a different writer—affections due to insects and acarines by Arthur Whitfield, occupational diseases by S. A. Henry and Sibyl C. Horner (H. M. Medical Inspectors of Factories), locally inoculated infections by L. Forman and E. H. Koerner (both of Guy's Hospital), tuberculosis by Arthur Burrows, and tumours by Sidney Thomson. The various conditions are well described and the section contains a large number of relevant illustrations, including two coloured plates. Other skin diseases are dealt with under their individual names throughout the encyclopædia, and were they collected together into one volume they would provide as complete and comprehensive a book on the subject as one could wish for.

The section on syphilis is by Colonel Harrison. It is a comprehensive study by a man who has made the subject of venereal disease his life work: again the section is well illustrated.

J. W. McNee (inevitably) and John McMichael have written the section on spleen diseases. It is a surprisingly short chapter for so important a subject, and, though it is excellent as far as it goes, the writers have perhaps chosen the safest course and have ignored tropical splenomegalies.

Tropical sprue is dealt with, appropriately, by Hamilton Fairley. The various theories for its aetiology are discussed, but he has not wasted much time on these as most of them are easily dismissed. He considers that the suggestion that the disease is due to 'extrinsic factor' deficiency can be negated, as patients of the class that one most frequently sees have lived on a good mixed diet, and he considers that the cases on which this theory was founded are not sprue but tropical macrocytic anaemia. The reviewer agrees with this point of view; it is possible to improve the blood picture of a sprue case by giving liver extract, but the disease can only be cured by combining this with dietary treatment. The reviewer does not, however, agree that the disease is 'very rare' amongst Indians.

Volume 11 is a good one and perhaps one of the best volume of this excellent 'system'.

RECENT ADVANCES IN MEDICINE: CLINICAL LABORATORY THERAPEUTIC.—By G. E. Beaumont, M.A., D.M. (Oxon.), F.R.C.P., D.P.H. (Lond.), and E. C. Dodds, M.V.O., D.Sc., Ph.D., M.D., F.R.C.P. Ninth Edition. 1939. J. and A. Churchill, Limited, London. Pp. xvi plus 431. Illustrated. Price, 15s.

The *Recent Advances Series* has become so firmly established in medical literature that it is hard to believe that the first volume was issued only 15 years ago. This volume was appropriately *Recent Advances*

in *Medicine*; the volume under review is the ninth edition of this book. The eighth edition was published three years ago; this is the longest gap in the history of the book. Much has happened in these three years and very extensive revision was necessary, and has been undertaken; many chapters have been completely rewritten and new ones have been added. There have been considerable changes in the type used; this has allowed a 10 per cent increase in the number of words on each page without any sacrifice in readability. The references have been rearranged so that the same number occupy about half the space they did in the last edition. The result is that there has been a slight reduction in the number of pages and a considerable increase in the matter presented—a notable achievement on the part of the publishers.

The authors are also to be congratulated on their judgment in selection of subjects for inclusion. The first chapter is a very concise account of the sulphanilamides and allied drugs including M. & B. 693; this of course is an entirely new chapter. The next is a chapter on vitamins which is a little disappointing; the table was in the last edition (and possibly in earlier editions too) and should be replaced. Vitamin B₁₂ is now known to contain at least three distinct fractions, but one would not gather this fact from the account given, and there seems to be some confusion between the rat dermatitis and the pellagra fractions; the term nicotinic acid is not used.

Chapter III on the kidneys has been modified and considerable changes have been made in the next chapter on the dietetic treatment of diabetes. In fact additions and modifications have been made in nearly every chapter.

The method of King, Haslewood and Delory for performing the van den Bergh test has been added. The authors say that normal persons show 0.2 mgm. to 1.7 mgm. per 100 c.cm. of plasma bilirubin by this method, but add that most normal results are below 0.8 mgm. Further down in the same page, they give the normal limits as 0.2 to 0.5 units. In any case the 'unit' is an arbitrarily-chosen unit of measurement, corresponding to 0.5 mgm. per 100 c.cm. of blood, which is best avoided, as its use only leads to confusion. It will be seen that the two normal ranges given not only do not coincide but barely overlap. No attempt is made to explain this discrepancy.

The method of estimating the sedimentation rate with a hæmatocrit tube which can then be centrifuged and a correction made for anemia is described.

Much has been done with sex hormones during the last few years, both in treatment and diagnosis, especially the diagnosis of pregnancy. A good account is given of these advances in chapter X.

In conclusion one can say that the authors and publishers have effected considerable improvements in an already excellent book.

EVANS' RECENT ADVANCES IN PHYSIOLOGY.—

Revised by W. H. Newton, M.D., M.Sc. (Manch.). Sixth Edition. 1939. J. and A. Churchill, Limited, London. Pp. xi plus 490, with 109 illustrations. Price, 15s.

In the title of this book there has been a slight departure from the usual practice, in that the name of the original author is incorporated. This is a nice compliment to one of our greatest living physiologists, and in this case there is the further excuse that he himself contributed a new chapter in the last edition and has revised it for this, but the practice is not quite in keeping with the spirit of the series. Such a book is a selection from the moving picture of physiology of representative 'stills', which need bear little relationship to those of an earlier selector.

There are in this edition four completely new chapters: Chapter I on the physiology of bone summarizes work done mostly during the last ten years on this subject, but has avoided as far as possible reference to the effects of dietary and the action of the parathyroid hormone as introducing too much that is uncertain; the physician may feel that this is providing apple tart without any apple in it, but

there is much important work summarized in the 45 pages of this chapter which will give the young physiologist plenty to think about. The next chapter is a short one and devoted entirely to a description of the Carrel-Lindbergh perfusion apparatus.

The new chapter on carbohydrate metabolism is a stimulating one. The author draws attention to the fallacy that an increase in the normal blood sugar must be due either to increased intake or decreased utilization. As he points out, hyperpyrexia may be due to either increased heat production or decreased loss, but it is much more frequently due to some other cause which raises the point at which the balance between these two different actions is achieved: it is the same with carbohydrate metabolism, and one could conceive a state of affairs where the blood-sugar level was raised to say 150 mgm. per 100 c.cm. of blood without disturbance in intake or utilization, though if it rose above 180 mgm., the renal threshold, a new factor would be introduced.

The last chapter, and the fourth new one, is on the cortical control of muscular movements. It includes reference to much recent experimental work with monkeys.

Physiology provides a wonderful field for the research worker; our knowledge on every aspect of the subject is so incomplete. The author of this book has in many instances stated the problem and then presented the facts, as a series of tag ends that are waiting for others to pick up and join together; in some cases he has loosely knotted these ends, but in others he has not even done this.

It is a most interesting and stimulating book which we can thoroughly recommend to the young physiologist, and all physiologists should be young at heart.

RECENT ADVANCES IN OBSTETRICS AND GYNÆCOLOGY.—By A. W. Bourne, M.A., M.B., B.Ch. (Camb.), F.R.C.S. (Eng.), F.R.C.O.G., and L. H. Williams, M.D., M.S. (Lond.), F.R.C.S. (Eng.), F.R.C.O.G. Fourth Edition. 1939. J. and A. Churchill, Limited, London. Pp. x plus 366, with 98 illustrations. Price, 15s.

Those readers who are familiar with the earlier editions of this book were looking forward to a fresh edition, in view of the rapid advance in this branch of medicine. They will be grateful to the authors for bringing out this book where a good deal of interesting and useful information has been presented in a short and precise form. To each chapter has been added an excellent list of important references about the subject-matter dealt with. This should prove of great use to advanced students, practitioners and consultants in this specialty.

It is very difficult to single out any particular chapter or chapters for special appreciation. All of them have been interestingly written.

In the obstetrics part we single out the chapter on puerperal sepsis for special praise. We are of the opinion that we have not come across such a complete and masterly summary of the latest investigations of this complication of pregnancy in any recent publication on this subject. After going through this chapter one feels that one has got all the latest information that one may need when called upon to treat a case of puerperal sepsis.

The last edition of this book contained two chapters on maternal mortality and fetal death. These two chapters have been omitted in the present edition. Perhaps the authors did not want to add to the pages of the book.

There are several well-written chapters in the gynæcological part of this book. There is a detailed description and discussion of the various methods adopted in treating uterine cancer. The illustrations of the different radium applicators used in the big clinics will be particularly appreciated by practitioners in distant parts of the world who may not have the opportunity of direct knowledge from such clinics.

The chapter on sex hormones has been very ably written. The authors should be congratulated for the clever way in which they have described the various complicated experimental facts and clinical observations in connection with the discussion of the action and use of the hormones.

Mr. Wilfred Shaw's masterly description and classification of ovarian tumours has been included as a chapter in this section. This being one of the latest and important contributions to gynaecological pathology: the authors have been well advised to include it in their work.

The binding and printing of the book was good in the last edition and so it is in the present. More illustrations have been added; and these have served their purpose well.

M. S.

(a) **RECENT ADVANCES IN HÆMATOLOGY.**—By A. Piney, M.D., Ch.B. (Birm.), M.R.C.P. (Lond.). Fourth Edition. 1939. J. and A. Churchill, Limited, London. Pp. viii plus 312, with 8 coloured plates and 34 text-figures. Price, 15s.

(b) **PRINCIPLES OF HÆMATOLOGY. WITH 100 ILLUSTRATIVE CASES AND 155 ILLUSTRATIONS INCLUDING 168 ORIGINAL PHOTO-MICROGRAPHS AND 95 ORIGINAL CHARTS AND DRAWINGS.**—By R. L. Haden, M.A., M.D. 1939. Henry Kimpton, London. Pp. 348. Price, 21s.

(a) THE authors in this excellent series give different interpretations to the meaning of the words 'recent advances', and it is obvious that the publishers make no attempt to influence their authors; this is probably a wise course.

Fortunately, none of these authors has provided a book of 'stop press' annotations on his subject, but the majority have given résumés of the old—but still accepted—teaching in order to provide stepping-stones for the newer knowledge that they present. The author of this book has gone further: he has written what might be described as a 'primer' on the subject of hæmatology, in which he has certainly incorporated some of our new knowledge.

It is a book designed for the student; he will find it easy to understand and the author takes few risks in assuming prior knowledge on the part of the reader, so that the practitioner who has forgotten his physiology and histology can read it without embarrassment. Further, the book is well illustrated; the numerous coloured plates should help anyone to put a name to the cells he sees in the peripheral blood smear (or in the sternal puncture fluid, should he be a little more advanced in his outlook than the author), but whether it will be the name that other hæmatologists apply to that cell is a different matter; hæmatological nomenclature is still in a chaotic state.

There is a very useful plate showing the appearance of the different cells in a histological section of bone marrow which is so very different from that of the same cells in a bone marrow smear; if the illustration has a defect, it is that it is too diagrammatic.

The author has adopted a very conservative attitude; he has remained silent on the recent classifications of the anæmias, there is little said on the subject of the size of red cells and less about their volume, reticulocytes are mentioned but there is little about the importance of reticulocyte crises in estimating the effects of treatment, and the author doesn't seem to have heard of sternal puncture. There is practically no reference to tropical macrocytic anæmia and we did not notice any to the work of Wills. On the other hand some rare and interesting blood diseases are described in detail.

It is a book that we can recommend to the practitioner who, finding himself quickly out of his depth in more advanced books on hæmatology, has given up the uneven struggle.

(b) This second book is the complete antithesis of the first. Hæmatology is reduced to mathematical formula; you take the blood, put it into a machine, read the answer, apply a table or graph, and you have the correct diagnosis, about which nobody can argue. Science displaces art.

The author has described modern hæmatological methods in such a way that no one could fail to understand what he is trying to convey. There are diagrams on almost every page, and, if these are not always quite self-explanatory, by the time the student has worked out their meaning, he will certainly have acquired a more complete grasp of the subject, than if he had simply read it up in the text. There are however other figures that are a little too 'popular' in their conception and do not bear critical examination.

[In mitigation of this criticism it should be added that the reviewer has already copied and used for teaching purposes many of the author's figures from the *Journal of Laboratory and Clinical Medicine*, where they originally appeared.]

The reader is made acutely conscious that red blood cells vary in size, thickness, and volume, in gross hæmoglobin content, and in the concentration of their hæmoglobin, and are not simply flat discs which vary in number, shape and staining reaction, which was the impression usually left in the mind of the student by the teaching of the older school of hæmatologists; also that the blood picture is not static, but dependent on an even balance between blood formation and blood destruction and that anæmias are due to disturbance of this balance. But, on the other hand, it is all made too mechanical and too easy, and in practice the physician will find that seldom can the individual case be reduced to such a simple formula.

There are many features in this book which appeal to the reviewer. Especially the emphasis that is laid on the 'normal' blood picture and its variation in different age groups, in the two sexes, and in different communities. However, in view of these great differences is it reasonable to employ 'indices'; these necessitate the adoption of a normal standard which in these circumstances has to be changed continually, or chosen arbitrarily. Why, when you can give the mean hæmoglobin content of a cell an absolute value (e.g., 29 micro-microgrammes), introduce a colour index which is dependent on two 'standards', for hæmoglobin and red cells, which, even as applied to normal adult males, are given variously as from 13.8 to 17.2 grammes and from 5,000,000 to 5,500,000, respectively, by different workers, and show a wider variation when infants and females have to be considered? The author further suggests that each hæmatologist should work out his own normal standards, by examining the blood of ten 'normal persons'. It is suggestions of this kind that give the adherents of the older conservative school of hæmatology an opportunity to jeer at the pseudo-accuracy of the modern hæmatologist, and justify their use of blotting paper and faded colour scales.

We commend this book—to the teacher in this country (but we beg him not to hand it over to his artist or photographer with an order to copy or make slides of all the figures; there are some very useful graphs and diagrams, and, if careful selection is made, he will find them invaluable for demonstrating the modern conception of the physiology of the erythron and the mechanism of anæmia)—to the hæmatologist of the advanced mechanical and statistical school, as a solemn warning—and to Dr. A. Piney, for he will, we are sure, find in it complete justification for his conservative, if not reactionary, attitude towards the subject.

Although more books like the former come from Great Britain and more like the latter from America than *vice versa*, these two books are not typical productions of the British and American schools of hæmatology, respectively, and, we are thankful to say, better books on hæmatology have emanated from each country.

L. E. N.

A HANDBOOK ON DIABETES MELLITUS AND ITS MODERN TREATMENT.—By J. P. Bose, M.B. (Cal.), F.C.S. (Lond.). Third Edition. 1938. Thacker, Spink and Company (1933), Ltd., Calcutta. Pp. xvi plus 272. Illustrated. Price, Rs. 7-8

Dr. Bose's well-known book on diabetes is one of the best on the subject. To the general practitioners in India, particularly to those in Bengal, where the incidence of diabetes is so high, this book has always been of great help in the management of their diabetic patients.

The third edition of this book has been brought up to date, and the outstanding advances in the subject made during the recent years have been incorporated. The different chapters have been thoroughly revised and partly rewritten, and new chapters have been added. The section on carbohydrate metabolism has been rewritten in the light of recent work of the author on phosphate and cholesterol metabolism. There has been some remodelling of the author's system of dieting and some new scales of diet have been incorporated. A new chapter on protamine zinc insulin discusses the 'insulin retard' group of preparations. The author is of opinion that 'protamine zinc insulin is a powerful weapon and is destined to prove more useful than ordinary insulin, its introduction certainly constitutes a step forward in the treatment diabetes'. This chapter is, by the way, reprinted from the author's recent article in this journal (*Indian Medical Gazette*, Vol. LXXIII, p. 390).

The different scales of diet, recipes suitable for diabetic patients, the tables dealing with the carbohydrate, protein and fat content, and calorific value of common food-stuffs of European and Indian dietary, will be found invaluable by physicians and their diabetic patients in planning suitable diets.

The reviewer believes that this book will prove extremely valuable to those for whom it is meant.

P. C. S. G.

GONORRHOEA IN THE MALE AND FEMALE: A BOOK FOR PRACTITIONERS.—By P. S. Pelouze, M.D. Third Edition, thoroughly revised. 1939. W. B. Saunders Company, Limited, London. Pp. 489. With 144 illustrations. Price, 27s. 6d.

In the preface, it is stated that this is not a textbook on gonorrhoea; it is just a simple story simply told. It is not difficult to discover that the well-merited success of this book is largely due to this fact. The present edition has been brought completely up to date by the inclusion of such subjects as hyperthermia, sulfanilamide and its derivatives and the oestrogenic hormones. Almost all the chapters have been amplified or rewritten; many new illustrations, charts and tables have been added and finally the author has kept before him the great change, since 1928, in the attitude of the profession towards this disease. Previously, it was 'publicly unspeakable and medically an outcast' but now the profession has awakened and his highly critical.

This book is conveniently divided into three parts. The first part deals with gonococcal infections in the male, the second with gonorrhoea in the female and the third with the medical profession and gonorrhoea control. The chapters on sulfanilamide are very informative and the author has taken pains to describe the symptomless carrier state produced by this drug. The efficacy of sulfanilamide preparations in gonorrhoea is not unknown to the public owing, largely, to the activities of sensational journalism. In some parts of North America, where certain women, we are told, have to undergo a form of 'medical inspection', they urinate and take a vaginal douche before they visit their doctor, and even take sulfanilamide for a few days prior to the 'study'. Sulfanilamide is being sadly abused in this way in the hands of unscrupulous persons.

We have much pleasure in recommending this book to the medical profession. The printing, binding and illustrations are all excellent. A useful index is appended.

P. N. R.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE THYROID.—By James H. Means, M.D., and Edward P. Richardson, M.D. ('Reprinted from Oxford Monographs on Diagnosis and Treatment'.) 1938. Oxford University Press, London and New York. Pp. vii plus 367. Illustrated. Price, 21s. Obtainable from Oxford University Press, Bombay and Calcutta

The present volume forms a part of the series of the excellent monographs on 'Diagnosis and Treatment' published by the Oxford University Press. The joint authorship of an eminent physician and of a surgeon, and the fact that the work has been based on the personal experience of the authors over a period of twenty-three years tend to enhance the value of the work.

The object of the present work is to provide for the practitioner a convenient handbook containing up-to-date information regarding the various disorders of the thyroid gland, the modern methods of diagnosis and the more generally accepted methods of treatment.

The book covers the entire field of the diseases of the thyroid gland. It begins with the history of the development of our knowledge of the thyroid gland and then goes on to describe the functions and diseases of the thyroid. The principles underlying the diagnosis and treatment of the thyroid diseases have been very ably and clearly described in a separate chapter. Two special chapters have been devoted to discussion of the condition of 'exophthalmic goitre', one dealing with the aetiology, pathology, differential diagnosis, the clinical course, etc., and the other dealing very exhaustively with the various methods of treatment of the condition about which so many diverse views still exist. Summing up the discussion of the treatment of this condition the authors suggest that the best treatment at present for exophthalmic goitre, is 'sub-total thyroidectomy in an iodine remission'; the authors have cited numerous authorities in support of their claim.

The book has been written in a clear, lucid and simple style and it gives as much up-to-date information as may reasonably be required for the use of general practitioners, and we have pleasure in recommending the book.

J. P. B.

ROYAL NORTHERN OPERATIVE SURGERY.—By the Surgical Staff, the Royal Northern Hospital, London, and edited by Sir Lancelot Barrington-Ward, K.C.V.O., M.B., F.R.C.S. 1939. H. K. Lewis and Company, Limited, London. Pp. x plus 551. With 463 illustrations. Price, £2 2s.

ALTHOUGH there is no dearth of excellent handbooks on operative surgery, it will be agreed that a new one written by the surgical staff of the Royal Northern Hospital of London has more than justified its publication. It is the work of several experienced hands under the distinguished editorship of Sir Lancelot Barrington-Ward and is designed to represent, as far as possible, the practice of this well-known hospital. In order to keep the volume within reasonable limits and to make the work as practical as possible, the special subjects together with all archaic procedures have been omitted; as a rule 'one well-tried way of performing any given operation has been presented'. In short, we can describe this book as an epitome of modern surgical practice and technique.

Considering the vastness of the scope of modern operative surgery, the bulk of this book, consisting of 552 pages, may be considered to be very handy. Another noteworthy feature is the excellence of the illustrations, of which there are no less than 463 in this book. In fact, all the well-known traits of

Mr. Hamilton Bailey's works are reflected throughout. Altogether there are thirty-two chapters in this volume, adequately covering the requirements of general surgery. The first seven chapters deal with the head and neck with particular emphasis on important subjects such as the thyroid gland and the tongue. Then follows a chapter on the thorax, in which is given a good account of modern technique in thoracoplasty, lobectomy and mediastinal operations. The section on abdominal surgery, consisting of nine chapters, is preceded by a valuable summary of abdominal incisions. Six chapters are devoted to genito-urinary surgery and are followed by one on the breast and another on gynaecology. The concluding part of the book is devoted to bones, the spine and the nervous and vascular systems.

We are convinced that the book is a valuable contribution on operative surgery. Much credit is due to the editor and his colleagues for presenting us with a volume 'which is not a textbook of anatomical exercises but a live surgery to help and refresh the practising surgeon'. The printing and get-up are excellent. A useful index is appended.

P. N. R.

TRAUMA AND INTERNAL DISEASE: A BASIS FOR MEDICAL AND LEGAL EVALUATION OF THE ETIOLOGY—PATHOLOGY—CLINICAL PROCESSES—FOLLOWING INJURY.—By F. W. Spicer, A.B., M.D., F.A.C.P. 1939. J. B. Lippincott Company, Philadelphia and London. Pp. xix plus 593, with 43 illustrations. Price, 35s. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta

AFTER what must have been an extensive search through the literature on the subject, Dr. Spicer has produced a book on trauma and its effects on the human organism. The types of trauma selected for discussion are those that are thought to act as agents in the production or aggravation of disease. The book therefore omits any account of minor injuries, fractures of the limbs and the like that are purely surgical in character.

The subject-matter is arranged in chapters dealing with trauma and the various organs, such as the brain, heart, respiratory system, abdominal viscera, and so on. Then there are chapters on trauma and its relation to conditions such as tuberculosis, neoplasms, fat embolism, and diabetes. Each subject is introduced by a classification of the types of injury to the particular organ and their effects. Illustrative case reports are given, and the chapter concludes with a summary and a list of references. Treatment is not discussed as it is outside the scope of the work.

It is an especially valuable treatise because it was written on a clinical basis, and wherever a particular subject threatens to become unwieldy the author has had recourse to tabulation. Thus, the reader may be surprised to find that no less than fifteen conditions following injury to the pancreas have been listed. There is a strong medico-legal flavour about many parts of the book, and practitioners who have to engage in this sort of work will find many sections that render practical help, notably those on trauma of the brain, on syphilis and tumours.

Although there is very little in the book which calls for revision, with the exception of figure 25 which has been printed upside down, the subject is new and therefore many other points are likely to be suggested for inclusion in a future edition. For instance, unpleasant sequelæ may occur to labourers working in retort houses or handling compressed gases and pneumatic machines; and the effects of inhalation of noxious gases are known to result in internal disease.

As it stands, however, the book is an important contribution to modern medical literature, and should achieve wide popularity.

W. McN. N.

SURGICAL PATHOLOGY OF THE DISEASES OF THE MOUTH AND JAWS.—By A. E. Hertzler, M.D. (Hertzler's Monographs on Surgical Pathology.) 1938. J. B. Lippincott Company, Philadelphia and London. Pp. xvi plus 248, with 206 illustrations. Price, 21s. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta

THE publication of the present volume completes a series of ten volumes or monographs by Dr. Hertzler on surgical pathology. The author deserves great credit for the successful termination of a difficult and arduous task. This volume consists of twelve chapters dealing with surgical diseases of the mouth, lips, tongue, larynx and jaws. The photographs and reproductions of histological sections are all excellent. This book has the distinction of being a monograph on a special subject, written by a general surgeon of ripe experience and rare courage. On the whole, it is written with robust common sense deserving of praise, but there are some statements which may call for criticism. Von Bergmann, it is stated, once said in his thunderous voice: 'There are but three common diseases in the mouth, tuberculosis, cancer and syphilis'. The author is at pains to point out that in his own district, 'the short grass country', both syphilis and tuberculosis are rarities; 'the rarity of the first being due to high moral standards, and of the other to the high general state of nutrition'. It may be remarked that this book is not dealing with conditions prevalent in the author's district only and it is quite possible that the same high standards do not prevail in other parts of his country.

The bibliography at the end of each chapter is fairly exhaustive but the author's remarks in the preface, needlessly provocative, are deserving of condemnation. 'It is difficult to collect a literature after a book has been written. . . . I have always held the idea that one has no right to quote literature which he had not read in the original. I have been sorely tempted, in this final round, to go into the market and buy citations at four cents a piece, the current rate. However, I have adopted the more respected practice of having my secretary copy them out of the Cumulative Index. Therefore, if the papers cited are not good, do not blame me, I have not read them.' Such arrogance is not found in a student of science and a seeker after truth. Admittedly it is not always possible to read foreign contributions in the original, but surely in the author's own country and language, there is available a literature of sufficient merit to command his interest and attention.

P. N. R.

THE PRINCIPLES AND PRACTICE OF OPHTHALMIC SURGERY.—By E. B. Spaeth, M.D. 1939. Henry Kimpton, London. Pp. 835. Illustrated with 413 engravings containing 1,031 figures and 4 coloured plates. Price, 45s.

NOWADAYS, in order to encompass the widening field, exhaustive treatises on surgical subjects are usually compilations by several contributors. However, this large textbook on ophthalmic operative surgery is, with the exception of one or two sections, the work of a single writer. But Dr. Spaeth has correlated the work of numerous surgeons throughout the world so successfully that his book has none of the disadvantages attending a 'one man show'. Much of his own work is presented, but it is all well worth reading and does not displace the prior claims of the work of others. In many instances he quotes *in extenso* from other authorities; the section on gonioscopy has been contributed by Dr. Otto Barkan, and that on corneal grafting by Dr. Ramon Castroviejo.

The book opens with a chapter on anaesthesia and operative and post-operative technique. Chapters then follow in a systematic manner, describing in turn the surgery of the orbit and lacrymal apparatus, the muscles, eyelids, the globe and its contents, and so on. The sections on the lids and ophthalmic plastic surgery appear to take a lion's share of the book, perhaps because the author's special interest lies therein. But

no section has been skimmed, so that an admirable balance has been preserved.

Numerous diagrams and photographs illustrate every section, though many, through considerations of space, have been so reduced as to become almost unintelligible. The extensive bibliography is, so far as we can verify, accurate, and readers in this country will be interested to find that much attention has been given to the work of surgeons in India.

We have no hesitation in recommending this book to ophthalmologists, and students working for the higher diplomas should certainly read it.

WORTH'S SQUINT OR THE BINOCULAR REFLEXES AND THE TREATMENT OF STRABISMUS. Seventh Edition by F. Bernard Chavasse, M.A., D.M. (Oxon.). 1939. Baillière, Tindall and Cox, London. Pp. xxii plus 688. Illustrated. Price, 25s.

It is gratifying to find that Worth's classical monograph was not allowed to become out of date when its original author was no longer able to undertake another revision. But after a lapse of ten years such great advances have been made in this subject that the new author, in part in collaboration with the late Mr. Worth himself, has found it expedient to rewrite the book entirely.

That Dr. Bernard Chavasse has achieved this brilliantly is at once apparent. The opening chapter is a conspectus of what is contained in the rest of the book; having first run through this, the reader is able to assimilate more easily what is undoubtedly a most difficult subject.

The first section deals with the anatomy, and the anatomical and reflex development in the child. This contains much new work, and throughout one is impressed with the knowledge that many of the old concepts on which we were brought up, and which are still being taught, must be abandoned. In fact the old ideas have been left so far behind that one wonders how much orthoptic work is being carried on on a basis of entirely wrong assumptions—but practitioners of the present methods of squint training must read the book and judge for themselves. The real significance of the exposure of the old clichés 'essential alternation', 'congenital defect of the fusion faculty', and so on, can hardly be appreciated by the general reviewer.

The last part of the book discusses in detail the treatment of squint according to the particular state encountered; the methods chiefly relied on are the use of glasses, occlusion, and operative correction.

Although the book contains nearly three times as many pages as the previous edition the subject is presented concisely, but nevertheless with a polished style that is a model of what medical writing should be.

W. McN. N.

A TREATISE ON THE SURGICAL TECHNIQUE OF OTO-RHINO-LARYNGOLOGY.—By G. Portmann. Translated by P. Viole, M.D. 1939. Baillière, Tindall and Cox, London. Pp. x plus 675, with 474 illustrations and 2 coloured plates. Price, 57s.

This is a translation of a book by a well-known continental surgeon in which he describes the procedures he employs in his clinics.

Each operation which is described is arranged according to a simple plan. The description is grouped under seven or eight headings, namely, indications, contra-indications, preparation of the patient, anaesthesia, instruments, technique, post-operative care, and sequelae. A telegraphic style is used, the actual operation is given step by step, and the whole is illustrated by a great number of large drawings together with photographs of the instruments arranged on the surgeon's and assistant's trays. This system makes for easy reading and rapid cross-reference, and has enabled the author to save space by avoiding much tedious repetition.

As the book is an account of Dr. Portmann's own operative methods and purposely describes only one

operation for each affection, criticism of operative technique seems out of place. On the contrary, there can be nothing but praise for what has been presented. But it is an incomplete work, if only for the reason that the whole field of peroral endoscopy is omitted.

It is a beautiful book, carefully printed and bound, but its price is beyond the means of the average student.

W. McN. N.

CLINICAL PATHOLOGY.—By P. N. Pantton, M.A., M.B., B.C. (Cantab.), and J. R. Marrack, D.S.O., M.A., M.D., B.C. (Cantab.). Fourth Edition. 1939. J. and A. Churchill, Limited, London. Pp. x plus 502, with 12 plates and 50 illustrations in the text. Price, 16s.

In the fourth edition of this well-known book on clinical pathology the various laboratory methods employed in the modern investigation of disease are fully described. The book is divided into nine sections, the first section dealing with the blood in health and disease, its chemical composition and the method of examination; the second section is devoted to parasitology and related subjects. In the third section is given an excellent account of the methods employed in the examination of 'puncture' fluids or fluids whether exudates, transudates or the contents of cysts as are commonly removed for examination by means of a needle and syringe. The next four sections deal with the examination of various 'systems' of the body. Then follows a brief account of the examination of sections of tissues and a useful summary of histological methods. The final chapter which is a new one in this edition deals with the pregnancy tests. The directions given for the various tests are concise and complete and clinical laboratory workers will find in this book much that will be of great help in the multifarious duties that such a laboratory has to undertake. This book will be specially of value to the advanced student of medicine, in understanding the various laboratory methods employed in the investigation of disease.

CLINICAL BACTERIOLOGY.—By F. A. Knott, M.D., M.R.C.P., D.P.H. 1939. J. and A. Churchill, Limited, London. Pp. viii plus 426, with 60 illustrations including 12 plates. Price, 12s. 6d.

THE most difficult problem that the medical teacher of to-day has to face is to decide on the scope of his lectures. It is easy enough for him to acquire very special and detailed knowledge on his own subject, but there are limits to the powers of assimilation of the student, who is studying half a dozen subjects at the same time. There are some excellent textbooks on bacteriology, e.g., Topley and Wilson's and Gay's, but these two books run to 1645 and 1581 large pages, respectively. It is out of the question to let the undergraduate student attempt to learn his bacteriology from such books and the bacteriological synopses are often unsatisfactory.

The present author has attempted to write a book that will give the student all the bacteriology he requires for the ordinary professional examinations and at the same time will help him in practice after qualifying. He can learn from it the methods of carrying out the simpler bacteriological procedures, and, what is far more important, the clinical application of the results of these. He will find up-to-date information on the tests it is worth while doing or recommending in various diseases, and on the interpretation of the reports that are sent to him. For example, there is a very good account of the antigenic structure of the enteric group of organisms with an explanation of the co-agglutinations that may occur and of the significance of H and O agglutinations.

One can unhesitatingly say that the author has succeeded. He has produced a book of moderate size which contains all that the student and the average practitioner need know on the subject and the information is as up to date as it can safely be.

CLINICAL BIOCHEMISTRY.—By Abraham Cantarow, M.D., and Max Trumper, Ph.D. Second Edition. 1939. W. B. Saunders Company, Philadelphia and London. Pp. 666. Price, 27s. 6d.

WE had the pleasure of reviewing the first edition of the book seven years ago. On account of the great amount of knowledge gained since, the text has been revised thoroughly. Some of the chapters have been entirely re-written and several additions such as the influence of some of the endocrine glands and vitamin B on carbohydrate metabolism, the biochemical aspects of vitamin deficiency, some of the aspects of mineral metabolism, etc., have been made. The change in the title of the book from 'Biochemistry in internal medicine' to 'Clinical Biochemistry' appears to us to be an improvement as the latter expresses the object of the book, *viz*, the application of biochemical observations in clinical medicine, more forcibly.

There can be no doubt that during the last few years biochemistry has made such rapid progress that it has now proved itself to be an important and powerful ally of clinical medicine, not only in the discovery of causes and cure of some important diseases, notably those of metabolism and nutrition, but also in the assessment of the prognosis in a given case. It also helps us considerably in the study of the functional efficiency of certain important organs and systems. The importance of the part which biochemistry plays in the practice of medicine is therefore undisputed.

The attempts of the authors in bridging the gulf between abstract biochemistry and clinical medicine deserve special praise and the clear, concise, and simple style of dealing with a highly scientific and technical subject is admirable and has made the reading of the book easy and enjoyable.

The book is up to date and deals with recent developments in the science of biochemistry in its relation and application to clinical medicine. The busy practitioner, who has no time to read elaborate textbooks or monographs, will profit considerably by the perusal of this book and will find that many of his conceptions of the biochemical changes in health and disease have undergone either radical changes or suffered considerable modifications. We have no hesitation in recommending the book to all who desire to have a clear understanding of the significance and limitations of laboratory investigations.

J. P. B.

OUTLINE OF ROENTGEN DIAGNOSIS: AN ORIENTATION IN THE BASIC PRINCIPLES OF DIAGNOSIS BY THE ROENTGEN METHOD.—By Leo G. Rigler, B.S., M.B., M.D. 1938. J. B. Lippincott Company, Philadelphia and London. Pp. vii plus 212, with 254 illustrations. Price, 30s. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 22-8

IN this book the author has collected his lecture notes revised and expanded to meet the demands of advanced instruction to graduates and radiologists. For this reason in the author's words 'it is in no sense a reference book, but rather a synopsis of a very extensive subject'.

The outstanding feature of the work is the collection in atlas form, with cross references in the text, of the 254 illustrations including a number of drawings by Jean E. Hirsch. The descriptions appended to these are sufficiently elaborate to admit of study independently of the text.

The unique drawings by Miss Hirsch are particularly worthy of study, although, in the reviewer's opinion, sketches and drawings of this nature can never replace good reproductions of actual skiagrams.

Owing to the method of presentation the accounts given of even some of the common diseases and procedures such as are connected with the introduction of iodized oil into the lungs and spinal canal, are

somewhat meagre. The section on the female generative organs also is very inadequate.

It is a work of considerable usefulness in that it adds to our collection of mental pictures of various conditions, but it cannot be described as a complete, or nearly complete, exposition of the subject, much less a *magnum opus*.

A word of congratulation is due to the publishers for the artistic manner in which skiagrams, sketches and drawings are reproduced.

PATHOLOGICAL TECHNIQUE: A PRACTICAL MANUAL FOR WORKERS IN PATHOLOGICAL HISTOLOGY INCLUDING DIRECTIONS FOR THE PERFORMANCE OF AUTOPSIES AND FOR MICROPHOTOGRAPHY.—By F. B. Mallory, A.M., M.D., S.D. 1938. W. B. Saunders Company, Philadelphia and London. Pp. 434. Illustrated. Price, 20s.

THIS is a book which will prove a most useful companion to practical work, whether in the laboratory, the post-mortem room or the museum. The technical methods that practical experience has shown to be of value are described. The book is divided into three parts, the first deals with general laboratory equipment and histological methods, the second with special histological methods and the investigation of miscellaneous infectious agents and the third part contains direction for the performance of autopsies. There are concluding chapters on photography and certain useful laboratory methods. Each section is dealt with in a practical way and the directions are given in such a manner that with persistence and experience any worker can get satisfactory results. The book can be confidently recommended to all students and workers of pathology.

PRACTICAL CHILD-PSYCHOTHERAPY.—By Curt Boenheim. 1938. John Bale Medical Publications, Limited, London. Pp. 177. Price, 10s. 8d.

THE value of this little book would be greatly enhanced had it been provided with an index. The absence of an index is all the more remarkable in view of its author being a German.

The author is to be congratulated on his cautious approach to a difficult and much disputed field of therapy. He is fully aware of the debt psychotherapists of every school owe to the pioneer work of Freud, Adler, Jung and Stekel. Most, indeed, of the authorities whom he quotes are non-British. The author warns his readers against accepting too hard-and-fast a concept of 'normality', particularly in children who are in a state of development so that what is normal in children to-day may be pathological to-morrow.

In his review of the psychotherapeutic methods at our disposal for the treatment of children, the author discusses the value of psycho-analysis, observing children at play, hypnosis, rest, relaxation and exercises. In dealing with the principal behaviour disorders in children, the author does not seem to lay much stress on 'conflict' as a basis of such types of disorder. He is more inclined to find the causes of psychic ailments in children to lie in their environment, particularly as regards the poverty of the home and the temperament of the parents. This outlook could only be definitely established after a comparative study of 'home' conditions among a much bigger range of family life, including, of course, the family life of primitive people. The author does well to emphasize the main difficulty in child-psychotherapy, namely, the psychopathy of the parents. No one who has practised child psychotherapy will deny that the main obstacle to successful treatment of children is the obstructive attitude of their parents which is moreover often very subtly expressed.

The author has some interesting observations on the part played by 'imitation' in childish ailments, particularly ailments involving circulatory and respiratory affections. The author's treatment of non-epileptic 'fits' in children is rather unsatisfactory. The subject is much more complicated than he would appear to

imagine. In spite of these and some other defects, a book on the psychotherapy of children should be welcomed by medical practitioners in this country where so much ignorance still exists on the subject.

AN INTRODUCTION TO DERMATOLOGY.—By Norman Walker, Kt., M.D., LL.D., F.R.C.P., and G. H. Percival, M.D., Ph.D., F.R.C.P. Tenth Edition. 1939. W. Green and Son, Limited, Edinburgh. Pp. xvii plus 391, with 102 plates and 96 illustrations in the text. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 14

This book has been one of the best known and most widely used small books on skin diseases for the past forty years, as the first edition appeared in 1899. It is remarkable in that the original author is still active in its production, though he is now assisted by a collaborator.

Although it may be still classed as an introduction to dermatology it is much larger than it was about thirty years ago when the reviewer first made its acquaintance. Many additions have been made as our knowledge of skin diseases has advanced, but re-classification in accordance with improved knowledge appears to have been ignored. For example, very nearly three hundred pages of the three hundred and eighty-one of text which the book contains occupy one section under the heading 'Inflammation'. It is true this is divided under sub-heads but, to take a haphazard selection from the contents pages, when one finds chilblains, lupus erythematosus, hydroa, pemphigus epidermolysis bullosa, and herpes following each other in that order it is rather confusing. It is also unusual at the present day to find verruca and molluscum contagiosum among the 'new growths'.

Apart from this comparative absence of grouping the book is an eminently practical production and is full of valuable tips, it is also unusually well furnished with well-produced colour plates for a book of its size, and it can be recommended to the general practitioner as his handbook on dermatology.

P. A. M.

COMPARATIVE STUDIES CONCERNING THE STRENGTHS OF ņSTROGENIC SUBSTANCES.—By Kaj Pedersen-Bjergaard. 1939. Oxford University Press, London, Humphrey Milford. Pp. 198. Illustrated. Price, 15s. Obtainable from Oxford University Press, Bombay and Calcutta

ALTHOUGH the introduction of the international ņstrone standard in 1933 removed the long-felt want of a constant unit of measurement for the biological determination of the activity of ņstrogenic substances, it was soon found that this standard preparation was not suitable for the comparative testing of all ņstrogenic substances, and hence, in 1936, another standard, 'The ņstradiol mono-benzoate standard' was introduced, in addition, as the unit of measurement for the biological determination of benzoylated ņstrogenic substances. This also was found to be not wholly satisfactory.

The present monograph, written for the purpose of elucidation of the problem of assaying the biological activities of the different ņstrogenic substances, appears to be a great step forward in the realm of sex hormones. The applicability of the international standard preparations as bases for comparison in the assay of other pure ņstrogenic substances and their esters, as well as of the mixtures of more or less purified ņstrogenic extracts has been tested in a series of experiments on various kinds of animals and with varying methods of administration.

The amount of laborious and painstaking experimental work which the author has incorporated in the monograph is amazing, and will no doubt make the work of future workers on the subject much easier. It is very comprehensive and illuminating and will be invaluable to those who are interested in this particular branch of endocrinology.

J. P. B.

MEDICINE FOR NURSES.—By W. Gordon Sears, M.D. (Lond.), M.R.C.P. (Lond.). Third Edition. 1939. Edward Arnold and Company, London. Pp. viii plus 447. Illustrated. Price, 8s. 6d.

This is an excellent book, and one that should prove very helpful for senior nurses studying for their final examination.

It is simply and clearly written, also well tabulated, covering all branches of medical nursing that the student nurse is expected to know.

C. F.

AEQUANIMITAS WITH OTHER ADDRESSES TO MEDICAL STUDENTS, NURSES AND PRACTITIONERS OF MEDICINE.—By Sir W. Osler, Bt., M.D., F.R.S. Reprinted from the Third Edition. Biographical Note by Sir W. Langdon-Brown, M.D. (Cantab.), F.R.C.P. 1939. H. K. Lewis and Company, Limited, London. Pp. xiv plus 451, with a portrait. Price, 7s. 6d.

THE detailed review is unnecessary of this classic, which has been in constant demand since its first appearance in 1904. The present edition has been reprinted in England from the third edition which appeared in America in 1932, and it marks the fourteenth actual reprinting of the book.

It contains twenty-two addresses delivered by Sir William Osler in America and Canada up to the year 1905 when he left the United States for Oxford. This edition has been enhanced by the inclusion of an excellent photograph and a short bibliographical note by Sir Walter Langdon-Brown on the author, which supplies an insight into the lovable character of this great man and helps one to understand how he was able to write such a collection of speeches all of which contain valuable advice for the medical student and young practitioner.

It is a book that every medical student should read and read again. In it at the end Sir William has given a list of ten books which he recommends as a bed-side library for medical students; this might very well be increased to eleven by the addition of *Aequanimitas*.

P. A. M.

SHORT NOTES ON LEPROSY.—By Dr. D. N. Mukherjee, M.B., B.S. (Lucknow), Leprosy Specialist to the Government of Central Provinces and Berar, Raipur. 1938. Published by the Author. Pp. 25. Price, As. 2 per copy

IN the limited space of this little booklet the author has tried to deal with all the different aspects of leprosy—classification, clinical manifestations, diagnosis, differential diagnosis, laboratory tests and control of leprosy. The description has naturally to be very brief. The type and paper used is quite good but there are several printing mistakes. The author makes no mention of the presence of thickened nerves as one of the cardinal points in diagnosis of the disease. The booklet is quite cheap at two annas and will be useful to health visitors employed in anti-leprosy work.

GROSS ANATOMY: A BRIEF SYSTEMATIC PRESENTATION OF THE MACROSCOPIC STRUCTURE OF THE HUMAN BODY.—By A. B. Howell. 1939. D. Appleton-Century Company (Incorporated), New York and London. Pp. vii plus 403. Illustrated. Price, 25s.

IN his introductory chapter, the author deplores the tendency of the average textbook to become a book of reference from which, nevertheless, the student tries to learn anatomy without the aid of the cadaver. On the other hand he indicts the dissecting manual because the student 'looks for what he is told to seek and tends to ignore other details, thus dulling resourcefulness and initiation (*sic*)'.

Though not wholeheartedly endorsing these views, it was with some interest that we turned to the subject-matter of the book, hoping that perhaps Professor Howell had produced some system that would

case the burden of the student who is about to embark on the study of anatomy. We were disappointed.

The book is arranged along formal lines, and much care has been devoted to the introduction of each section, in which the student is given a general survey of the anatomy to be described from the developmental and morphological aspects. But in several instances there has been so much deviation into the realms of embryology and comparative anatomy that most students will find themselves *rari nantes in gurgile vasto*.

The bulk of the book consists of detailed anatomical description on the lines of, but shorter than, that found in the standard textbooks. The explanation of the paucity of illustrations is to be found in the introduction, in which we read that the student is expected to have at hand 'any good atlas of anatomy'. No suggestion is made that he should also supplement his reading by a study of the living body, the cadaver, and the skeleton.

W. McN. N.

Abstracts from Reports

KASHMIR MEDICAL MISSION OF THE CHURCH MISSIONARY SOCIETY: REPORT FOR 1938

ALTHOUGH much progress has been made by the State in recent years in Kashmir, there is still much unalleviated sickness and suffering. The Mission Hospital is not the only medical institution in Kashmir. In Srinagar there is a State General Hospital and also two women's hospitals. There is also a tuberculosis sanatorium and a leper hospital. In most of the larger towns and villages there are dispensaries where patients can receive treatment and medicine. The large number, both of out-patients and of in-patients, that come to us year by year, is an indication of the high esteem in which this hospital is held by the people of Kashmir.

On the medical side, consumption is very rife. This year a special tuberculosis clinic has been held twice a week to deal with the large number of patients that come to us. A new form of injection treatment has been tried, but it is early yet to state how successful it is.

Several cases that have been operated upon this year for abdominal conditions have been proved at the operation to be malignant. We have had cases of cancer of the stomach, bowel, breast, mouth, eye and limbs.

Venereal disease is rampant in Kashmir. Patients usually come to hospital in the secondary or tertiary stages, and late manifestations are all too common. A venereal disease clinic is held twice weekly, and the routine treatment with blood tests is carried out. An interesting fact about syphilis in Kashmir is that it seldom affects the nervous system. Tabes dorsalis and general paresis are almost unknown. Indeed, nervous diseases of any kind are rare, although there has recently been a case of chorea, and a case of paralysis agitans in the hospital. Another interesting medical anomaly is that while rheumatic heart disease is exceedingly common, acute rheumatism is very rare. Neither is rheumatoid arthritis met with in Kashmir.

Typhoid is endemic and we usually have cases in hospital. It is seldom virulent and most cases recover. Dysentery is common and is usually amœbic, responding well to emetine treatment. This year there was a mild outbreak of cholera. It did not prove serious and there were only a few cases.

On the surgical side, osteomyelitis is by far the commonest disease. It affects the underfed and those exposed to manual work. It is more common in men and boys than in women and girls. The leg and thigh bones are more frequently affected than the bones of the arm or forearm. Most cases come to hospital in the chronic stage, and we usually perform an osteotomy or sequestrectomy. Tuberculosis affecting bones and joints is becoming increasingly common, and we are seldom without several cases of tuberculosis of the hip, knee or ankle in the wards.

A large number of abdominal operations have been performed. Appendicitis is fairly common, and so are gastric and duodenal ulcers. For the latter conditions we frequently perform gastro-enterostomy. Gall stones are not infrequent, and occur more commonly in women than in men. Stones of the bladder and kidney

are less common than in the hotter parts of India, but we have had several cases during the year. Hydatid cysts of the liver, intestinal obstruction, abdominal tuberculosis and ovarian cysts have contributed to our list of abdominal operations. Goitres, hernias, hydroceles and hæmorrhoids are all very common. Cataract and trichiasis are the commonest eye operations.

A word concerning the background of these patients. The majority of them live in squalor and poverty scarcely believable to those living at home. Their diet consists of rice, vegetables, milk and a little meat. In terms of calories the food value of this diet is very small—very much less than is theoretically required for a healthy person. Small wonder that they are undernourished and succumb so readily to disease, and small wonder that few live to reach an old age.

In this hospital we are trying to alleviate some of the sickness and suffering in Kashmir. There are many people who have been patients here, who are grateful to those who support this hospital, and make this work possible. We hope that all those who have so generously helped us in the past will still continue to do so in the future.

REPORT OF THE MEDICAL RESEARCH COUNCIL, LONDON, FOR THE YEAR 1937-1938. PUBLISHED BY HIS MAJESTY'S STATIONERY OFFICE, LONDON. PRICE, 3s. 6d. POSTAGE EXTRA

It is now twenty-five years since the Government decided to promote medical research by setting up the Medical Research Committee, which became the Medical Research Council in 1920. In this period there has been a great increase in medical investigations in Great Britain, some of which are undoubtedly due to the support provided by the State. In other countries there has been a similar acceleration in intensity of medical discovery, particularly in the United States of America, where it has been made possible mainly by private endowment. All this activity has brought about a great increase in knowledge of the body in health and disease—greater even than that of the previous twenty-five years, which in itself was large. Historians are likely to pronounce this period as outstanding in the improved level of health of civilized communities made possible by the access of knowledge won by medical research.

THE APPLICATION OF KNOWLEDGE IN TREATMENT

Apart from its effect in raising the standard of health and physique, this new knowledge has had two influences which, in their effect on medical practice, are often opposed to each other. It has resulted in the first place, in a great improvement in methods of diagnosis and treatment of disease. These discoveries, together with the development of the social conscience of the community in regard to the unhealthy individual, have involved a vast increase in medical services. The number of medical men, both in public and private practice, has increased greatly, hospital accommodation

and facilities have multiplied, and the total cost of medical care has risen enormously. The development of new methods of diagnosis and treatment has called for so much additional personnel and costly apparatus that it has become more and more necessary for the sick to enter public institutions in order to receive the full benefits now available. The radiographic department, the biochemical, the hematological and the bacteriological laboratories, which hardly existed twenty-five years ago, are now large and important factors in all efficiently run medical institutions. Hardly a patient enters such an institution whose condition does not call for the help of these newly grown hospital services.

While everyone will agree that all these changes have been justified and beneficial, there must often pass through the mind the question—what is to be the end of this development? Will medical science with its ever greater knowledge require hospitals and their scientific services to grow continuously; are there to be no limits to their size? The economist might even wonder whether a time will not come when the expense and trouble involved will hardly justify this extension of medical practice, especially that large part concerned with chronic and degenerative forms of disease and for which the practical return in terms of human health is often small.

This, of course, is only one aspect of the matter. The whole trend of medicine in the present century has been to study the basic etiological factors of individual diseases in order to find methods for curing them, and it is to the application of this side of medicine that the extended hospital services are mainly directed. A large number of diseases of which treatment at the beginning of the century was essentially concerned with the relief of symptoms and the comfort of patients—leaving the cure to the care of *vis medicatrix naturæ*—can now be cured or controlled by specific remedies and the sufferers returned to normal healthy existence. Many thousands of patients suffering from diseases which, twenty-five years ago, were incurable and uncontrollable, can now be restored to health as the result of recently acquired knowledge applicable to diagnosis and treatment.

Applications of chemotherapy.—It sometimes happens that new knowledge of curative treatment may in itself also bring about reduction in incidence of disease, as, for instance, in infectious diseases and those of a chronic nature. This will probably prove to be the case in some infectious diseases following the recent advances in treatment by sulphanilamide and allied substances. For example, the more rapid and effective cure of gonorrhœa by these drugs ought to result in a definite reduction in its incidence, not only because of their curative action but because they may reduce the spread of the infection.

Recent results give hope also that these drugs may lead to the reduction of one of the most common chronic disabilities, namely, middle ear disease, which often follows measles and scarlet fever or may be a sequel to a sore throat due to streptococcal infection. If the claims that it has a powerful destructive effect on the middle ear can be proved to be true, it ought to have a powerful curative effect to those cases of middle ear disease which are due to this organism. How enormous such preventive effects might prove can be estimated from the fact that there are said to be 2,500,000 people in this country with disabling degrees of deafness, and that disease of the middle ear is admittedly responsible for a large proportion of these cases. Thus it has been estimated that this condition is responsible for 90 per cent of all cases of acquired incomplete deafness in children. It is obvious that optimum results along these lines will be obtained only by medical skill alert to the development of the condition, especially in young children, and to the need for immediate treatment by the chemotherapeutic agents now available. A good opportunity may well be at hand for seriously attacking middle ear disease and reducing greatly this widespread and serious disability and its sequelæ, running ears and deafness.

APPLICATION OF KNOWLEDGE IN PREVENTIVE MEDICINE

On the other hand, medical research has brought another kind of knowledge which, if properly used, leads directly to the prevention and elimination of disease. The effect on medical practice and its ancillary services of this kind of knowledge is clearly opposed to the first-mentioned effect since, by eliminating disease, it tends to reduce the needs for curative aids.

In view of the large increase in hospital services and medical personnel in recent times, it might be thought that the results and effects of research in preventive medicine must be negligible. This is not, or ought not to be, the case; but undoubtedly there is often great delay in bringing about the application of new discoveries to preventive ends. Fresh means of curative treatment, on the other hand, are generally applied at once by medical practitioners, and the latent period between such discoveries and their application is often short.

Everybody will agree that, of the two types of knowledge, that which leads to the eradication of disease is much the more important to the community. Why then should there be great delay in its application? No simple answer can be given to this question. Prophylaxis against disease does not depend solely on the alertness of medical men or of Government departments to procure rapid application of new knowledge. Just as important is enlightenment of the public as to the merits of a particular discovery, since these applications of medical science often require direct action on the part of individuals. The public, however, cannot understand the merits of such very technical subjects unless they are clearly expounded and the meaning of the results driven home. Again, successful cure of disease is always dramatic, and brings with it intense relief both to patients and their friends. There is, however, nothing dramatic about the disappearance of disease. It is here to-day and gone to-morrow, and the very success of prevention of disease is measured by forgetfulness. Whoever thinks nowadays of the decimation once caused in this country by plague, cholera, typhus and other diseases now eliminated from our midst? The relative lack of dramatic interest in the prevention of disease, as compared with that in its cure, is partly responsible for the difference in rates with which their advantages are obtained by the public. A third cause of delay is the fact that preventive medicine mostly concerns children, and it is curious that illness and death in the young do not, apparently, impress themselves on the public mind with the emphasis associated with disease in the adult.

It is becoming every day more clear that these difficulties in matters of health and disease, especially when the co-operation of the public is necessary, will remain so long as there is no means of educating and giving them the requisite guidance. It does not seem to be anybody's business in this country to undertake this task. Only too often are the public dependent for information and guidance on advertising propaganda, and as it so often is, financed by those who sell. Others who are most assiduous in those who believe that advances in medicine, especially when of great practical value, are snares and delusions, and who by extensive propaganda mislead in every conceivable way and hinder the process of application.

It is not the duty of the Medical Research Council to guide the public on the importance of medical discovery in its practical applications to human needs. Their task is wholly to promote discovery and to announce it to the world when it is made. They cannot but view with regret, however, the delay which so often occurs between medical discovery and its application, especially when the discovery is one that provides an immediate opportunity of preventing or even eliminating disease. What the ultimate solution of this difficulty will be is not obvious, but with the present increase in knowledge of methods of preventing disease, a better method of informing and educating the public becomes imperative.

The prevention of diphtheria.—One of the most striking instances of the delay in the application of new knowledge is the relative lack of public recognition, in Great Britain at the present time, of the existence of a method of proven value for the prevention of diphtheria. Diphtheria is the commonest single cause of death among school children. In 1937, there were 61,339 cases of this disease in England and Wales, causing 2,963 deaths, nearly all in children between the ages of 1 and 15 years. This is pure tragedy, in view of the needlessness of such deaths, for since 1929 prophylactic inoculation against diphtheria has proved increasingly successful wherever it has been properly used.

The value of improved nutrition.—A second type of preventive measure against disease, of which the proper application has now been delayed for many years, is to be found in improved nutrition. The need for this has been often discussed in previous Annual Reports of the Council; but the adoption of modern teachings on the subject by the public is depressingly slow, in spite of the evidence often advanced that the increased consumption of protective foods would not only be beneficial to the physique and general health of the people but also of great economic value to the country.

Better feeding in infancy has caused a gratifying reduction in rickets throughout the country, although the time has not yet arrived when an incident would be possible here such as recently occurred at the Children's Hospital at Toronto, where a case of rickets created such surprise that a meeting of staff and students was summoned to examine the baby. There is still room for great improvement in this respect, for, with the knowledge and public assistance available, the persistence of rickets in this country is an indication of ignorance or neglect. It is of interest to recall that an attack on the problem of rickets was included in the first research programme of the original Medical Research Committee in 1914, and that it is owing to the results of this work that the disease can now be prevented.

A much greater consumption of milk, and other dairy products, of eggs, of vegetables, including potatoes, of fruit, and of fat fish, at the expense of bread, biscuits, sugar and sweets, especially in early life, is an urgent national requirement; it will not only improve the physique of the people but will reduce the amount of dental decay and greatly raise the standard of health. An increase in breast-feeding will still further reduce the high mortality rate of infants from gastro-intestinal troubles and bronchio-pneumonia. Whatever advances in medical knowledge may come, until these simple precepts are adopted there will still remain a great deal of preventable disease in this country.

The co-operation of the public.—These few instances will probably suffice to emphasize the possibilities of applying the results of medical research to immediate problems of preventive medicine. It is clear that some of the methods for preventing disease require close co-operation on the part of an enlightened public. There is great need for some authoritative body to transmit the necessary information which will stimulate public co-operation. With a more rapid understanding of the facts on the part of the public, delay in application of new knowledge to human needs ought not to be so long as it has been in the past. Only by improving the general health and eliminating disease can it be hoped to reduce this present tendency of ever-increasing medical services, and the annual expenditure of between two and three hundred million pounds which such services necessitate.

RESEARCH POLICY

While the Medical Research Council must necessarily be interested in the general problem of the practical application of new knowledge, they are more directly concerned with the question of the best methods of promoting the research work itself. The over-riding consideration must obviously be the acquisition of knowledge which will make possible improvement in the standard of mental and physical health, and the prevention, alleviation and cure of disease. It is by no means

certain, however, by what policy such knowledge may be most quickly and effectively obtained. Some think it is to be done by directing attention to disease itself, and others by promoting fundamental studies of the physiology and chemistry of the body. These views need not be discussed further, because it cannot be doubted that knowledge of practical significance in matters of health and disease can come from any direction. The work of Pasteur on fermentation led to the work of Lister on prevention of wound infection. On the other hand, the discovery of Eijkman of the cause of beri-beri led ultimately to more academic researches on the part played by vitamin B₁ in the oxidation of carbohydrate. Experience has shown that experimental work from any quarter may lead to the solution of problems from any other quarter.

The question may then be asked, what is the policy of the Council in promoting research? Do they initiate research, and, if so, in what way; or do they leave to individuals the choice of subject and support it if satisfactory? Do they favour research on disease itself rather than on more academic problems of physiology and biochemistry? A complete answer to these questions cannot be given here, but the general situation stands as follows. Actual promotion of specific research by the Council is usually done by appointment of individuals to their permanent staff. This choice depends on the subject which seems to require special attention and the merits of the person chosen. When once appointed the individual has wide liberty of action in planning investigation. The Council seldom choose particular diseases for investigation; generally, the choice is of a broader nature, so as to include study of an aetiological factor common to a group of diseases, or a type of treatment of wide application, or a system of physiological or biochemical control.

Examples of such broad subjects of investigation at the present time are virus diseases, endocrinology, and chemotherapy. In each of these cases groups of workers have been appointed to follow lines of investigation in their own province and they are expected to be familiar with, and prepared to help, researches cognate to their own throughout the country. If suitable opportunity offers itself, investigations by other workers in the same fields are also assisted by the Council. By this means co-ordination of effort throughout the country is brought about.

For another large part of the work, helped by the Council by means of personnel and expenses grants, the initiative in choice of subject and method of investigation lies with the head of a laboratory or hospital in respect of some individual worker, or with the worker himself. The success of the application depends upon the merits of the individual and the subject of research. The Council do not provide money for institutions but for individuals, because they regard it as essential that they should retain direct control over the choice of the worker and the type of investigation proposed.

As to whether the Council encourage the direct study of disease or of the more fundamental sciences, the general answer is that they welcome both kinds of investigation. At the same time they recognize that at present there is a relatively great dearth of work in clinical science and in experimental pathology in this country, as compared with many other branches of medical science. So impressed indeed are they by this state of affairs that they are making special efforts to enlarge the available personnel by offering scholarships and fellowships to enable young men and women to enter these particular fields of inquiry. In addition, they have set up special posts, and they are prepared, as opportunity offers, to establish more units for clinical investigation.

So far, then, as initiation of medical research is concerned, the Council's objectives are mainly of long distant and comprehensive type. They send fleets out in several directions and in different seas, hoping that individuals will seize any special prize of discovery that shows itself in any quarter. In the course of such research any good opportunity that offers itself in the form of an *ad hoc* problem is taken, and work may

thus be expressly directed to the solution of specific questions.

TROPICAL MEDICAL RESEARCH IN THE COLONIAL EMPIRE

This activity of the Council was discussed at length in the Annual Report for 1935-36. It resulted from the desire of the Colonial Office that the Council should extend their research interests to problems of tropical medicine, and no invitation has been accepted with greater pleasure. It clearly offered opportunities for discovery, almost unequalled in any other field. On the one hand, any discoveries made would almost certainly be of great practical consequence and might assist in raising the standard of health in countries for which Great Britain has a special duty and responsibility; on the other hand, some diseases in the tropics, such as pneumonia and tuberculosis, are also common in this country, and there was the probability that the simpler conditions of life might allow easier investigation than here.

One of the difficulties to be overcome in accepting this request was the dearth of investigators trained to study tropical diseases, and, as previously explained, the Council devised a scheme of junior and senior fellowships to encourage promising young workers to enter this field and undergo special education and training. In the three years since the scheme was initiated, eight junior and three senior fellowships have been awarded. Fully trained investigators have been sent to the Gambia, Uganda and Tanganyika Territory, to study the action of chemotherapeutic drugs on sleeping sickness, the natural history of yaws, and other problems.

NUTRITIONAL PROBLEMS IN THE COLONIES

In the past year a different kind of opportunity arose for assisting the Colonial Office, as the result of the world-wide interest in nutritional problems. In 1936 the Secretary of State for the Colonies sent out a circular despatch drawing the attention of Governors of colonial territories within the Empire to modern aspects of nutrition and their relation to health, and asking for their comments and advice on such matters as they affected each territory. The response was surprisingly great and resulted in the setting up of an Advisory Committee on Nutrition in the Colonial Empire upon which the Medical Research Council were represented. Many of the replies received from Governors of colonial territories, while showing the greatest interest in the subject and realization of its importance, also made it clear that much more information of the actual dietetic and nutritional problems to be faced in each territory was needed, and that this information could be obtained only by further investigation. To meet this situation, the Advisory Committee on Nutrition set up a sub-committee, with Sir Edward Mellanby as Chairman, to prepare a co-ordinated plan of field surveys and research which might with advantage be carried out with regard to nutrition in the Colonial Empire.

After reviewing the situation, the sub-committee made the recommendation to the Secretary of State for the Colonies that the Medical Research Council should be asked to appoint, for a period of five years in the first instance, a small staff whose duty would be to undertake the scientific co-ordination of a series of field surveys of diet in relation to health and physique in the colonial territories. It was also recommended that the actual field surveys should be made by officers seconded from the colonial service in each territory concerned, and that the main duty of the staff appointed by the Council should be to co-ordinate the inquiries, to ensure the adoption of comparable methods and standards in the different territories and the uniform interpretation of the complete results. These suggestions were approved by the Secretary of State, and the Council willingly agreed to accept the responsibility entrusted to them. It was arranged that the salaries of the staff appointed by the Council for co-ordinating the programme of work should be paid by the Council, while other expenses should be borne by the Colonial Development Fund.

[This closely printed volume of over 200 pages is so packed with information on the innumerable activities of the Medical Research Council that it is quite impossible to give an adequate review of the matter it contains, in the space at our disposal; even a bare list of the researches would take up almost too much room. We therefore have been compelled to abstract freely from the introduction to the report, and strongly recommend all medical research workers to consult the original.—EDITOR, I. M. G.]

ANNUAL REPORTS AND STATISTICS OF THE GOVERNMENT GENERAL HOSPITAL AND THE BARNARD INSTITUTE OF RADIOLOGY, MADRAS, FOR THE YEAR 1937

CLINICAL REPORT BY LIEUT.-COL. G. R. McROBERT, I.M.S.

DURING the year ten cases of chronic endemic fluorine intoxication were admitted from Nellore district and the clinical findings were incorporated in a paper published in the *Indian Journal of Medical Research*.

Problems in anaemia engaged much of the time of the staff, and researches were conducted on the occurrence of achlorhydria in both megalocytic and microcytic forms of anaemia. Achlorhydria with lack of histamine response was found in cases of pure microcytic anaemia as well as in the megalocytic forms.

Koilonychia was noted in microcytic achlorhydric cases even in males (Witt's anaemia).

The great value of iron in the treatment of microcytic anaemia, even in the presence of large numbers of ankylostomes and of achlorhydria, was demonstrated to successive batches of students.

Megalocytic anaemia in both male and female with all the laboratory findings commonly present in Addisonian pernicious anaemia (achylia gastrica with no histamine response, positive indirect van den Bergh reaction) were treated successfully with marmite and iron, and no case which failed to respond to marmite and iron subsequently responded to liver.

In the past three years no case of true pernicious anaemia has been found.

A small investigation on the effect of anaemia on the size of the heart was carried out, and the great dilatation of the heart in severe ankylostome anaemia, with prompt improvement with iron administration, was demonstrated.

CLINICAL REPORT BY DR. P. S. VARADARAJAN

The subject of filariasis as approached by the clinician appears to present some very interesting facts, such as—

(a) The symptoms are not merely confined to the obstructive phenomena nor even to the hypothetical streptococci, thought to play an important rôle in the symptomatology of the disease. On the other hand, the protean nature of the signs and symptoms lead one to look for the cause elsewhere.

The possibility of the extrusion of a toxin attributable to the microfilaria either in its genesis or in its lysis has to be considered, as some of the symptoms appear to be allergic in nature.

(b) The disease appears to be very much on the increase.

(c) Elephantoid conditions are getting rarer.

A select group of cases of myocarditis that have eluded classification was studied.

As there has been no reference to this type of cases in any of the available medical literature, a brief description is permissible. The basis of these cases is certainly nutritional, but the deficiency which is mainly exogenous produces a clinical picture quite unlike that of beri-beri. The central theme is that of a gradually deteriorating myocardium as evinced by the functional deterioration of the heart to the exclusion of any involvement of the other systems. The cases present the symptoms of a non-congestive left ventricular failure and congestive failure is significantly absent at least in the early stages. The artisan rather than the labourer is afflicted. Poor food (in caloric value) is more often the cause than too little food.

Correspondence

TWO CASES OF P. U. O. IN CHILDREN

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—I had two cases of P. U. O. in children this summer. One child is one year four months old and another child is four months old. Both children ran an irregular temperature. The temperature in the axilla would be between 99 to 100.4. The pyrexial period lasts a day or two followed again by an apyrexial period of a day or two. Constipation was corrected by regular administration of hydrargyrum cum creta and pulvis rhei co. powders. Quinine had no effect in controlling the temperature. I could not examine their urines for, in spite of the best efforts of the parents, urines could not be saved for the examination; but a course of hexamine to sterilize the children's urine had no effect on the pyrexia. No worms were passed after santonin treatment. Typhoid fever was a possibility, but it was said to be so rare below 5 years of age. I could not do blood tests to eliminate typhoid and paratyphoid fevers. Clinically the children did not show any definite symptoms of these enteric fevers.

The interest in these two cases lies in the fact that the onset of fever corresponds with the hottest part of the summer (Hyderabad), and the fever had gone down as the days became less and less hot, and completely at the onset of rains. Hyderabad had rains on the 5th, and from 1st June the days are less hot than before. The older child was under my treatment from 13th May to 1st June, and the younger child from 16th May to 3rd June.

It is known that the thermogenetic centre in children is unstable; and so it is possible that the irregular low pyrexia in the two children reported may be due to the disturbances of thermogenetic centre from the external heat in the summer. Once the external atmosphere has cooled down, the children got better since the centres have regained their balance.

Yours, etc.,

S. VENKATESWARA RAO,
M.B., B.S. (Andhra).

THE EPIDEMIOLOGY OF CHOLERA

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—In the research section of the last annual report of the All-India Institute of Hygiene and Public Health, a method of forecasting cholera epidemics is referred to which depends on working out the regression equations connecting the mortality in certain weeks of the year with the total mortality of the preceding year.

The method is stated to be accurate for endemic areas.

The Asansol Mining Settlement, Bengal, is such an endemic area.

In this connection I desire to draw attention to the strikingly constant relation which appears to exist in the Asansol Mining Settlement between the number of deaths from cholera during certain weeks of the year (if the disease is not at the time generally epidemic in the province of Bengal) and the total number of deaths from cholera in the mining settlement during the same year.

From the accompanying table extracted from the Annual Reports of the Asansol Mines Board of Health for the years 1918-28, it will be seen that the mortality from cholera in the mining settlement during the month of March in any year in which the disease is not epidemic throughout the province very constantly

amounts to one-thirteenth of the total annual mortality.

As will be seen from the table, in years such as 1919, 1924 and 1926, when cholera was epidemic throughout the province, the proportion of the March mortality to the total annual mortality in the mining settlement was considerably greater than this, rising to one-eighth (and in 1919 to almost one-fifth) of the total annual mortality. The exceptionally low ratio (1:25) of the March mortality to the total annual mortality in the year 1921, will be seen from a study of the annual report of that year to have been due to the numerous deaths in the month of May of cholera-infected tea-garden coolies on their way homewards through the mining settlement from Assam.

As this very constant and striking relationship exists in the Asansol Mining Settlement between the March and total annual mortalities from cholera, a similar relationship will doubtless be found, on careful investigation, to exist also in other endemic areas between the total annual mortality from cholera and that of some particular period of the year. It is to be noted, however, that the great majority of cases of cholera in the Asansol Mining Settlement for the period under review (with the exception of the year 1921) are stated to have been autochthonous and not due to contact. The cause of this relationship is obscure, but the phenomenon would appear to be a 'vital' one, and not merely coincidental.

TABLE

Year	Number of deaths from cholera during the month of March	Total number of deaths from cholera during the year	Ratio of figures in column A to those in column B
	A	B	
1918	18	225	1:13
1919	346	1,901	1:5.5
1920	13	170	1:13
1921	25	617	1:25
1922	15	169	1:11
1923	14	183	1:13
1924	41	317	1:8
1925	7	89	1:13
1926	74	570	1:8
1927	9	120	1:13
1928	8	105	1:13

Yours, etc.,

J. WALKER TOMB, O.B.E.,
M.D., D.P.H.

C/O STANDARD BANK OF
SOUTH AFRICA,
CAPE TOWN,
9th May, 1939.

[Note.—The period on which the whole argument is based is too small to allow definite conclusions, and, since data should be available for the last 10 years, there is no justification for omitting these. All one can say is that a *prima facie* case has been made out which may or may not prove to be true.

A point for consideration is whether the facts presented here are of any practical importance. If there was an even distribution throughout the year, 1/12th of the cases would occur in March; this is not very different from 1/13th. Do happenings in March give us warning of coming events more than do those of other months? Are these warnings obtained sufficiently early to be of practical value? These are the questions in whose answers the Public Health administration would be interested. No attempt has been made to answer these questions.—EDITOR, I. M. G.]

ANOMALIES IN THE MORPHOLOGY OF *P. VIVAX*

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—The article by Dr. B. M. Das Gupta, published in your May number, described abnormal forms of *P. vivax* in a new-born child, recalls a case we have recently seen in which similar abnormal parasites were found under somewhat similar circumstances. The occurrence is perhaps sufficiently unusual to justify a short note of the clinical and parasitological details.

An Indian child born on a malarious plantation in Selangor, one of the Federated Malay States, developed malaria on 5th March, 1939, sixteen days after birth. The mother had had *P. vivax* malaria two months before the birth of the child but had not had fever during delivery. There was active mosquito transmission on the plantation at the time and it is not unlikely that the infection was acquired after birth. Thin films sent to this laboratory by the courtesy of Dr. J. F. Mitchell, the estate medical officer, showed a malarial infection with a parasite generally resembling *P. vivax* but with differences from the normal morphology which were almost identical with those described by Das Gupta.

The infection was very heavy—more than 1,000 parasites per 100 leucocytes—and all stages of asexual development were present. The infected cells were heavily stippled with typical Schüffner's dots and normally enlarged. Many of them were fimbriated in the manner described by Das Gupta (plate X, figures 7 and 9). The ring forms were of normal appearance but there was a marked tendency to multiple infection of cells. The incidence of single to double and triple infection in 250 infected cells counted was 100 : 25 : 6; the incidence in normal *P. vivax* infection of similar severity, chosen at random, was 100 : 2 : 0. Three parasites in a single cell were seen in several fields containing no other ring forms. The most striking variation, however, from the usual morphology of *P. vivax* was the small size of the mature schizonts and the reduced number of merozoites. Most of the fully-segmented parasites occupied no more than about 2/3rds of the host cell, though a few were of normal size. The merozoite count in 100 schizonts apparently fully-segmented is tabulated below and compared with that from a normal *P. vivax* infection taken at random.

Number of merozoites	Schizonts (present case)	Schizonts (<i>P. vivax</i>)
6	3	0
7	2	0
8	10	0
9	15	0
10	21	0
11	16	0
12	15	4
13	10	3
14	5	14
15	3	15
16	0	30
17	0	13
18	0	12
19	0	5
20	0	3
20 +	0	1
TOTAL	100	100

It will be seen that in the case described the usual number of merozoites was from 8 to 13 and in the *P. vivax* control from 14 to 18.

The gametocytes were indistinguishable in size and appearance from those of *P. vivax*.

There was a recurrence of fever, and parasites were again found in the blood, on 15th June, 1939, three

months later. There were now present only young trophozoites and gametocytes which could not be distinguished from *P. vivax*. No schizonts could be found and, as early quinine treatment was essential on clinical grounds, there was little chance of ascertaining whether the abnormal forms found in the primary attack had reverted to type.

This case clearly has a close clinical and parasitological resemblance to that recorded by Das Gupta. In both cases the infection was heavy and occurred soon after birth. The morphological deviation of the two parasites from normal *P. vivax* was the same. The suggestion arises that this deviation may possibly be related to the growth of the parasite in an infant host.

There is intense *P. vivax* malaria on the plantation from which this child acquired the infection and it may be possible in the future to get further evidence on this point.

Yours, etc.,
JOHN W. FIELD,
and

J. C. NIVEN,
Malaria Research Division,
Institute for Medical Research,
Federated Malay States.

KUALA LUMPUR,
5th July, 1939.

Service Notes

APPOINTMENTS AND TRANSFERS

COLONEL W. E. R. WILLIAMS, O.B.E., to be K. H. S. Dated 17th December, 1938.

Colonel A. C. Munro to be V. H. S. Dated 15th May, 1939.

Colonel D. F. Murphy, M.C., to be A. D. M. S., Deccan District. Dated 21st June, 1939.

Colonel C. A. Wood, M.C., to be A. D. M. S., Kohat District. Dated 21st June, 1939.

Lieutenant-Colonel H. S. G. Haji, M.C., to be O. C., I. M. H., Secunderabad. Dated 21st June, 1939.

Lieutenant-Colonel D. R. Thapar to be O. C., No. 1 Coy., I. H. C., Rawalpindi. Dated 15th June, 1939.

Lieutenant-Colonel V. N. Agate to be O. C., I. M. H., Lahore. Dated 15th June, 1939.

On completion of his training at the Chemical Warfare School, India, Belgaum, Lieutenant-Colonel D. R. Thomas, O.B.E., resumed charge of the office of Chemical Examiner to Government of the Punjab on the 15th June, 1939.

Lieutenant-Colonel S. C. Alagappan to act as District Medical Officer, East Godavari, and Superintendent, Government Headquarters Hospital, Cocanada, with effect from the date of taking charge.

Major J. A. W. Ebdon, Principal and Professor of Surgery, Medical College, and Specialist in Surgery, King George Hospital, Vizagapatam, is appointed Chief Medical Officer and Civil Surgeon, Delhi, with effect from the forenoon of 22nd May, 1939.

Major G. F. Taylor, Professor of Clinical Medicine, K. E. Medical College, Lahore, has been appointed to officiate as Civil Surgeon, Lahore, in addition to his own duties, with effect from the 9th June, 1939, *vice* Lieutenant-Colonel W. Ross-Stewart, C.I.E., proceeded on leave.

Major T. C. Ramchandani to be Specialist in Surgery, Bombay. Dated 12th June, 1939.

Major Assa Singh joined the I. M. H., Lucknow, for duty, on transfer from the Medical Store Depot, Calcutta, on 24th June, 1939.

Captain M. Sendak is appointed as Senior Medical Officer, Port Blair, with effect from the date on which he assumes charge of his duties from Major B. Chaudhuri.

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the undermentioned officers of the Indian Medical Service with effect from the 1st April, 1937. These officers will count their seniority in civil employment with effect from the dates noted against their names, being the dates on which they joined civil employment:—

Lieutenant-Colonel S. C. Alagappan. Dated 20th February, 1937.

Major F. M. Collins. Dated 30th October, 1934.

Major P. V. Karamchandani. Dated 29th September, 1936.

Major S. T. Davies. Dated 7th December, 1936.

Major Lakshman Dass. Dated 30th January, 1937.

Major E. M. Sewell. Dated 28th October, 1937.

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the following officers of the Indian Medical Service with effect from the dates stated against their names:—

Captain J. S. McMillan. Dated 15th November, 1934.

Captain R. L. Haviland Minchin. Dated 30th April, 1936.

Captain F. A. B. Sheppard. Dated 3rd September, 1936.

Captain J. Edis-Myers. Dated 1st July, 1937.

Captain W. Happer. Dated 24th December, 1937.

Captain D. W. Taylor was transferred to civil employment in the Punjab. Dated 1st June, 1939.

Captain D. W. Taylor on completion of special duty at the Mayo Hospital, Lahore, assumed charge of the Office of Civil Surgeon, Sargodha, in June 1939.

Captain T. Sommerville was transferred to civil employment to the Pasteur Institute of South India, Coonoor. Dated 1st June, 1939.

Captain H. B. Wright has been granted a permanent commission in the I. M. S. from 7th June, 1939.

His Excellency the Governor of Bengal is pleased to appoint Captain P. I. Franks to be Surgeon on His Excellency's personal staff, with effect from the 12th June, 1939.

Captain J. W. D. Goodall made over charge of the Midnapore Central Jail to Major S. Annaswami, on the forenoon of the 20th June, 1939.

Captain S. P. Bhatia took over charge of the Medical Store Depôt, Calcutta, on 20th June, 1939.

The undermentioned appointments have been made:—

To be Captains (on probation)

Amarendra Krishna Dev. Dated 31st May, 1939, with seniority from 31st May, 1935.

Mohammad Akram. Dated 2nd June, 1939, with seniority from 2nd June, 1935.

Datla Satyanarayana Raju. Dated 4th June, 1939, with seniority from 4th June, 1935.

Monohar Singh Chadha. Dated 19th June, 1939, with seniority from 19th June, 1935.

To be Lieutenants (on probation)

1st May, 1939

Sydney George Nardoll, with seniority, 1st November, 1937.

Kenneth Donaldson Fraser, with seniority, 1st November, 1937.

Derek Hadroll Harrison, with seniority, 1st November, 1937.

William Daniel Pierson Griggs, with seniority, 1st May, 1938.

Gerald Samuel Michelson, with seniority, 1st May, 1938.

Walter McIville McCutcheon, with seniority, 1st May, 1938.

John Aitken, with seniority, 1st May, 1938.

Pierce Kent, with seniority, 1st May, 1938.

Richard Olyffe Yerbury, with seniority, 1st May, 1938.

Douglas Spencer Wilson, with seniority, 1st November, 1938.

The undermentioned officers are restored to the Establishment, 1st May, 1939:—

Lieutenant (on probation) J. P. O'Riordan, with seniority, 1st May, 1938.

Lieutenant (on probation) P. J. Wormald.

The undermentioned officers, on the grant of short service commissions in the I. M. S., reported for preliminary training on the dates and at the hospitals noted opposite their names:—

Lieutenant B. K. Kapur, Rawalpindi Hospital. Dated 22nd June, 1939.

Lieutenant P. C. Dhanda, Rawalpindi Hospital. Dated 6th June, 1939.

Lieutenant H. R. Pasricha, Rawalpindi Hospital. Dated 6th June, 1939.

Lieutenant M. Sarwar, Rawalpindi Hospital. Dated 22nd June, 1939.

Lieutenant M. S. Haque, Rawalpindi Hospital. Dated 24th June, 1939.

Lieutenant P. T. Joseph, Lucknow Hospital. Dated 22nd June, 1939.

Lieutenant K. K. Menon, Lucknow Hospital. Dated 22nd June, 1939.

Lieutenant N. Chakravarti, Lucknow Hospital. Dated 22nd June, 1939.

Lieutenant S. N. Chatterjee, Lucknow Hospital. Dated 22nd June, 1939.

Lieutenant D. K. Bose, Lucknow Hospital. Dated 22nd June, 1939.

Releases

Captain B. S. Bindra. Dated 16th June, 1939.

Captain W. A. Mirza. Dated 21st June, 1939.

LEAVE

In modification of previous notification, Lieutenant-Colonel A. D. Loganadan is granted combined leave for 12 months, with effect from the 6th December, 1938.

Lieutenant-Colonel B. Z. Shah, Civil Surgeon, Belgaum, has been granted leave on average pay for 4 months followed by leave on half-average pay for 6 months and 16 days preparatory to retirement, with effect from the forenoon of 20th May, 1939.

Lieutenant-Colonel G. A. Hildreth, O. C., Post Hospital, Dacca, proceeded on 12 months' combined leave *ex-India*, pending retirement, from 1st June, 1939.

Lieutenant-Colonel F. Phelan, O. C., I. M. H., Poona, proceeded on 3 months' combined leave *ex-India* from 3rd June, 1939.

Lieutenant-Colonel W. Ross-Stewart, C.I.E., Civil Surgeon, Lahore, proceeded on leave for 4 months, with effect from the 9th June, 1939.

Lieutenant-Colonel T. S. Shastri, Acting District Medical Officer, Kistna, is granted 12 months' leave, with effect from the 19th June, 1939, or date of relief whichever is later.

Lieutenant-Colonel A. H. Harty, Civil Surgeon and Superintendent, B. J. Medical School, and Mental Hospital, Ahmedabad, has been granted leave *ex-India* on average pay for 2 months and 28 days combined with leave on half-average pay for 1 month and 3 days, with effect from 6th July, 1939.

Major H. T. McWilliams, Staff Captain (Medical), Western Independent District, proceeded on 4 months' combined leave *ex-India*, with effect from 29th May, 1939.

PROMOTIONS

Majors to be Lieutenant-Colonels

S. D. S. Greval. Dated 12th May, 1939.

G. H. Fraser. Dated 25th May, 1939.

Lieutenants (on probation) to be Captains (on probation)

L. E. Elkerton. Dated 28th April, 1939, with seniority from 1st January, 1939.

C. C. Harvey. Dated 24th May, 1939, with seniority from 1st July, 1938.

D. F. Eastcott. Dated 1st July, 1939.

J. A. M. Cameron. Dated 12th May, 1939, with seniority from 1st July, 1938.

R. J. McGill. Dated 12th May, 1939, with seniority from 1st July, 1938.

A. M. Best Dated 12th May, 1939, with seniority from 1st January, 1939.

J. Lightbody Dated 12th May, 1939, with seniority from 1st January, 1939.

H. F. T. MacFetridge Dated 12th May, 1939, with seniority from 1st January, 1939.

The undermentioned short service I. M. S. Officers have been granted permanent commissions as shown below—

Captain A. K. Dev. Permanent commission dated 31st May, 1939, with seniority from 31st May, 1935.

Captain M. Akram Permanent commission dated 2nd June, 1939, with seniority from 2nd June, 1935.

Captain D. S. Raju. Permanent commission dated 4th June, 1939, with seniority from 4th June, 1935.

Captain M. S. Chidha. Permanent commission dated 19th June, 1939, with seniority from 19th June, 1935.

RETIREMENTS

Colonel A. F. Bibonau, C.B., O.B.E., V.D.S. Dated 21st June, 1939.

Colonel W. L. Wilson, O.B.E. Dated 21st June, 1939.

Lieutenant-Colonel M. J. Holgate, O.B.E. Dated 15th May, 1939.

Lieutenant-Colonel K. G. Pandhar Dated 20th May, 1939.

Notes

PROSEPTASINE/SOLUSEPTASINE

ALTHOUGH M & B 693 is the product of choice in gonococcal, pneumococcal, meningococcal and staphylococcal infections, Proseptasine and Soluseptasine have a wide field of use for the treatment of those infections occasioned by the presence of the *Streptococcus hemolyticus* or the *B. coli*.

Proseptasine has been available for three years, and its use throughout that period has steadily increased. It is now generally accepted that Proseptasine is much less toxic than sulphanilamide, and it is interesting to note in the 8th April issue of the *B. M. J.*, it is stated that 'The comparative lack of toxicity of Proseptasine, even when administered to very young children, has been fully borne out'. Soluseptasine, which was introduced subsequently, still finds general favour as the only sulphonamide preparation available for intravenous, intramuscular or intrathecal injection in concentrated aqueous solution.

The present position of both these products is dealt with in a publication, a copy of which we received recently from the manufacturers, Pharmaceutical Specialties (May and Baker), Ltd., entitled 'Proseptasine and Soluseptasine for the Chemotherapy of Streptococcal Infections'. Copies are available to the medical profession on request, from Messrs May and Baker (India), Ltd., 11, Chive Street, Calcutta.

KAPSEALS DESICOL

(PANKE, DAVIS AND CO.)

AN EFFECTIVE CHOLAGOGUE AND CHOLERETIC

KAPSEALS DESICOL present desiccated bile in a form which is readily soluble and similar to whole fresh bile in therapeutic activity. This product is readily soluble on account of a special process of manufacture whereby whole bile is desiccated without coagulation of the proteins.

Each kapséal represents 2.5 c.c. of fresh gall bladder bile.

Indications

Chronic cholecystitis—This inflammatory disease of the gall bladder wall is frequently associated with cholelithiasis and altered liver function. It is estimated that approximately 50 per cent of all women over 40 years of age who have borne children are afflicted.

In these cases control of constipation is important and amongst other measures of treatment the use of bile salts has been suggested. The use of cholagogic drugs in the treatment of liver and gall bladder disease has always been regarded as a very valuable and logical approach to the medical treatment of these cases.

It is generally believed that gall stones are formed frequently during or after an attack of cholecystitis on account of the reduction in the protective colloids or when bile salt concentration falls below a certain level. Administration of bile salts by mouth may favourably influence the course of events in cholecystitis, thereby minimizing the formation of gall stones.

Liver function is improved by stimulating an increased production of normal bile so that equilibrium may be established between its various constituents.

The usual dose of Kapséals Desicol is two kapséals three times daily with meals. When Desicol is taken on a full stomach the gastric distress which may result from presence of bile in the stomach is obviated.

Desicol is supplied in bottles of 50 sealed and airtight kapséals.

Further information regarding this product may be obtained from Messrs Panke, Davis and Co., P. O. Box 88, Bombay.

'BETAXIN'

BITAXIN IN THE TREATMENT OF LEPROSY

Very promising results are being obtained with 'Betaxin' in many aetologically diverse forms of polyneuritic and polyneuralgic disorders. The neurotoxic and infective types appear to respond equally well. The usual dosage used by different workers was 1 mgm., and the total amount administered over some 9 weeks was 45 mgm. Of late, in the light of further experience, the single dose up to 10 mgm. was reached by some, while others state that the rapid cessation of pain and regression of the nerve swellings was most striking. Even advanced bilateral peroneus paralysis improved in a relatively short time so much that practically complete function could be restored.

In conclusion it should be stated that treatment with 'Betaxin' injections has proved of great service in leprous neuralgia occurring as an isolated symptom and in the course of a general reaction to the disease, the response is equally good in the usually intractable neurotic vaso-dilatatory symptoms in the hands and feet, which as a rule are associated with severe pain and paresthesia. The action appears to be highly selective, since the treatment leaves both the general and the arthritic symptom of leprosy wholly unaffected.

Leprosy Review, X 109,39.

THE VIEW OF THE LEAGUE OF NATIONS

ON MALARIA TREATMENT AND PROPHYLAXIS

(Abstracted from the Fourth General Report of the Malaria Commission)

THE Malaria Commission of the League of Nations regards as its main task to help physicians to distinguish what is clearly proved from what is still doubtful. Moreover, where truth is not plainly revealed, the Commission endeavours to ascertain on its own account, by arranging experiments according to a specific programme, as it has recently done the true value of the procedures or measures advocated.

In this country, the wrong idea is widespread that the Malaria Commission recommends a special way of treatment or a special preparation to be used. The statement 'The short Quinine Treatment as recommended in the Malaria Commission' is frequently met with in newspaper articles. A study of the fourth report, however, reveals that no such 'standard' method of treatment is recommended, as the Commission does not deem it advisable to do so. It is stated in the beginning of the report 'We do not think,

however, that it is part of the Commission to instruct medical practitioners in "standard" methods of treating the disease. However the advantages and disadvantages of every method and of every drug now in use in the fight against malaria are described and much is added to the knowledge about the synthetic drugs 'atebrin' and 'plasmochin' which are well known in this country. The report ends by saying:

'As regards the synthetic products, which have only been used in therapeutics for ten years, the Commission hopes that it has discharged the duty which devolved upon it by giving in this Fourth General Report an account of the present state of our knowledge regarding the possible use of "atebrin" and "plasmochin" in the treatment and prophylaxis of malaria. In certain circumstances, as has been shown above, the drugs—representing a notable scientific advance—possesses a very special value.'

GLUCOSE-D. ANNOUNCEMENT OF PRICE REDUCTION

GLUCOSE therapy is now made more widely available by the 20 per cent reduction recently announced by Glaxo Laboratories Ltd. This welcome step now makes it possible to prescribe the treatment for the patient previously debarred by limited income.

Medicinal glucose is frequently prescribed for a wide range of conditions in which easily assimilable and emerging nourishment in liquid form is required. Modern views on glucose therapy, however, agree that when reinforced with calcium and vitamin D (as in Glucose-D), the treatment becomes even more valuable. It is claimed that while the glucose itself is given for its energy-promoting function, the calcium and vitamin D are necessary in certain conditions to improve neuro-muscular tone of the myocardium and the whole system generally. 'The common cardiac disturbances are intimately related to faulty nutrition of the heart muscle', states Martin in his book *Dextrose Therapy* and he goes on to say further that 'the heart, like skeletal muscle, derives much of its energy for contraction from the break-down of glycogen. Inadequate supply of dextrose to the heart eventually produces deleterious effects upon cardiac action'.

In ketosis, too, the vitamin D plays its part. In this condition, when a low fat diet is often necessary for long periods, the patient is subjected to the risk of fat-soluble-vitamin deficiency. The vitamin D in Glucose-D compensates for this deficiency of the calcium-regulating factor. It is thus possible to keep patients on a low fat diet, without producing symptoms of deranged calcium and phosphorus metabolism.

PHOTOGRAPHS FROM EXPOSURE TO PRINT

Photographs from Exposure to Print is the title of a new Burroughs Welleome and Co. booklet. The cover constitutes a novel wallet in which prints may be accommodated.

The various stages in the making of a photograph are explained fully but simply so as to be understood by the veriest beginner. The value of those well-known aids to the amateur photographer, the 'Welleome' exposure calculator and 'Tabloid' photographic chemicals, is amply demonstrated. Readers of this journal will receive a copy free and post free on request from the publishers, Burroughs Welleome and Co., Snow Hill Buildings, London, E.C.1.

VOLPAR PASTE

VOLPAR PASTE is prepared for use in conjunction with rubber cap pessaries. It is intended to be smeared on the rim of the pessary before the latter is placed in position over the mouth of the uterus. Volpar paste contains the same active ingredient as Volpar gels

and the production of these two preparations is the outcome of nearly ten years' continuous investigation conducted by university research workers under the direction of the Birth Control Investigation Committee. During the latter half of this time the work was carried out in association with the scientific staff of The British Drug Houses Ltd. The active constituent of Volpar paste has been shown by laboratory tests to be the most powerful non-toxic spermicide known.

It is essential that rubber caps should be well fitted and never used alone. Volpar paste should always be used with every type of rubber cap in order to seal up the minute openings which will otherwise occur between the cap and the tissues. Such openings, although minute, are still large enough to allow of the free passage of living sperms. It is customary for the physician to advise that either twelve hours should elapse after use or that a douche should be used before the cap is removed. When extreme safety is required a Volpar gel may also be employed. This is frequently considered unnecessary. The ingredients used in the manufacture of Volpar paste are absolutely harmless, but in order to comply with the new poisons rules it is necessary to include the word 'poison' on the label. This is due to the presence of a minute quantity of mercury which is, however, so combined that it is quite harmless and any misgivings on this account may be confidently dismissed.

Readers are referred to p. 243 in our April issue, where an abstract was given of a paper published in the *Lancet*, describing the experimental work with this preparation.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

THE TUBERCULOSIS OF TROPICAL COUNTRIES

(PRIMITIVE TUBERCULOSIS AND THE PARTIALLY MODIFIED DISEASE)

By S. LYLE CUMMINS, C.B., C.M.G., M.D., LL.D.
COLONEL, A.M.S. (ret'd.)

Late David Davies Professor of Tuberculosis, National University of Wales

'WHEN a race previously free from tuberculosis is brought into contact with the germ for the first time, the people will tend to get the disease in an acute and rapidly-fatal form, quite unlike the well-resisted illness recognized as tuberculosis amongst more sophisticated races'.

Such was the theory enunciated by Calmette (1921), Deycke (1914), Borrel (1920), the author (Cummins, 1912) and a host of others some twenty or thirty years ago. This theory has been criticized in several ways and by various men, notably by Bezançon and Arnould (1937), who hold that 'tuberculosis is not really frequent or often serious amongst negroes, except amongst those who change their surroundings or conditions of life, quite apart from the state of allergy or non-allergy of these subjects'. It is the object of this paper to show that, while much may be said against it, the theory of 'primitive tuberculosis' remains as true now as when it was first enunciated.

As to the statement of Bezançon and Arnould, however, that the disease is only very severe and frequent when men move away from their familiar surroundings or change their way of life, a great deal may be said in its favour.

There is no doubt that many cases of chronic tuberculosis are found to occur amongst people who have never left their native surroundings though their relations, going to the mines or other industries, tend to go down with a terrible and malignant type of tuberculosis. Cases of this kind have been reported by Allan (1932), who found, for instance, a woman whom he had seen as a case three years before, still alive and still suffering from tuberculosis though her children did not appear to be ill! This was in the Transkei, a place from which men go to the mines at Johannesburg and where many contract a rapid and fulminating type of fatal tuberculosis. Kleine (1930), too, has described the case of an elderly married but childless woman with pulmonary tuberculosis and a positive sputum who had suffered from the disease for about three years. She was one of five cases discovered out of 9,000 examined at Sikonge in Tanganyika.

It is, then, true or partly true that the disease may proceed quite slowly in primitive peoples

under the restful conditions of their village life, but it would be a great mistake to say that it always does so. For those in intimate contact with a heavily infected person, as, for instance, a man returning sick after a period on the mines, the situation must often be quite different. Macvicar told me of cases of tuberculosis in families which were very severe and numerous, and many such cases have come to my notice from time to time. Still it must be freely admitted that a great many cases are of a chronic type in the villages and that they present a sharp contrast, in this respect, to their brothers or husbands at the mines. I would postulate for this condition a kind of chronicity quite different from the chronic phthisis of Western Europe, a kind of chronicity that would very soon break down into acuteness if the subject were exposed to the least stress. There is a chronic phthisis of guinea-pigs artificially infected with very small doses, and I think that these cases must be very like guinea-pigs in this way; contracting the disease from very small beginnings and having the time, therefore, to elaborate some kind of defence against it. We know, indeed, that very minute doses of infection lead to glandular enlargement without disease in a great many of the men from these villages, as is proved by their arriving at the mines with something like eighty per cent showing a 'positive' to the Mantoux test, and it must therefore be supposed that many are so infected as to get chronic disease also.

'Arriving at the mines with something like 80 per cent positive'. Surely such men are no longer primitive in the sense of not being resistant to the germ! There, I think, we have the whole explanation. The people of the Transkei are *not* primitive in that sense any longer although they were so some 100 years ago. And yet, although the people remaining in their villages sometimes get a more-or-less chronic form of phthisis, those who go to the mines are liable to a terribly acute type. The reason is that these people are only very slightly immunized though extremely sensitive to tuberculin.

The real 'primitive' tribe must now be very rare, if existing at all. Forty or fifty years ago the true primitive may have been comparatively common but with the conquest of the air and other advances he is rapidly being converted into a historic figure—and he may even become *legendary*, if inaccurate writers take up the question in the future. Bezançon and Arnould, although they have seen very clearly the gradual nature of tuberculosis when people remain sedentary and restful, are mistaken in saying that their state remains the same 'quite apart from the state of allergy or non-allergy of these subjects'. It is in their high state of allergy that the danger lies because their state is to all intents and purposes, without any corresponding immunity and their allergy is very much higher in its titre than the allergy of Europe or America.

This was made plain in South Africa during the work of the Commission where the reactions recorded to 1/100,000 of 'old' tuberculin were 55 per cent, to 1/1 million, 51 per cent and to 1/10 million, 48.6 per cent. It will be noticed that the figure was almost exactly the same, even in the highest dilution used. There was immense sensitivity. And yet the immunity was absent or very slight, especially in just those 'boys' that were most sensitive. Of those 'boys' recorded as reacting very positively to 1/5,000 and 1/10,000, and marked as 'PP' or, in other words, vesicating as a result of their tuberculin, the rate of incidence within a year of testing was 1,578 per 100,000. Amongst the 'negatives' the rate of incidence was only 405 per 100,000. But it is to be remarked that the 'negatives' were only negative to 1/5,000 and 1/10,000 and that there were probably many positives, of a less sensitive kind, amongst them. The true negatives were probably very liable to acute tuberculosis, in fact they furnished nearly all the more generalized cases, but the low positives amongst them clearly were much more immune than the high positives. We are, thus, led to the belief that these people, though so very sensitive to tuberculin, are much more liable to tuberculosis than persons of European stock.

Africa is a large continent and it is not to be expected that things should be the same throughout its great extent. There are some races very nearly 'primitive' and some, the majority, very much in the intermediate stage which I have described for the people of the Transkei.

When we turn to the pathological portion of the South African report, we appreciate at once that we are very close to the type of disease which was described by Borrel in the Senegalese soldiers brought to France during the Great War. And yet there are certain differences, when one comes to examine carefully the two series in comparison with one another. The type in South Africa may be appreciated from the following table :—

Lungs and pleura

Acute caseating tuberculosis	70
Acute caseating tuberculosis with excavation ..	102
Miliary tuberculosis only	53
No tuberculosis in lungs (pleura or mediastinum affected)	16
	—
	241

On the other hand, the 'Borrel' gland, described as nearly always to be found above the clavicle was not at all common in South Africa, at least as far as the pathologists were able to make out. Another difference was in the time of appearance of the tuberculosis. Borrel did not see many cases until a year or more had elapsed. The South African cases broke down early, the great majority in three or six months after starting work. That this is a striking character of the recruits now going forward to

the mines will be admitted when it is recalled that the negroes called up from the central and coastal parts of Africa previous to 1912, a much less immune community than the men now recruited from the Transkei and Ciskei or from Portuguese East Africa, went down with tuberculosis so long after their exposure on the mines as 271 days or some cases, from a year to two years, like Borrel's Senegalese. This retardation of disease and death looks like primitive tuberculosis. To find a stage still further advanced than the modern African we may turn to the American negroes who have at least eight or ten generations of association with Europeans to record and who are now only about two generations behind the white man from the point of view of mortality from the disease.

Bushnell (1920) pointed out that these negroes, at the time of the Civil War, had not a much greater death rate than the whites. After that war, the black races of America, previously enslaved, were given their liberty and, at the same time, became responsible for their own lives. Until then, they had had at least a master to whom they could look for shelter and subsistence if not for more, and they had enjoyed the life of agriculturists widely scattered through a rich country with no over-crowding and a fair average of health. With their liberty they became possessed of the right to obtain their own living as best they could and yet had to do so in the presence of a rigid colour bar which kept them in subordinate positions. And there is no doubt that they were also lazy and easy-going in comparison to the pushing citizens of the United States. It is not to be wondered at that they developed a marked amount of tuberculosis; but there has always been a peculiar *character* which has served to distinguish their lesions from those of the white men amongst whom they compete for a living. Louis Dublin (1920), writing on this subject, spoke as follows :—'Tuberculosis of the lungs is the most important cause of death among coloured people. The death rate is more than twice as high among insured negroes as among white policy holders. The disease is a veritable scourge among young negroes. At the ages between 10 and 14 years, the tuberculosis death rate among coloured boys is eleven times as high as it is among white boys of the same age. Coloured girls at the same age period show a death rate eight times greater than white girls'. Opie (1924) speaking of the differences in type of lesion, says :—

'Focal tuberculosis which has its origin in childhood is less prevalent and less advanced in coloured than in white adults. Chronic apical tuberculosis and latent apical tuberculosis are less frequent in the coloured than in the white adult, and when pulmonary tuberculosis occurs in the negro adult it has more frequently than in the white the characters of a first infection. Tuberculous lesions, such as acute miliary tuberculosis and tuberculosis of lymph nodes, which

are often found in white children, occur more frequently in coloured than in white adults. The American negroes are less thoroughly tuberculized than the white race'.

Max Pinner and Joseph A. Kasper (1932) deal with the tuberculosis of the negro as compared to the white and make the following statement:—'Certain significant differences between the two races are shown to exist.

(a) Greater frequency of miliary tuberculosis in the negro (37.3 per cent) than in the white (15.5 per cent).

(b) Greater frequency of hæmatogenous metastases in the negro (84.2 per cent) than in the white (40.0 per cent).

(c) Greater frequency of lymphatic metastases in the negro (66.8 per cent) than in the white (10.8 per cent).

(d) Various qualitative differences in the pattern of tuberculous lesions in the two races'.

They give the most characteristic features of adult negro tuberculosis as:—

Massive lymph-node caseation.

Massive exudative lesions which do not respect the normal boundaries of organs.

A type of generalized tuberculosis without the formation of miliary tubercles but with irregularly scattered nodular foci. These quotations will serve to illustrate what is known about the tuberculosis of the negro in the United States. The disease as it affects the American Indian is also an example of a somewhat earlier 'primitive' tuberculosis becoming, however, modified with the passage of time and the gradual adaptation of the people to their conditions, the available diet of to-day, and the house or shanty as opposed to their old-time teepees.

The Eskimos, too, afford another example of a still earlier type. Suk (1931) describes them as still very free from the disease though becoming infected. 'About thirty years ago', he says, 'Lieutenant Peary brought six Smith's Sound Eskimos to New York; within one or two years four of them were dead. They succumbed to acute tuberculosis'.

Many more quotations might be extracted but these will suffice to show that, like the continent of Africa, America can also produce a great variety of more-or-less modified but still essentially 'primitive' cases of tuberculosis.

It was recently my lot to visit Burma and to study the tuberculosis problem there. I found that the Burmans were suffering from a high death rate, higher than the Indians residing in Burma, and I was able to show that, even in the parts of Upper Burma visited, this high death rate persisted, although the tuberculin index was relatively low, a finding which suggests very strongly that death must be rapid when the disease is contracted. In Rangoon, where the tuberculin index was just as high as in England, the deaths were four times as high, a proof that the population of Rangoon is very susceptible to the disease. The conditions found in Burma convinced me that, apart from

the larger towns, the disease is a relatively new one to the population. I venture to quote one or two of the series of 9,000 von Pirquet tuberculin tests carried out by me to illustrate my meaning:—

Per cent positive von Pirquet tests

	—10 years	—15	—20	Over 20
Upper Burma—				
Mandalay ..	3	14	23	31
Shwebo ..	4	..	7	22.8
Maymyo ..	3.7	4	..	40
Lower Burma—				
Akyab ..	9	16	27	38
Moulmein ..	11	19	26	39
Bassein ..	9	12	26	34
Rangoon ..	26	43	49	61

In Rangoon, things were different. Here, for many years, a large mixed population has striven to exist, often very badly housed and fed, and the handing round of the infection is very common, just as common as in London.

It is to be recalled, however, that in Rangoon the mortality, as far as one is in a position to judge it, is more than four times that in England and Wales, showing that there must be something to put it up, out of proportion to the amount of infection as judged by the tuberculin test. Apart from the poor living conditions, it seems to me that the susceptibility of the people is very largely to blame and that the disease is a comparatively new one to a great many of the persons exposed.

And surely India must tell the same story. The work of Ukil makes this, to my mind, certain, and the observations of Benjamin are a proof that, apart from the great cities, the people of India are also facing a relatively new disease. It is not to be supposed that, tuberculosis is new to places like Calcutta and Bombay. There must be many cities which have paid their tribute to its demands during many generations in the past. But to the essential man of India, the labourer at agriculture or at some pastoral pursuit, it must be, to a great extent, a disease until recently unknown. To quote Frimodt-Møller, 'We have reason to believe, as far as our research goes, that economic, social and hygienic factors, play a far less important part in producing the severe type of pulmonary tuberculosis met with in India than is generally supposed'. The most important part, we believe, is played by a want of acquired resistance.

A TUBERCULOSIS SURVEY IN A SOUTH INDIAN TOWN

By P. V. BENJAMIN, M.B., B.S. (Madras),
T.D.D. (Wales)

*Medical Superintendent, Union Mission Tuberculosis
Sanatorium, Arogyavaram, near Madanapalle,
South India*

M. C. VERGHESE, M.B., B.S. (Andhra)

K. T. JESUDIAN, M.B., B.S. (Madras)

and

C. E. VARKKEY, M.B., B.S. (Madras)

On the invitation of the Saidapet Health Association, a tuberculosis survey was begun in Saidapet, near Madras, in November 1938 and was carried on to March 1939. It was thought that the number surveyed by this time was sufficient both for preliminary conclusions to be drawn and also to see whether the investigation, if to be continued, should proceed along the same general lines, or whether modifications should be made for investigation into special factors which seemed of interest and importance.

The beginning of the survey was possible without much preparatory work in the town, as the excellent efforts of the Saidapet Health Association had paved the way by its several years of work among the population, which had produced to some extent a health consciousness and a comparatively welcoming attitude. The result was a large amount of co-operation from the general public, to which was added the whole-hearted co-operation of those associated with the Saidapet Health Association.

Saidapet is about six miles from the business centre of Madras, to which it is connected by electric trains and very frequent buses. It has a population of about 33,000, and the basic occupations are hand-loom weaving, hand-dyeing, pottery-making, *jutka*-making and repairs, gold-smithing and *dhobying*, although some of these occupations have in recent years been hard hit by modern developments. In general, it may be said that Saidapet is a typical south Indian town in its economic, social, hygienic and religious customs and methods of living.

Nature and method of the survey

An attempt was made to include every individual in each area surveyed, and, in the investigation so far carried out, certain areas were selected to give as far as possible a fair sample of the various communities, economic, social and living conditions found in the whole town.

In the area surveyed, a little over half of the whole population of the area was seen, 553 out of 1,023 houses, and in the houses visited almost always all members of the 900 families living there were included in the investigation.

The survey included the Mantoux test, physical and x-ray examinations of those strongly positive, and those with symptoms and, where possible, sputum examination. An investigation was also made into the family regarding social status, house condition, medical history, including history of contact with tuberculosis, and diet. The information was collected by personal visitation, very often repeated several times by the doctors and health association staff. For convenience of classification, the details for all individuals were entered from the permanent records onto cards.

Technique and Mantoux test

In the beginning of the survey, an injection of 1/10 c.c.m. of 1/1,000 (Burroughs Wellcome & Co.) old tuberculin (human) was made, with an intradermal needle, into the flexor surface of the skin of the forearm, after previous cleansing. If any individual showed symptoms suggesting tuberculosis, a strength of 1/10,000 tuberculin was used. If this first injection was negative, the test was repeated, using 1/100 tuberculin. But owing to the difficulty of persuading people to have a second injection, this method had to be abandoned, and instead one injection of 1/500 dilution of tuberculin was used for the general survey, and 1/10,000, as before, for suspected individuals.

The reading of the test was done 48 hours after the injection, and in a few cases 72 hours after, and readings were noted according to six classifications, negative, \pm a reaction of below 5 mm. in diameter, + a reaction of from 0.5 to 1 cm., ++ of from 1 cm. to 1.5 cm., +++ above 1.5 cm., ++++ when there was vesication or necrosis associated with strong induration.

All injections and readings were done by doctors experienced in the test.

Physical and x-ray examinations

Physical examination was done in all with suspicious symptoms or all with strongly positive tuberculin reactions, even without any symptoms, except for a few who refused examination.

X-ray photos were taken of approximately only one-third of those physically examined, as the survey party did not have an x-ray outfit at its disposal, and it was possible to get about 20 photos only, taken once a week. We are

indebted to the Barnard Institute of Radiology, Madras, for their willing co-operation in this respect, which involved considerable extra work for them.

Findings in the survey

The investigation covered in all 3,309 individuals, 3,124 in Saidapet municipal area, and 185 in an adjoining *cheri* in Mambalam. For this last group full details regarding family, social condition and so on were not collected. The 3,124 individuals in Saidapet were in 900 families living in 23 streets in different parts of the town. There are not included 75 persons in whom the skin test was not read, and 36 who refused to have the stronger dilution but who were negative with 1/1,000 dilution.

(a) Extent of tuberculous infection

(i) *General*.—Of the 3,309 persons examined, 1,924 or 58.1 per cent showed a positive reaction, namely, 1,234 or 37.3 per cent +, 237 or 7.2 per cent ++, 386 or 11.7 per cent +++, and 67 or 2.0 per cent ++++; 1,009 or 30.5 per cent showed a completely negative reaction, and 376 or 11.4 per cent showed a ± or doubtful reaction.

If the 1,924 positives are taken by themselves, it will be seen that 1,234 or 64.1 per cent were +, 237 or 12.3 per cent were ++, 386 or 20.1 per cent were +++, and 67 or 3.5 per cent were ++++.

If the adults and children under 15 are separated, the results may be tabulated as follows:—

infection* were found in no. 21 street with 174 people and 23.6 per cent positives, and no. 7 street with 92 persons and 37 per cent positives.

The details for all the streets are given in tables II (a) and (b).

(iii) *According to sex*.—An examination of the figures was made with regard to sex. The figures for the Mantoux test are given in table III.

(iv) *According to community*.—The great majority of those examined were Hindus, as these form the majority of the population in the town, being about 30,500, out of 33,000; Muslims, according to the latest figures available, number 1,341, and Christians 1,099. Approximately the same proportion was found in the area surveyed. The figures for the Mantoux test are shown in table IV.

(v) *According to occupation*.—The figures for the Mantoux test, as regards different occupations, are shown in table V.

(vi) *According to economic status*.—In the examination of the economic status of the people, they are divided into groups according to income per head in the family, children included.

The Mantoux results for the group are shown in table VI.

While the above table gives the general figures for the whole group, there are considerable variations if the groups are divided according to streets. Taking only adults, to eliminate any variation which might be due to a different proportion of children in each street and omitting percentages of any groups below 10, the figures

TABLE I

Number and percentage of tuberculous infections as shown by the Mantoux test

	Total number	—	±	+	++	+++	++++	Positives
Adults ..	1,963	372 or 19.0 per cent	221 or 11.3 per cent	868 or 44.2 per cent	180 or 9.2 per cent	282 or 14.4 per cent	40 or 2.0 per cent	1,370 or 69.8 per cent
Children ..	1,346	637 or 47.3 per cent	155 or 11.5 per cent	366 or 27.2 per cent	57 or 4.2 per cent	104 or 7.7 per cent	27 or 2.0 per cent	554 or 41.2 per cent
TOTAL ..	3,309	1,009 or 30.5 per cent	376 or 11.3 per cent	1,234 or 37.3 per cent	237 or 7.2 per cent	386 or 11.7 per cent	67 or 2.0 per cent	1,924 or 58.1 per cent

The above table includes all individuals tested, but in the subsequent figures 349 people are omitted, as detailed information was not obtained about them as regards other factors, the figure 349 includes 185 in the *cheri* of Mambalam.

(ii) *According to streets*.—If the extent of tuberculous infection is examined from the point of view of streets, the 23 different streets show variations from 85.2 per cent to 20.0 per cent positive, the highest percentages of infection being found in no. 19 street with 393 people tested, where the positives were 85.2 per cent, no. 14 street with 179 people and 78.2 per cent positives, no. 18 street with 168 people and 73.2 per cent positives; the lowest percentages of

for the different streets are as shown in table VII.

(vii) *According to living space*.—In order to see the effect of crowding on the tuberculosis infection rate, the 2,960 people were grouped according to the amount of living space per head (kitchen and store-room included).

The figures for the whole group are shown in table VIII.

This table may be misleading if no account is taken of a wide difference in type of housing accommodation; for example, in streets nos. 3

* Excluding street no. 17 in which there were only 10 persons examined.

			Children ..	19	8	42.1	98	16	16.3

tuberculosis, those who reported suspicious symptoms and those who showed a ++, +++ and ++++ Mantoux were examined physically, and as many as possible had an x-ray photograph taken. Of 704, who were selected for examination for one of the above reasons, 13 refused examination, and 53 could not be found, leaving 638 who were examined by physical examination, and of these 241 were examined by x-ray also.

Total number examined physically ..	638
Number showing abnormal physical signs requiring further investigation ..	186
Number showing signs of non-pulmonary tuberculosis ..	6
Number showing no physical signs of tuberculosis ..	446

Of the 186 showing some physical signs in the lungs, 126 were x-rayed; in addition, 1 with bone tuberculosis was x-rayed, and also 114 showing a strong Mantoux but no physical signs suggesting tuberculosis.

The results of the physical and x-ray examinations were classified as follows:—

- Those definitely showing an active tuberculous lesion which needed treatment.
- Those showing signs suggesting active tuberculosis but who needed further observation before it could be decided whether treatment was necessary.
- Those who showed signs of tuberculosis, probably not active, but who should be checked up from time to time.

Of the 60 persons who showed physical signs in the lungs but who were not x-rayed, evidence of active tuberculosis was certain in 5; the others needed further examination and observation for certainty. Besides, 5 patients not x-rayed were

found to be suffering from non-pulmonary tuberculosis, 3 glandular, 1 abdominal, 1 bone.

	WITH x-RAY SIGNS			
	Active disease requiring treatment	Further observation needed	Checking needed	No x-ray signs
Those showing physical signs (including 1 case of bone tuberculosis).	18	47	8	54
Those showing no physical signs but with strong Mantoux.	3	57	6	37
Those with no physical examination.	2	3	7	..
TOTAL ..	23	107	21	91

This makes a total of definitely active cases of tuberculosis of 33. Experience with observing the type of case included under those classified as needing further observation, leads us to conclude that a large percentage of those 107 individuals also have an active lesion requiring treatment. It is specially important to note that of those 107 individuals, 54 were children under 12 years of age.

(x) *Sputum examination*.—Sputum examinations by the ordinary smear method were made for 124 persons, in whom the examination was repeated one to three times in 90. A

positive sputum was found in 8 persons, all of whom showed both physical and x-ray signs of active tuberculosis.

(xi) *Deaths from tuberculosis during survey.*—Of those classified as having active tuberculosis needing treatment, 4 died of tuberculosis during the survey, and of those classified as needing further observation, 2 also died of tuberculosis. Further, 2 others tested by Mantoux died of tuberculosis, without other examinations being made.

In addition to the above deaths from tuberculosis among those in the survey, information was given that 7 others also died of tuberculosis in the streets in which the survey was made but who had not been examined. It may be remarked that several houses in which it was definitely known that there were cases of active tuberculosis, and some of whom were even under treatment, refused co-operation, not wishing it to be known that they had tuberculosis in the family.

Therefore, the total deaths from tuberculosis in the area surveyed during the period of the survey was known to be 15.

Discussion

(i) *General infection rate.*—Using mostly an intradermal injection of a 1/500 dilution of tuberculin, a positive reaction was found in 1,924 or 58.1 per cent in a total of 3,309 people. There has been little work hitherto in India dealing with an unselected population and so comparisons are not easy to make. An investigation in Chittoor District (Benjamin, 1938) by the von Pirquet test of 6,665 unselected people showed a percentage of 37.8 for adults and 10.8 for children under 15, and 40.1 for adults and 11.6 per cent for children living in small towns, and 30.8 per cent for adults and 8.2 per cent for children living in villages. It is to be expected that the percentage of positives in a town like Saidapet close to Madras would be higher than in small towns up-country.

(ii) *Sex and community.*—The figures for sex show no appreciable difference.

As regards the figures for community, apart from the Hindus, the figures are very small for any reliable deductions to be drawn as to community infection rate.

(iii) *Occupation.*—Of the large groups, the adult weavers show a high infection percentage of 83.5, although several smaller groups, such as *beedi* makers and goldsmiths, show an even higher percentage. It is noticeable, too, that children engaged in these occupations show a very high rate also, being for weavers 70.1 per cent, and for the few *beedi* workers 63.7 per cent; all the other figures for children, even those working, being considerably less, between 41 and 50 per cent. Apart from the figures mentioned above, there is not much variation in different occupations.

(iv) *Infection rate in children.*—The figures for Saidapet, separating adults and children

under 15, show a positive Mantoux for adults 69.8 per cent, and children 41.2 per cent. This indicates a high infection rate for the whole population, but it is specially high for the children, much higher than is normally found in such investigations in Europe and America, and very much higher than the figures for the town children in Chittoor District. For example, an investigation by Chadwick and Zacks (1930) into 101,118 children in Massachusetts showed 28 per cent positive in children under 15 years of age, mostly in towns, and Dow and Lloyd (1931) dealing with 1,220 children, partly contacts of tuberculous parents in London, found 27.2 per cent positive. The figure of 41.2 per cent for Saidapet for children under 15 years of age, therefore, indicates a serious situation with very early infection. It also indicates that infection takes place mainly before the children are much in contact with the outside world. It points rather to serious home, or possibly school, infection which requires further investigation.

(v) *Variation in infection in streets.*—Another point worthy of note is the high infection rate of certain streets such as for example no. 19 street where as many as 211 out of 232 adults show a positive Mantoux, i.e., 90.5 per cent, and children as many as 124 out of 161, or 77.0 per cent. On the other hand, in no. 21 street only 35 out of 79 adults show a positive, i.e., 44.3 per cent, and 6 out of 95 children, i.e., 6.3 per cent. No. 19 street is a crowded street with a number of different families living in each house, whereas in no. 21 street the houses are mostly government quarters, not crowded together. In most of the streets the various occupations are fairly well distributed, but in no. 9 street the majority of people are weavers. The high infection-rate (68.1 per cent) in this street may be due to the occupation and the conditions under which they work. As was pointed out under the discussion on occupation, the figures for the weavers were one of the highest, and 171 of the 264 adults in this street are weavers, and 37 of the total number of 107 children are also working at weaving. Of the adult weavers in this street, 83.1 per cent were positive, and of the children 78.7 per cent.

(vi) *House space per head and sleeping space.*—As one of the factors which might cause variation in street infection rates, an investigation was made into the cubic feet of space per head for each individual and also the number sleeping in a room.

When all the houses in the survey were included, there was surprisingly little variation in infection percentage, whether the living space was small or large, the only noticeable drop being for children in the houses with over 1,500 cubic feet per head, the percentage being only 16.3, as compared with from 36.8 to 46.9 per cent in the other groupings. From the general figures in table VIII one would seem to be justified in inferring that the size of the house does not appreciably influence the infection rate, at least

as a factor by itself. On the other hand, when a group of houses in which the general style of living is quite different are excluded (table IX), there does seem to be a higher rate of infection for the small houses of the type occupied by the general population of the area surveyed. It is noteworthy that the houses in the two streets excluded (no. 3 and 5) are isolated from the main town streets and are situated in fairly open surroundings, and in addition the people who occupy these houses mostly sleep outside the houses. This may be an explanation for the considerably lower rate of infection found among these people, though their houses are small. Again it should be noted that in another area where the infection rate is low, no. 21 street, the houses here also are separated from the main town and stand in open ground, although they are of a far different type from those in streets 3 and 5, being houses built by government for government officials of the secretariat.

Another point which has a bearing on the question of living space and infection is dealt with in tables X and XI where it will be seen that in those streets where it is possible to find sufficient numbers of houses in the various groups for comparison, there is not a really significant variation in infection-rate in the various cubic space groupings. The difference seems to be a street difference, i.e., the infection-rate is fairly constant for all houses in a particular street; this is possibly due to some peculiarity in the habits of the people of that street. This will be commented on again later.

If we group the people tested according to the number sleeping in one room, little difference again is seen, the variation in adults being between 68.2 and 73.0 per cent positives for persons sleeping in a room up to 6 in a room, and for children of from 32.0 to 51.0 per cent, the lowest figure surprisingly being found for those with only one room for 6 or more persons. One possible explanation is that when the weather allows, many of those in the crowded houses sleep in the open. But the whole question seems to require further investigation with a larger group, as it goes contrary to what is found in other parts of the world.

(vi) *Economic condition.*—Tuberculosis is commonly said to be 'the poor man's disease', but the figures obtained so far in Saidapet definitely contradict this idea and in fact would generally seem to point the opposite way.

In the general table VI there is very little variation except in one group which happens to be a small group (those with a monthly income of Rs. 21 to 25), and this particular variation might be due to an 'error in sampling'. The wealthiest people do not show any significantly less infection-rate than the poorest. On looking into the question of variation according to streets and monthly income, we find again a street variation irrespective of the economic factor. For example, in table VII it will be seen that there is a variation of from 40.0 to 92.0 per cent

of infection in the poorest group in the different streets, and from 40.0 to 91.7 per cent of infection in the richest group in the different streets. But in the individual streets there is not much variation in the percentage of infection in the different economic groups, e.g., in no. 14 street the variation is between 75 and 92 per cent, and in no. 19 street between 86 and 100 per cent. At any rate, it is not the economic condition of the people which is the prime factor in the spread of infection.

(vii) *Contact infection.*—It is well known that the tuberculosis infection rate is much higher in those living in close contact with open cases of tuberculous. Our investigation confirms this by the figures for contacts being 70.4 per cent, as against 56.0 per cent for those giving a history of no contact. It should be noted that as many as 152 families with 621 persons out of 900 families give a history of contact and this contact was, with few exceptions, in the family itself.

The difference in the positives in contact and non-contact for adults and children separately is shown in table XIII, where contact adults show 80.0 per cent positive and 68.2 in non-contacts, and in children 55.8 per cent positives in contact and 38.5 per cent in non-contacts.

In considering contact and non-contact infection in certain streets, there is again found to be a wide street variation, adult contact showing a positive varying from 58.1 to 93.4 per cent in different streets, and children contacts from 42.1 to 93.8 per cent. In non-contacts also the variation in adults varies in different streets from 40.3 to 89.7 per cent, and in children from 3.6 to 77.1 per cent.

The difference between contact and non-contact infection is marked in the streets which show a general lower average of infection, but in the streets showing a general high infection rate there is not very much difference between contacts and non-contacts. This would seem to suggest that all living in the badly infected streets are practically living as contacts.

(viii) *Active tuberculous disease.*—In the survey 33 individuals were found to be suffering, without any doubt, from active tuberculosis requiring treatment. In addition, 107 needed further immediate observation, because of physical and x-ray findings, and, judging from experience elsewhere in the observation and following up of such cases, the probability is that even as many as half of them would be found to be suffering from an active tuberculosis, needing treatment. It may be mentioned that 2 of this group classified as needing immediate observation died of tuberculosis before the survey was completed. Another serious aspect of the problem is that 54 out of the 107 needing immediate observation were children under the age of 12. It is everywhere recognized that tuberculous disease in children is far more fatal than in adults.

If our inferences are correct it means that among the 3,309 persons examined, about 87 were suffering from active disease requiring immediate treatment, which is a very high figure, denoting a very serious situation.

A further point to be noted here is that many of the cases of active tuberculosis were only discovered by means of x-ray examination, and, therefore, if it had been possible to use x-ray examination in all cases, it is likely that still more of cases of active disease requiring treatment would have been discovered. That physical examination without x-ray is not enough has been proved by experience of all tuberculosis workers and is shown again here. Many cases of early tuberculosis cannot be detected without x-ray.

Another fact we should like to point out is that a good number of those suffering from active tuberculosis in Saidapet, even with a positive sputum, were going about their daily work, not knowing they were sick, and not conscious of their being a danger to society. For example, in this group there was one bus conductor, one clerk in a shop, one student attending college, and one watcher of a *choultry*.

Tuberculosis mortality

During the last 6 months it was ascertained definitely that 15 people had died of tuberculosis in the area surveyed. The total population of the area is approximately 6,500. This works out at a mortality rate for tuberculosis of 462 per 100,000 of the population. This is a minimum figure. It is a very high mortality rate compared with, for example, the figure for Manchester, England, of 104, which itself is a high figure for England, where the average is only 76 per 100,000 (Pearson, 1937).

If the other areas of Saidapet show the same mortality rate, it will mean that about 150 people die of tuberculosis every year in Saidapet.

Conclusion

In examining, the question of tuberculous infection-rate in the town of Saidapet, again and again we have been driven back to the fact that, whatever grouping we make, the infection-rate seems to run in streets. If we examine according to general infection-rate, according to economic condition, according to living space, according to contact with cases of tuberculosis, the rate varies in different streets. This holds good with both adults and children. What is it in these streets which in one instance causes a high infection-rate and in another a low rate? One possible clue is given in what has been mentioned that in streets 3, 5 and 21, the houses are separate, although in the first two the people are poor, and in the last comparatively well-to-do. Each family, and by that is meant father, mother and children with but few other relatives, lives in a single house. In the other streets, the houses are all joined together, and large families with many relatives live in a single

house, and if the family itself does not fill the house, then the rest is let out to tenant families, several of whom may be in a single house. Although the families are separate, there is much mixing together, and the effect is one large family. The result is that, if tuberculosis is introduced into a family and clinical disease results in even a single member, then all of the families in that house are contacts, and contacts to what may be massive infection. Moreover, the close proximity of the houses, and even the space in the houses, cause much interchange of people from one house to another, even if the families are different, and these, too, become contacts. This would suggest that it is not mainly the economic factor or the size of the house or the sleeping accommodation, but the method of living, which is the principal cause of spread of infection.

The survey so far carried out, even with a small proportion of the population like 3,309 people, is yet sufficient to show the seriousness of the tuberculosis problem in Saidapet. This position has only been revealed by the survey and was unknown before. If the rest of the town is as infected as the area surveyed, there are probably 800 to 900 people suffering from active tuberculosis, needing treatment in Saidapet.

This investigation has been carried out in Saidapet, but there is no reason to suppose that Saidapet differs in any way from other towns in south India as regards tuberculosis infection and morbidity. If this is so, it shows the magnitude of the tuberculosis problem which has to be faced, and the complexity of that problem.

Acknowledgments

We should like to acknowledge, with thanks, the advice and help of Dr. Frimodt-Møller from the beginning of the survey; also of the Rev. R. M. Barton, Dr. P. K. Koshy and several other members of the staff, Dr. A. Chandy and Dr. Vaidyalingam, doctors under training, who have helped us in the analysis of statistics and the preparation of the paper; also Dr. P. Sundaresa Rao, of the Saidapet Health Association, and his assistants, who rendered great help in the field work. Our thanks are due to the Barnard Institute of Radiology, Madras, for co-operation in taking the x-ray photos. Without the inspiration and co-operation of Dr. R. G. Cochrane, of the Chingleput Leper Settlement, and of Mrs. M. Buck, of the Y. M. C. A. College of Physical Education, the survey could not have come into existence, and they have been constantly helping throughout the period. Nor should be omitted the splendid co-operation of the general public of Saidapet.

OBSERVATIONS ON SOME EPIDEMIOLOGICAL FACTORS OF TUBERCULOSIS IN SOUTH INDIA

(AS STUDIED FROM CASES AT THE GOVERNMENT TUBERCULOSIS HOSPITAL, MADRAS)

By K. S. SANJIVI, M.B.
(Madras Medical Service)

This paper attempts to draw certain conclusions on the epidemiology of pulmonary tuberculosis from an analysis of a thousand consecutive open cases and a thousand radiographs, studied at the Government Tuberculosis Institute, Madras, during 1936-37.

Table I gives the age incidence of the 1,000 open cases, 709 males and 291 females :—

TABLE I

Age	MALES		FEMALES	
	Number	Percentage	Number	Percentage
Less than 15	6	0.81	6	2.01
15-21	151	21.56	109	37.06
25-31	270	37.0	111	37.74
35-44	163	22.82	47	15.98
45-54	72	10.08	15	5.10
55-64	40	5.60	3	1.02
Above 64	4	0.56	0	0.0

It will be seen that high tuberculosis morbidity in females starts a decade earlier than in males and does not appear to be so much a problem in elderly women as in elderly men. That more than 16 per cent of male consumptives are past 45 years is an important fact to be remembered, as a large number of them pass off as chronic bronchitis, 6.9 per cent of all the cases had wheezing at the time of examination. It is well to remember that 'all that wheezes is not asthma'. The importance of this distribution to the economic life of the community by 83.3 per cent of the ailing men and 91.9 per cent of the ailing women being between the ages of 15 and 44, is too obvious to be dilated upon*.

Figure 1 shows that tuberculosis is no longer confined to urban areas. This rural permeation is only to be expected, considering the rapid

communications that exist to-day, the frequent exchange of men between the fields and the factories, and the comparative virgin state of the soil in the villages.

Fig. 1.

The 709 males have been classified below according to their occupation :—

TABLE II

Showing occupational incidence of tuberculosis

Farmers	.. 89	Weavers	.. 15
Coolies	.. 71	Tailors	.. 15
Mill-workers	.. 55	Sweepers	.. 15
Clocks	.. 45	Motor-drivers	.. 15
Food-handlers (milkmen, cooks, bakers, etc.)	.. 45	Carpenters	.. 14
Petty merchants	.. 39	Blacksmiths	.. 13
Peons	24	Beedi-makers	.. 12
Domestic servants	24	Masons	.. 8
Press-workers	.. 23	Police-men	.. 8
Students	21	Cartmen	.. 8
Teachers	.. 18	Fishermen	.. 7
Gold- and silver-smiths	.. 16	Painters	.. 5
		Unemployed	.. 71
		Miscellaneous	.. 33

When we consider the numbers actually engaged in each of these occupations (of which we have no accurate information) perhaps tuberculosis surveys amongst mill-workers, press-men, tailors, beedi-makers and weavers are likely to yield valuable data.

Whenever tuberculosis is diagnosed in an upper class family—and it is by no means rare among them—one hears loud protestations that it cannot be, as there has been no previous family history. Even so, how can the richest escape tuberculous infection when the food-handlers and children-handlers (teachers, servants, motor-drivers, etc.) form as much as 16.7 per cent in the above table.

* These figures do not present the true sex and age distribution of tuberculosis, but only the distribution amongst those attending the tuberculosis institute. The economically more important members of a household would tend to apply for medical relief first.—EDITOR, I. M. G.]

(Continued from previous page)

Dow, D. J., and Lloyd, W. E. (1931) *Brit. Med. J.*, n, p. 183.
Pearson, S. V. (1937). *Brit. Journ. Tuberculosis*, Vol. XXXI, p. 149.

TABLE III

Showing death rate of children of tuberculous persons

	Number married	Number of children born	Number of children (under 10 years) dead	Percentage dead
Males ..	354	1,324	528	39.9
Females ..	216	623	164	26.3

The percentage death rate for children under 10 in the general population is 4.0 (Russell, 1938)*. The death rate in the children of tuberculous parents is considerably more.

The definitely greater risk to the offspring when the open case is the father may be due to two reasons :—

Firstly, an incapacitated parent stays indoors all the time, and,

Secondly, the set-back in the economic level of the family due to the bread-winner's illness tells on the resistance of the children.

Of the 216 married women, 58 or 26.9 per cent dated their symptoms from a previous child-birth or abortion. Tuberculosis should not be forgotten in the differential diagnosis of fevers in child-bed. The number of the pregnancies did not appear to be of any significance.

TABLE IV

Showing the duration of the disease at the time of seeking treatment at the institute

	Number of cases		Number of cases
Less than 15 days ..	32	3 to 6 months ..	265
15 days to 1 month ..	87	6 to 12 " ..	175
1 to 2 months ..	119	More than 1 year ..	189
2 to 3 " ..	133		

It will be seen that only a third of the total have sought treatment earlier than three to six months after the manifestation of symptoms. Unless something effective is done to avoid this general delay it will be difficult to convince people that tuberculosis is curable.

TABLE V

Showing the initial symptoms complained of in these 1,000 cases

Fever alone	73
Cough alone or with weakness	405
Fever and cough	386
Hæmoptysis	40
Loss of weight or weakness	58
Pain in the chest	28
Dyspepsia	10

*[We do not understand this statement; in the report quoted the *infantile* mortality alone for Madras in 1936 is given as 164.1 per 1,000 live births, or 16.41 per cent.—EDITOR, I. M. G.]

Apart from the cases of initial hæmoptysis, 224 others had spat blood some time during the illness, hæmoptysis thus occurring in 26.4 per cent of all the cases. The importance of not ignoring a persistent unexplained cough, fever, weakness or hæmoptysis must be urgently brought home to the general practitioner. But, will educating the general practitioner alone ensure diagnosis? From table VI it will be seen that 49.7 per cent in this series had tried various non-descriptive, non-allopathic remedies before coming to the tuberculosis institute.

TABLE VI

Allopathic hospital or dispensary ..	406
Allopathic private practitioner ..	97
Non-descriptive remedies ..	497

This takes us to the larger question of organization of medical relief for the poorer classes, which is outside the scope of this paper. The fact that 82.7 per cent of these 1,000 open cases had gone beyond the stage of suitability for artificial pneumothorax further illustrates the urgent need for facilities for early diagnosis, and treatment. With the very meagre institutional accommodation we have, the vast majority of these advanced cases are turned back to their homes where conditions are ideal for the rapid dissemination of the seeds of tuberculosis. Some means of segregating the advanced open cases must, therefore, form a vital part of any programme of tuberculosis control.

Every case which, on a consideration of the symptoms, Mantoux test, sputum examination and clinical examination by two independent observers (the assistant surgeon and the director) appeared to be a case of pulmonary tuberculosis in whichever stage was x-rayed. In our country sifting of other evidence has to precede radiological examination as we cannot afford to use x-rays at the very commencement of our work in a tuberculosis clinic or in a survey. One thousand consecutive radiographs have been looked into and the tale they tell summarized.

TABLE VII

A. No active tuberculosis	
1. Non-tuberculous (bronchiectasis, abscess, etc.) ..	31
2. Hilus shadows with calcified spots ..	44
3. Peri-bronchial fibrosis ..	85
B. With active disease	
1. Without cavitation—	
(a) Deposits of varying size and extent ..	221
(b) Pleurisy (only visible lesion) ..	28
(c) Peri-bronchial infiltration ..	231
2. With cavitation—	
(a) Fibro-caseous disease ..	315
(b) Fibroid phthisis ..	45

Type B, 1, c in the above table, perhaps, requires a word of explanation. The 231 patients with distinct infiltration, linear and

apparently peri-bronchial in distribution gave a history of cough, bouts of fever, lassitude, etc. The Mantoux reaction and clinical examination gave further grounds for suspecting tuberculosis and they were x-rayed.

I can recall several cases in each of which a skiagram taken at the onset of the illness showed these appearances which were ignored and a few months later dense circular deposits appeared in the same region. But mostly, this type of case is resistant with a tendency to localization in fibrosis. Descriptions of similar appearances are given by Fishberg (1932) although he says 'the idea of peri-bronchial tuberculosis has been abandoned at present'. Perhaps it is best to call this type 'early spreading granuloma' following Wingfield (1937) and with him insist on the diagnosis of tuberculosis at this stage.

TABLE VIII

Showing percentage incidences of different lesions

	Present series	Dr. Benjamin's series (1938)
All cases with cavities ..	42.9	73.3
Cavities with hard fibrous walls among the above ..	20.0	5.9
Mid-zone lesions—		
In left lung ..	28.7	73.1
In right lung ..	26.6	71.2

For purposes of the above table, the percentage has been calculated on the 840 active cases, excluding the 160 cases in group A with no active disease.

A sanatorium gets only selected cases referred to it by other doctors, and usually, in our country, only at a stage when the private doctor feels he can tackle it no longer. It is hardly justifiable to conclude 'that the disease in Indian patients is acute, rapidly developing with little tendency to show a natural resistance and healing' on a study of a definitely selected sample. The present study based on an out-patient population of a tuberculosis institution shows that such an alarmist view need not be taken about the type of the disease. Even this series is, after all, a selected group, and it is only by the extensive random surveys of unselected groups together with the recognition of a stage of 'tuberculosis minor' that the exact situation regarding the type of tuberculosis in south India can be gauged.

My thanks are due to Dr. K. Vasudeva Rao, the Director, for permission to make the above study at the Government Tuberculosis Institute, Madras.

BRONCHIECTASIS : ITS ÆTIOLOGY, PATHOLOGY, DIAGNOSIS, PROGNOSIS AND TREATMENT

By A. C. UKIL

and

K. N. DE

(From the Department of Chest Diseases, Medical College Hospitals, Calcutta)

THE term 'bronchiectasis' indicates a condition in which the bronchial tubes are dilated beyond their normal shape and size. Although during the last twenty years, careful clinical, radiological, bronchoscopic, bacteriological, histopathological and surgical work and experimental studies in animals have been carried out on chronic pulmonary suppurations and have contributed greatly to a clearer understanding of the conditions, still all the factors responsible for the causation of bronchiectasis are not yet well understood. Our knowledge on the subject has, however, become much more precise since the introduction of lipiodol bronchography by Sicard and Forestier (1922), the use of the bronchoscope in examining the bigger bronchi, and the anatomo-pathological study of lobectomized lungs, during the last few years.

The present paper is based on 160 cases confirmed by lipiodol bronchography done between 1931-38. An earlier paper by Ukil and De (1935) based on 80 cases, was presented before the Indian Science Congress. Although we are dealing with the subject in a warm climate, it will be seen that the condition is not at all rare and that practically all categories of cases are encountered, both in children and adults. In the absence of a correct appreciation of facts, cases have been wrongly diagnosed and treated, and even referred to sanatoria for the treatment of what had been wrongly diagnosed as pulmonary tuberculosis.

Ætiology and pathology

Bronchiectasis may be congenital or acquired. Congenital bronchiectasis is extremely rare and hence bronchiectasis is almost always an acquired disease.

In *congenital bronchiectasis*, the lesion is due to some anomaly of bronchial or pulmonary development. Two forms are met with—cystic and atelectatic. In the former, multiple cyst-like thin-walled dilatations, caused by anomalous bronchial or alveolar development, occur usually in one lung. They are frequently dry. The pleural surface is generally free from adhesions and looks bluish through the thoracoscopic. In the latter, dilated bronchi are found

 Wingfield, R. C. (1937). *Pulmonary Tuberculosis in Practice*. Edward Arnold and Co., London.

associated with congenital atelectasis. Some of these broncho-pulmonary anomalies may remain symptomless and undetected until some time in adult life.

In *acquired bronchiectasis*, the essential change is a weakened bronchial wall due to the absence, atrophy, damage or destruction of the muscular and elastic tissues of the wall, frequently owing to infection. The mucosa becomes thickened and covered by inflammatory exudate and there may be a variable amount of associated inflammatory changes in the regional pulmonary parenchyma. As a result of the destructive changes, granulation-tissue formation and epithelial relining occur inside the damaged bronchi and cavities. In some cases, however, little or no inflammation of the bronchial wall is noticed and the principal change is an atrophy of the muscular and elastic tissues, along with regional atelectasis and peri-bronchial inflammation. Recent work on pulmonary inflammation indicates that the two types of change are frequently associated in one case, as it has been noticed that atelectasis of various grades frequently occurs during the healing of pneumonic diseases and in tuberculosis.

Bronchiectasis commonly follows broncho-pneumonia or bronchitis complicating whooping cough, measles, influenza and other acute infectious diseases, or results from the aspiration of an infected foreign body or of exudates from the upper respiratory tract (especially the nasal sinuses). The condition may be unilateral or bilateral, but the chief factor is the weakening of the bronchial wall. Partial obstruction of a bronchus may cause a rise in intra-bronchial pressure and thus be a contributory factor in bronchial dilatation in the presence of bronchi with weakened walls. Bronchial obstruction may occur from *within* (e.g., by aspirated foreign bodies, tenacious or inspissated sputum, neoplasm, gumma, etc., or inflammatory stenosis due to pneumonia, tuberculosis, etc.), or from *without* due to compression stenosis by adenopathy, aneurysm and obstructive atelectasis. Obstruction within the bronchus leads to stagnation of secretion in the lung area supplied by the obstructed bronchus, which again leads to decrease in normal movement and aeration of the area, factors which favour infection and consequent weakening of the bronchial wall.

In cases of bronchiectasis, a large number of mouth bacteria, especially staphylococci, streptococci, diphtheroids, pneumococcus, *M. catarrhalis*, *B. influenzae*, gain entrance into the lower broncho-pulmonary tract, multiply there and cause a variable degree of bronchitis and degeneration of the muscular and elastic tissues of the wall. In these cases there is no appreciable odour in the purulent or mucopurulent sputum, but in adults where anaerobic organisms, especially fuso-spirochetal associations, are present, the sputum becomes offensive in odour. So far as the action of the micro-organisms is

concerned, the nature of the tissue changes depends partly on the number, type and virulence of the organisms and partly on the sensitiveness of the tissues to the particular bacterial allergens concerned.

Even if we imagine that a bronchus is weakened by infection, it is by no means clear how the condition develops, but various factors seem to enter into its pathogenesis and mechanism. Of these, the most important are a weakening of the bronchial wall as a result of infection and raised intra-bronchial pressure. The bronchi dilate normally on inspiration, owing to the difference in pressure between the lumen of the bronchi and the thorax but they come back to normal again on expiration. Where bronchiectasis is occurring, the weakened bronchial wall causes a greater dilatation on inspiration, but, owing to the loss of elasticity of the wall, the return to a narrower lumen on expiration fails to occur. This is how gradually permanent, or pathological, dilatation takes place. It follows from this that anything that increases the negative pressure within the thorax will exert a greater dilating force on the bronchial walls, whether weakened by infection or not. This occurs in atelectasis of the lung, in which the negative pressure in the thorax becomes high, according as the condition occurs in patchy areas or in massive form. Both air vesicles and air tubes are equally exposed to the dilating force when present. In pure atelectatic bronchiectasis, there is usually diffuse cylindrical dilatation of the bronchi continuing to the pleura, with little or no involvement of the muscular and elastic tissue of the bronchial wall. Recent work on the pathogenesis of bronchiectasis emphasizes the rôle of atelectasis as the more important physical force which produces acquired bronchiectasis. [Andrus (1937), Lander and Davidson (1938)].

There are thus several factors which may operate in producing bronchiectasis—infection, obstruction (intra-bronchial and extra-bronchial) and atelectasis, to which may perhaps be added the traction of fibrosing inflammatory tissue around bronchi and bronchioles in various inflammations of the pulmonary parenchyma. Depending upon the extent, severity, and duration of the pathological processes, the dilated bronchial tubes assume different shapes—cylindrical (or tubular), fusiform, beaded, or saccular. A combination of these may be, and is often, present in the same case. Generally speaking, the cylindrical, fusiform, and beaded types result from an extensive, but comparatively mild, inflammation more or less limited to the bronchial walls, whereas the saccular type represents the end-stage of the process of necrosis with considerable fixed-tissue proliferation around, leading to subsequent abscess formation. Whatever the cause, the dilatations are nearly always surrounded by fibrous tissue, the cavities are lined with epithelium and the lower lobes of the lung are usually involved. The choice of

treatment depends a good deal on an appreciation of these factors.

The pulmonary circulation is not affected in the milder cases and in cases involving small areas, but in cases with advanced disease over wide areas and where there is much fibrosis, the right side of the heart may show evidence of dilatation. Absorption of septic material may lead to clubbing of the fingers and less commonly to hypertrophic pulmonary osteo-arthritis. In chronic cases, the absorption of toxins may lead to amyloid disease, albuminuria and enlargement of liver and spleen. Brain abscess from embolic infection may supervene as a fatal complication.

The following predisposing ætiological factors were elicited in 104 of our cases, no relevant information being available in the rest :—

Lobar pneumonia	..	48	cases
Influenza	..	10	"
Whooping cough and measles	..	7	"
Chronic bronchitis	..	6	"
Pleurisy	..	6	"
Following abscess of the lung	..	5	"
Asthma	..	4	"
Chronic malaria	..	4	"
Kala-azar (?)	..	4	"
Typhoid fever (?)	..	3	"
Dysentery (?)	..	3	"
Aspiration of foreign body	..	2	"
Tuberculosis of the lung	..	2	"
TOTAL	..	104	cases

The average period intervening between these illnesses and the first appearance of symptoms, as obtained from the statement of patients, was as follows :—the largest number gave it as 7 to 8 years, next 3 to 6 years, next 1 to 3 years, next 20 to 45 years, and lastly below one year.

It will be noticed that the history of aspiration of foreign body has been rarely obtained in our series. The workers of the ear, nose and throat department tell us that they have rarely seen aspiration sequelæ after tonsillectomy. Nasal sinus infection, especially of the maxillary sinus, however, is of frequent occurrence. Many of the cases of bronchiectasis with a history of 'cough and colds' since childhood arise from chronic suppuration from chronic sinusitis. It is thus an indirect factor in the causation of bronchiectasis, which gradually follows putrid bronchitis.

Some clinical features

Age incidence.—The following age incidence was obtained in our series :—

Years	Cases	Years	Cases
4 to 10	.. 2	36 to 40	.. 24
11 to 15	.. 6	41 to 45	.. 24
16 to 20	.. 16	46 to 50	.. 6
21 to 25	.. 22	51 to 60	.. 12
26 to 30	.. 23	Above 60	.. 2
31 to 35	.. 23		
		TOTAL	.. 160

Sex.—Of the total cases, males numbered 122 or nearly 76 per cent and females 38 or approximately 24 per cent.

Community and occupation.—Hindus numbered 108; Mahomedans 34; Indian Christians 8; Anglo-Indians 7 and Chinese 3.

The cases came chiefly from the non-industrial population. No special predilection for any occupation was noticed in the present series.

Provincial distribution.—The following distribution has been found in our series :—

Bengal 130, Behar 12, U. P. 5, Madras 5, Punjab 2, Bombay 2, Orissa 2, and Tippera State 2.

Out of the 130 cases from Bengal, 44 were from Calcutta, 40 from the neighbouring districts of 24-Parganas, Howrah and Hooghly and the remainder from 13 other districts, out of a total of 27 districts. No case was obtained from the hilly tracts in Darjeeling district and none from the neighbouring province of Assam. Probably the nearness of the investigating centre has accounted for over 50 per cent of the cases being drawn from Calcutta and the neighbouring districts. It is quite possible that, if a systematic search is made in outlying areas of the province, the incidence will be found to be much higher than it has been in the present investigation.

Radiographic and bronchographic types of bronchiectasis

1. *Congenital.*—Only two cases, probably of the cystic variety, were met with, one in a girl, aged 22 years, in whom the whole of the left lung was involved and the other in a man, aged 36 years, in whom the left lingual portion of the upper lobe and the lower lobes were involved. Both were symptomless and were accidentally discovered in the course of systematic physical examination for non-pulmonary complaints in 1933 and 1932, respectively. The former case is still symptomless and the latter has been lost sight of.

2. Acquired

A. Dry 14 cases
B. Septic or suppurative:—			
Cylindrical or tubular	..	15	"
Early fusiform	..	19	"
Banded	..	2	"
Fuso-saccular	..	21	"
Saccular	..	58	"
Mixed	..	21	"
Bronchiectatic abscess	..	8	"
C. Atelectatic	..	3	"

It will be noticed that we have not been able to detect atelectasis of the involved lung, except in three cases. Case 11 cited in this paper is one of them and is an example of septic bronchiectasis following massive atelectasis of the left lung in a girl of seven years, as a consequence of the aspiration of a piece of betel-nut three months before. It will be noticed that comparatively few of the cases came to us in the early stages and that the advanced cases were practically never detected as bronchiectasis in the earlier stages prior to their investigation in this department.

*Localization of acquired bronchiectasis**A. Unilateral:*

Right lung—

Upper zone	5 cases
Middle zone	8 "
Lower zone	26 "
Both middle and lower zones	10 "
Entire lung	1 case

TOTAL .. 50 cases

Left lung—

Upper zone	1 case
Middle zone	8 cases
Lower zone	41 "
Both middle and lower zones	17 "
Entire lung	2 "

TOTAL .. 69 cases

B. Bilateral:

Both lower zones	30 cases
Both middle and lower zones	5 "
Middle zone of one lung and the lower of other	3 "
Entire lung of one side and lower zone of the other side	1 case

TOTAL .. 39 cases

It will be noticed that the lower lobe is much more commonly involved than the upper zones, and that the left lower lobe is more frequently involved than the right. Left-sided involvement seems to be more frequent. It shows further the necessity of exploring both lungs roentgenologically, especially if radical surgery is to be considered. Some of the illustrative lesions are reproduced in plates XVI, XVII and XVIII in most cases both before and after lipiodol. The history and physical findings of these cases are given below:—

Case 1.—D. S., Hindu male, aged 36 years, teacher. No relevant previous history of chronic respiratory infection or catarrh. No symptoms; came to hospital for the treatment of chronic dysentery. Condition detected accidentally during a routine physical examination.

Physical signs—crackling râles in front and friction-râles at back of lower half of left chest.

Case 2.—S. C. K., Hindu male, 36 years.

No relevant previous history except malarial attacks off and on; slight cough, without expectoration, for three months; small repeated hæmoptyses in clots every day for ten days before examination. No abnormal physical signs.

Case 3.—N. B., Mohammedan male, 56 years.

Chronic cough for five years; slight hæmoptysis once two years ago; expectoration—2 oz. per diem.

Physical findings—persistent crackling râles at back of right lower lobe.

Case 4.—S. R. A., Mohammedan male, 40 years.

Three attacks of broncho-pneumonia (? left) during the last ten years; cough for six months; expectoration profuse; hæmoptysis in streaks once ten days ago.

Physical signs—persistent crackling râles below inferior angle of right scapula and a few over left lower lobe.

Case 5.—H., Mohammedan male, 40 years.

Chronic cough for ten years; expectoration scanty; dyspnoea on exertion.

Physical findings—crackling râles over left lower lobe at back.

Case 6.—Mrs. U. G., Hindu female, 20 years.

Pneumonia three years ago, bilateral; chronic cough since then; expectoration 8 oz. a day; hæmoptysis, a fortnight ago; slight fever for 15 days; dyspnoea on exertion.

Physical findings—scattered rhonchi over both lungs.

Case 7.—F. C. G., Hindu male, 35 years.

Cough and expectoration for seven years; slight hæmoptysis off and on for five years; slight occasional fever.

Physical findings—scattered rhonchi over both lungs.

Case 8.—Mrs. R. K., European female, 32 years.

Bronchitis and pneumonia bilateral at age of ten years; expectoration—one tumblerful in 24 hours; dyspnoea on exertion.

Physical findings—slight loss of resonance and crackling râles over both lower zones.

Case 9.—D. L., Hindu male, 16 years.

Cough and moderate expectoration for six months; recurrent small hæmoptyses during the same period; slight fever off and on.

Physical findings—crackling râles over right, middle and lower zones of chest.

Case 10.—B. M., Hindu male, 30 years.

Measles at age of 8, followed by chronic cough which has continued; expectoration, moderate; occasional slight fever; dyspnoea on exertion.

Physical findings—crackling râles and friction; râles over both lower lobes.

Case 11.—Miss R. B. M., Hindu female, 7 years.

Aspiration of a piece of betel-nut three months ago; following this, cough and dyspnoea appeared; expectoration moderate but foetid for last seven days; marked dyspnoea; fever, maximum 101°F.; just admitted into hospital for bronchoscopic inspection and drainage.

Physical findings—pulse 120, respiration 40 at time of examination; increased resonance and bronchial breathing over the upper zone of left chest, râles over lower zone; slight swelling of hands and feet.

Diagnosis

Symptoms.—The early clinical history of a case of bronchiectasis is often far from typical; in fact, it may be silent. The symptoms and physical signs will, no doubt, depend on (i) the position and type of dilatation and on the condition of the bronchi which may show very slight or early evidence of secondary inflammation producing no abnormal secretion, and (ii) the condition of the surrounding pulmonary parenchyma, which may be almost normal or show evidence of inflammation, fibrosis, atelectasis or thickened pleura.

The case-taking of a suspected case of bronchiectasis is very important and must be aimed at eliciting the history of possible ætiological factors since childhood. The onset may be acute, subacute or insidious, covering a period of 3 months to 20 years or more. The probable duration of symptoms, as obtained from the patients, was as follows:—less than one year = 23.7 per cent, 1 to 2 years = 35 per cent, 3 to 5 years = 12.5 per cent and 5 to 45 years = 28.8 per cent. The symptoms may be absent, slight or marked. In the absence of any symptoms referable to the chest, the condition may be discovered accidentally during a routine physical examination, as happened in one of our cases (case 1) who attended the hospital for the treatment of dysentery, or at *post-mortem* in patients dying of some other disease.

The patient may seek medical aid for chronic cough and expectoration, or for hæmoptysis, chest pain, fever, emaciation or dyspnoea. The cough, when present, may be slight or severe, intermittent or persistent. In cases with much secretion, the cough occurs when some secretion

has collected and often with change of posture. A history of persistent cough and recurrent attacks of pneumonia or bronchitis in the same lobe since childhood or some years is very suggestive of bronchiectasis. The presence of clubbed fingers in such a case is an additional point in favour of the condition. *Expectoration*, when present, may be slight (less than 5i), moderate (5i to 5vi) or profuse (above 5vi) in 24 hours. In advanced stages of bronchiectasis with abscesses, there is often a foetid odour in the copious sputum. In the latter types of case, there is often fever, progressive emaciation, shortness of breath, clubbed fingers, sallow skin and an unpleasant odour in the breath. *Hæmoptysis* in small or large quantities may also occur. The copious sputum in suppurative types of bronchiectasis often separates into three layers on standing—an upper frothy layer, middle liquid layer and the lowermost of granular debris. Sputum examination gives persistently negative results for tubercle bacilli. Three per cent of our cases had no cough, 6 per cent had 'dry' cough and the remaining 91 per cent had cough with expectoration. Thirty-one per cent had scanty expectoration, 41 per cent moderate expectoration, 19 per cent profuse expectoration and 9 per cent had no expectoration. 17.5 per cent of the cases had foetid sputum. Twenty per cent of the patients complained of *chest pain* of some sort, 27.5 per cent had *fever* ranging between 99° to 100°F. (oral), 25 per cent gave history of some *loss of weight* and 11.5 per cent complained of *dyspnoea*. Fourteen per cent of the cases exhibited clubbed fingers.

Hæmoptysis, which is more frequent in bronchiectasis than in pulmonary tuberculosis, occurs in varying quantities. It may be the only symptom in a case or the sputum may be blood-tinged owing to mucosal congestion. Repeated hæmoptysis, at varying intervals, without any cough or sputum, may occur in 'dry' bronchiectasis. Seventy-nine per cent of our cases gave a history of hæmoptysis, 25.5 per cent of whom had a single hæmoptysis and 53.5 per cent recurrent hæmoptyses. Nineteen per cent of the cases had moderate to large hæmoptysis.

Physical signs.—On physical examination, the signs in the chest may be very varied. They may be absent or slight, or there may be only some retraction, limitation of movement and impaired percussion note, owing to fibrosis, over the area. The commonest finding, however, in moderately developed cases is medium 'crackling' râles at the end of inspiration in the lower third of the chest. This finding, along with a history of recurrent attacks of bronchitis, influenza or pneumonia in the lower third of the lung, is very suggestive. In more advanced cases, the râles may be coarse in character and, after coughing out of the sputum or after postural drainage, bronchial breathing or bronchophony may be elicited. In 6.3 per cent of our cases we had a type of biphasic creaking râles, called 'friction-râles', possessing the

characteristic quality of neither but some of both. This is almost pathognomonic of bronchiectasis. Clubbing of fingers, which is present in cases having defective drainage of the sputum, was noticed in 14 per cent of cases. The Wassermann reaction, which was done as a routine measure, was positive in 2.5 per cent of cases.

In some cases of lobar atelectatic bronchiectasis of the lower lobe, a triangular area may be mapped out alongside the vertebral column over which there is diminished resonance, bronchial breathing, increased whispered voice and medium râles. This type was noticed only in three cases. The incidence of the different signs elicited by us was as follows:—retraction of the chest wall on the affected side—5 per cent cases, comparative loss of resonance—2 per cent, diminished air entry—22.5 per cent, localized 'crackling' râles—37.5 per cent, localized 'friction râles'—6.3 per cent, bronchial breathing—5 per cent and no significant physical signs—8.7 per cent.

Sputum examination.—The examination of the sputum is important. If the quantity of sputum exceeds one ounce in 24 hours and if tubercle bacilli are not found on three consecutive examinations or by the concentration method, it should lead us to suspect bronchiectasis. Where the sputum is foetid, a search should be made, on gram-stained slides, for the presence of fuso-spirillar associations or other anaerobes.

Radiographical examination.—The next step in the procedure of investigation will be a fluoroscopic examination and radiography of the chest. Fluoroscopic examination helps us to detect if there is any fixation of the diaphragm (a very suggestive symptom) or if there is any area of ling in the lower part which shows increased detail. The radiograph may show areas which do not look like parenchymal infiltration but rather areas or bands of fibrosis or diffuse irregular haziness often extending from the hilum. In some of the advanced saccular types, appearances suggestive of thin-walled cavities may be present. The above radiographic findings, in the presence of a suggestive history and physical signs, are an indication for lipiodol bronchography, which coats the walls of the bronchi with the radio-opaque iodized oil and gives us an idea of the character and extent of involvement. In the meantime, an examination of the nasal sinuses, including radiography, should be done.

Lipiodol bronchography.—Before, however, lipiodol bronchography is done, every patient having expectoration should be postured with a view to emptying the cavities or tubes as far as possible. If possible, an inspection through the bronchoscope (or bronchial speculum) should be made to rule out the presence of stricture, neoplasm, foreign body or any congenital abnormality of the bronchi and to find out the condition of the mucous membrane of the bronchi, whether œdematous, purulent or

occluded. In case the latter condition is found, it is better to clear the tubes by aspiration in order to facilitate a more complete introduction of lipiodol into the affected bronchial tubes and saccules. Bronchoscopic examination was done in 76 of our cases and aspiration was carried out in 64 of them. In cases where the administration of autogenous vaccines from the secretions is desired, one can use the material from the end of the bronchoscope for culture. If the instillation of antiseptics into the cavities is desired, one can also introduce them through the bronchoscope. Gomenol (10 per cent—5 to 10 c.cm.) has thus been introduced in 50 of our cases.

In lipiodol bronchography, care should be taken to introduce the oil into the right portions of the lung, one at a time, by suitable adjustment of the position of the body of the patient, laterally, forward and backward and to have the skiagraph taken within three minutes of its introduction; otherwise the lipiodol reaches the alveoli and produces a blurred picture, vitiating the accuracy of the findings. Both lungs should be examined separately, including antero-posterior views, at an interval of 8 to 10 days. This is particularly important in case lobectomy is to be advised. After bronchography, the outlines and position of the dilated bronchi at once become evident and the diagnosis is clinched.

No serious accidents were encountered during or after lipiodol introduction. Three patients showed iodism and one had slight surgical emphysema around the site of injection.

Prognosis

Although one must admit that acquired bronchiectasis is a progressive disease and that, whatever the type of bronchiectasis—dry, cylindrical, or fusiform—it ultimately spreads, the gradual tendency being for tubular types to be transformed into fusiform and fusiform types to saccular, yet one meets with cases which have remained stationary over long periods or have even retrogressed. But it is usually difficult to foretell, in a given case, the course and outcome of the disease.

The prognosis is good in a case where the bronchus is dilated, but there is little or no abnormal secretion, and where the surrounding pulmonary parenchyma is relatively normal. The course in such cases may be quite long, 10 to 20 to 40 years, with very slight exacerbations. But, if each attack increases the extent of the disease, the patient may die eventually of broncho-pneumonia or intercurrent disease. There are some cases, on the other hand, which are rapidly progressive and where death takes place within a few years, if left untreated.

In judging about prognosis in Indian patients, it must be remembered that bronchiectasis is not probably so common and the exacerbations so frequent in the warmer tracts of India as it is in temperate climates. We have not yet been able to complete the follow-up of all cases and,

therefore, might be excused for citing the figures of Roles and Todd (1933). These authors based their conclusions on 106 cases of established bronchiectasis followed up over a period of three to six years in England. They grouped their cases into three classes: (1) dry type, which had recurrent hæmoptysis but no sputum, (2) cases with occasional sputum, and (3) fœtid cases in which copious foul sputum was a marked feature. Ten of the total of 14 cases in the first group, which is thought to be relatively benign, became infected within six years, three were dead and two totally incapacitated. The second group of cases were shown to have as bad a prognosis as the persistently septic or third group. These authors concluded that bronchiectasis in patients receiving medical treatment alone was an extremely fatal disease, as out of the 49 patients 23 were dead and nine were totally incapacitated, and of the remainder only four were 'dry' five years after the diagnosis was made—or a primary mortality of 47 per cent. They further showed that 18 of the 19 patients with septic bronchiectasis, who were treated by surgical methods, were quite well at the time of compiling the figures.

Owing to the great advances made in the surgical treatment of bronchiectasis, particularly by lobectomy in well-selected cases within the last few years, our ideas about the prognosis of a case has been considerably altered. In a recent series of 199 cases, operated on by Edwards (1939), the following mortality rate, according to age, was found:—

Four to 16 years—nil; 16 to 20 years—9.5 per cent; 20 to 30 years—14 per cent; 30 to 40 years—15 per cent; 40 to 50 years—31 per cent and above 50 years—nil.

The cure of a case depends on the correct localization of the changes and on a complete removal of the affected bronchi. A lower operative mortality is directly proportional to the type and extent of disease; the larger the area involved, the higher the mortality. The average mortality, which was 20 to 30 per cent some years ago, has been brought down to 5 to 10 per cent by improvements in the technique of operation and in careful pre-operative preparation and post-operative management.

Prophylaxis

From the figures supplied by us, it will appear that bronchiectasis is quite a common condition met with in the chest clinics in this country. Since the radical treatment of a well-established case of bronchiectasis requires a serious operation by surgeons possessing a high degree of technical skill and since such surgeons are not plentiful in India yet, it should be our aim to detect the condition at the earliest appearance of suspicious symptoms and before serious damage has been done. The public and especially parents should be told of the possible ætiological factors and to have all cases of chronic cough, for which no other cause is found,

thoroughly investigated, including the teeth, tonsils, and nasal sinuses. On the earliest appearance of symptoms in incipient cases, the patients may also be advised to effect a permanent change of domicile to a dry climate, which benefits the sinusitis as well.

Treatment

The treatment of bronchiectasis depends on the clinical type, on the extent of disease and its localization and on the nature of the infection.

The *congenital types* do not require any treatment unless there are symptoms. In *acquired types*, our aim should be to secure an early detection of the pathological condition and to prevent an extension of the disease by removing possible foci of infection in the upper respiratory tract and by measures aimed at improving the resistance to infection, such as living in a dust-free dry climate, taking a high-calorie and high-vitamin diet, heliotherapy, and the administration of autogenous vaccines. Autogenous vaccines were administered in 84 cases of our series. We cannot say that we obtained any striking benefit in many cases.

In cases of 'dry' hæmorrhagic bronchiectasis, if the hæmoptysis is small, no special treatment is required. If it is large and recurrent and if the exact localization has been determined, one has to advise lobectomy if radical treatment is desired.

In cases with troublesome cough, sedatives, which diminish the ciliary action within the bronchi, *i.e.*, the cough reflex, should be withheld. In comparatively early cases with expectoration, a planned programme of emptying the bronchial tubes of retained secretion by postural or bronchoscopic (suction) drainage should be carried out. Cough and sputum and toxæmia considerably disappear as a result of these procedures. They also decrease the chances of spread to other areas in the lung. Where fusospirillar associations are detected (42 cases in our series), we have given a course of solusvarsan or sulfarsenol injections with benefit.

If the disease is of long duration, before we give a decision as regards effective treatment we have to consider the type and extent of disease and to balance the risks of non-treatment and the probable results of palliative and radical operative treatment. The older the pulmonary infection, the less does it respond to conservative treatment.

Among *palliative measures*, the comparative advantages of bronchial drainage and collapse therapy may be considered.

In *postural drainage*, which is applicable to non-obstructive bronchiectasis, the patient lies on the side opposite to that of the basal bronchiectasis, leans over the side of the bed with the head almost touching the floor, so that the diseased side of the chest stands uppermost and higher than the neck and head. A special postural bed or table facilitates the procedure.

This position is maintained, at first from two to ten minutes, morning and evening, and gradually lengthened to half to one hour to completely empty the accumulated secretions. A patient can assume this position, with practice, for several hours daily without discomfort. In severe cases, it may be necessary to repeat the procedure several times daily and lengthen the interval as improvement sets in.

Where, however, an obstruction from congestion, œdema, granulation or otherwise is suspected or found, or where postural drainage, especially in bilateral cases, does not suffice, *bronchoscopic* (suction) *drainage* helps in effecting a considerable symptomatic improvement by relieving stagnation of secretions and sœtor, although the bronchial dilatation remains unchanged. If the obstruction is due to excessive granulations, their cauterization may re-establish the drainage. In cases with œdema of the bronchial mucous membrane, Samson (1938) advises spraying the area, through the bronchoscope, with a solution containing equal parts of 10 per cent cocaine and 5 per cent ephedrine, which has been found to help in the shrinkage of the mucosa and consequent improvement of drainage. A definite programme of bronchoscopic aspiration should be drawn up, say four to six aspirations at intervals of seven to ten days. If there is no clinical and roentgenological improvement within this period, further aspirations may be abandoned except during acute exacerbations. During the intervals between the bronchoscopic aspirations, daily postural drainage should be continued. In a large majority of cases, a great amelioration of symptoms takes place from drainage by these combined methods and lasts for quite a long time, *i.e.*, as long as the drainage is effective.

Bronchoscopy is, however, contra-indicated in aortic aneurysm, extensive laryngeal disease, cardiac infarction, cerebral embolism or thrombosis, hæmorrhage from bronchiectatic abscesses and marked hypertension and advanced cardiac failure.

Collapse therapy.—The choice of a method of surgical treatment requires much care and consideration. The object of collapse therapy is to keep the cavities empty and to prevent retention of secretions by reducing the size of or obliterating the dilated bronchi and also to put the diseased parenchyma at rest. Although the size of the dilatations may be decreased by the various procedures, there is very little evidence that the epithelium-lined bronchiectatic cavities are ever obliterated or return to normal size.

Phrenic crush or artificial pneumothorax might be considered as a possible procedure for incipient, unilateral, lower lobe cases but we have not been very happy with these methods. In case of pneumothorax, it has to be kept up for the rest of the patient's life, which is an obvious disadvantage. As regards paralysis of the diaphragm, admitting that it may help to alter the direction of the vertically-situated

dilated bronchi to a more horizontal position, it has the disadvantage of interfering with the cough-reflex which helps us to cough out the bronchial secretions. Although in isolated cases they have shown some benefit, the results in general are unsatisfactory. Although thoracoplasty has done undoubted good in some strictly unilateral cases where the whole lung has been involved, it fails in well-developed cases containing epithelium-lined cavities. Hence, the end-results are seldom good, as the diseased tissues do not disappear. In selected cases where the more radical procedure is not possible, thoracoplasty may be advised. Postural drainage must, however, precede and follow all these collapse-therapy procedures.

The field for radical or curative treatment

The only really effective treatment of bronchiectasis is to remove the diseased area entirely. It is very necessary for this purpose to determine how much of the area is actually diseased and whether the other lung is totally or practically free from infection and dilatation, as the operative mortality in bilateral cases of any degree of severity is very high. Although no case in the present series has been treated by lobectomy, it will be seen that, for various reasons and because patients do not come to us in comparatively early stages when the disease is limited, the field for this operation in this country is rather limited. We hope to be able to report the results of this operation in a subsequent paper.

The pre-operative preparation of the patient is important. Before deciding on the operation, it is assumed that both lungs have been thoroughly investigated by lipiodol bronchography, the apparently normal side being taken up first. We should prefer to select a case where the unilobar saccular bronchiectasis is limited to the lower lobe, where the extent of disease and general toxæmia are minimal, and where the general condition of the patient is good. Having selected such a case, our first step will be to eliminate all sources of infection in the upper respiratory passages. Next, an attempt should be made to drain the bronchial secretion by postural and bronchoscopic drainage for some weeks previous to the operation.

So far as the operation is concerned, two methods are open to us for consideration:—

1. *Cautery pneumonectomy* (Graham, 1925), applicable to chronic multilobar abscesses peripherally situated and practically confined to one lobe of the lung. The operative mortality of this procedure (11 to 20 per cent), which was at one time thought to be lower than lobectomy is not so now, as the operative mortality of the latter has been considerably brought down by recent improvements in technique (5 to 10 per cent).

2. *Lobectomy*, or the removal of an entire lobe of a lung. Edwards (1939) considers that patients between the ages of four and 40 years

(and exceptionally older) with bronchiectasis which is reasonably localized and infected and in whom there is no serious general contra-indication should be considered as candidates for radical excision of the portion of the lung affected'. But others seem to take a more cautious view. They are of the opinion that, in view of the fact that many patients who suffer from bronchiectasis for a long period do not suffer any disability from it, except cough and sputum and that they die of some inter-current disease, some definite disability, such as copious fœtid sputum and chronic ill-health from recurrent hæmoptysis, broncho-pneumonia or sepsis toxæmia must be present before such a serious operation as lobectomy is advised.

The operation of choice is the one-stage operation of Shenstone and Janes, preceded by 'pleural poudrage'. Edwards has recently published an excellent paper (1939) explaining this technique and the results of operation in 199 cases. He has shown that the earlier the age, i.e., the less chronic the disease, the less is the operative mortality. For example, in cases between four and 16 years there were no deaths in his series, between 16 and 20 years—9.5 per cent mortality, between 20 and 30 years—14 per cent, between 30 and 40 years—15 per cent and between 40 and 50 years—31 per cent. The successful post-operative management of a case is necessary to ensure a low operative mortality.

Conclusion

It has been shown that bronchiectasis is of fairly frequent occurrence in this country and that practically all types are met with. The authors believe that if a systematic search is made, as has been done in the present study, other provinces will be able to bring its frequent incidence to the surface. In the absence of an application of the proper diagnostic methods, many cases have in the past been wrongly diagnosed as pulmonary tuberculosis and have even been referred to sanatoria for treatment. It is hoped that such errors will become rarer and rarer as we progress with the study of this disease.

Due emphasis has been laid on the importance of prophylaxis and early detection of bronchiectasis, as it is a progressive disease not often amenable to palliative measures, and as the radical treatment carries definite risks and is only applicable to strictly unilateral cases.

Acknowledgments

The authors wish to express their gratitude to the staff of the oto-rhino-laryngology and the x-ray departments of the Medical College Hospitals for the ungrudging help and co-operation which they rendered to the present investigation.

COLLAPSE THERAPY OF PULMONARY TUBERCULOSIS

REPORT ON A SECOND SERIES OF 205 THORACOPLASTY OPERATIONS ON 91 PATIENTS FROM THE WANLESS TUBERCULOSIS SANATORIUM, WANLESSWADI, DISTRICT SATARA

By W. M. G. JONES, B.Sc., M.D.
Medical Superintendent

Introduction

At a time when the collapse therapy of pulmonary tuberculosis is well standardized in all western clinics, it is strange that so little of it is being done in India. Almost every issue of the *American Review of Tuberculosis*, of *Tubercle* or of the *Journal of Thoracic Surgery* has one or more articles on the good and permanent results of this form of therapy. Perhaps these excellent journals need introduction to the sanatoria of India. On this subject no one need be uninformed for long, when there are such excellent books as for example, John Alexander's

wonderful book (1937)—*The Collapse Therapy of Pulmonary Tuberculosis*—to guide him. If this teaching is considered too 'radical' by some of the medical profession in India, it must be because they are unacquainted with the work of others such as O'Brien, Coryllos, Morriston Davies, Sauerbruch and the host of surgeons in this field who have demonstrated past all doubt that collapse therapy is the conservative way to treat pulmonary tuberculosis. It gives the best results, and the lowest mortality; it saves many who would die without its help, and restores a large proportion of them to work.

In this article from the Wanless Tuberculosis Sanatorium, we wish to put before the medical profession in India the results of our experience with collapse therapy in the treatment of pulmonary tuberculosis. These are not 'experiments' with a few cases, but the routine application of the methods outlined in Alexander's book to the patients in our institution. The Wanless Tuberculosis Sanatorium has 150 beds. Of the approximately 200 people treated for more than three months last year (1938) there were about—

70 treated by pneumothorax (and internal pneumolysis),
40 treated by phrenic operations,
70 treated by thoracoplasty or similar operations,
10 treated by miscellaneous surgical measures, and
10 treated by non-surgical methods.

200

We have the experience of treating some 800 cases by these methods during the past five years. As the principles of collapse therapy by thoracoplasty in the treatment of pulmonary tuberculosis are apparently not well understood in this country, we shall discuss briefly first our method of application of this treatment, and then give the results of the surgical work done during the past 1½ years. We wish to stress the use and value of thoracoplasty in the treatment of pulmonary tuberculosis as we find that this method of treatment is insufficiently used in India; hence a very large body of tuberculous patients, especially pneumothorax failures, are left untreated and eventually die of their disease. In surgical collapse, we have a simple, effectual and safe remedy.

The application of collapse therapy

All unilateral and bilateral tuberculosis, whether cavity or not, is first given a trial of pneumothorax, unilateral or bilateral. As shown above, in only 35 per cent of cases is induction of pneumothorax possible. Ideally we believe each case should be kept in bed until the cavity is closed and the blood examinations (the Schilling count and sedimentation test) return to normal, but often this is not practicable. In a very large proportion of pneumothorax cases adhesions prevent an efficient collapse and in these cases internal pneumolysis should not be delayed long. There are dangers both ways, however, as we have seen adhesions

stretch and cavities close (where we had predicted this could not happen) and cavities have grown larger or caused spread of disease (where we thought there was no danger). Internal pneumolysis is generally such a small operation with so few complications and dangers that it is better to do it early. In this way a good 'selective collapse' (*i.e.*, a collapse that is best at the diseased area) is soon obtained. Thus complete abolition of the positive sputum is possible at an early date. This is, of course, the objective of the pneumothorax. The previously 'open' case (infectious to himself as well as to others) becomes a 'closed' case (infectious to no one) in a few months. With other workers in this field, we also deprecate the maintenance of a contra-selective collapse for long, for fear of contra-lateral spread and other complications, such as pleural effusion, etc. By this we do not mean to exclude a trial of several months of positive-pressure pneumothorax as this sometimes changes a poor pneumothorax into a good one.

Phrenic nerve paralysis is also of great value as a supplement to artificial pneumothorax where non-operable adhesions are preventing satisfactory collapse, as a stabilizer in successful pneumothorax to lengthen the refilling interval, and to provide a margin of safety for the patient in case the compression by pneumothorax be lost later.

When pneumothorax is found impossible, or though possible has failed to be 'selective' in type despite a fair trial, it is abandoned and then a phrenic nerve crushing is usually advised. The patient is also kept on strict bed rest, and these two measures give the lung a few months' time for absorption of exudative elements, disappearance of fever, gain in weight, and reduction in the size of the cavity or lesion if that is possible (*see plate XIX, case 3, a, b and c*).

We should note, however, that the mild 'relaxation' produced by diaphragmatic paralysis cannot benefit old chronic cases with much fibrosis, emphysema, or large cavities. These cases need no 'preparation' for thoracoplasty, but one must remember their chronicity in almost direct proportion diminishes the chances of successful collapse. It is for this reason that thoracoplasty used as a 'last resort' is likely to be a failure. Like all other methods of treatment it must be used in suitable cases and at the optimum time. But the postponement of major surgery in these pneumothorax failures, until exudative elements have absorbed and the case has become more 'stable', as well as afebrile, is a most important point, and has a great deal to do with a low percentage of post-operative reactions. Furthermore, a few cases will show such surprising improvement on this simple regime of rest that thoracoplasty may not be necessary.

It is frequently stated in the literature that benefit from phrenic surgery is proportional to

the amount of diaphragmatic rise. While there is truth in this statement, we believe that the most important element in the production of a good result is the character of the lesion itself. How often one sees a good effect and cavity closure when the diaphragmatic rise is hardly appreciable, or only moderate! In these cases it is very likely that the 'clearing' of the lesions, and contraction of cavities, is due to the intrinsic character of the lesion, which lacks fibrous elements and dense infiltration, and not entirely to the phrenic surgery. Indeed spontaneous improvement is also frequently seen in cases which have not had any surgery, and it is for this reason that diaphragmatic paralysis is only considered as a 'help' to the active treatment, namely, the rest in bed (*see plate XIX, case 1*).

Each one of these unilateral cases (and many of the bilateral ones too), especially those with definite cavitation, is a potential thoracoplasty case as soon as the pneumothorax is known to be a failure. Except in those cases where the rise of the diaphragm is great and/or the x-ray clearing unusual, diaphragmatic paralysis is not a satisfactory substitute for good selective collapse, which can be obtained so readily by pneumothorax or thoracoplasty. On the other hand, a few months of temporary diaphragmatic rest is most helpful in preparing these patients for thoracoplasty. Hence, in accord with the practice of most western clinics we use only a crushing of the phrenic nerve at this stage. In this way the patient secures a return of diaphragmatic function—and so of basal lung function—about the time that the collapse therapy is completed. If this is quite successful, the return of diaphragmatic function is welcomed. If a further six months' paralysis seems advisable, re-crushing is done. In bilateral cases with very low vital capacity further surgical collapse may occasionally have to await the return of diaphragmatic function. Likewise an excessive diaphragmatic rise may produce dyspnoea. A permanent phrenic interruption (by avulsion of the nerve) carries this danger, that it may disable the patient without accomplishing cavity closure. These cases are hopeless when cross infection in the good lung occurs. Avulsions should be limited to basal cases; or used only when the case is quite stable and cross infection unlikely.

In bilateral cases there need be no hesitation in controlling the area of fresh disease on the good side with a small selective pneumothorax. In our series, a number of such cases have gone through repeated thoracoplasties on the other side without a spread of disease or untoward reactions. In bilateral cases, when bilateral pneumothorax fails, the decision as to which side should have a diaphragmatic paralysis (or whether both sides) may be very difficult. Usually the wisest decision is to leave both diaphragms alone. If the disease is restricted to both apices, a bilateral collapse may be possible.

In favourable cases (which means the great majority of treatable cases), three to five months after admission to the sanatorium either the pneumothorax is well established (with cavity closure and negative sputum) and the patient is out of danger himself and is no danger to his associates, or after phrenic crushing and strict rest in bed the lesion or cavity has shown a sufficient improvement to justify continuing this line of treatment; or the case is afebrile and sufficiently stabilized by rest in bed and temporary diaphragmatic paralysis for thoracoplasty. Naturally some cases are not ready for major surgery in such a short time, while others are ready sooner. Every case is decided on its own merits. The rule is to defer further surgery as long as the x-ray shows progressive clearing of exudative elements and/or there is steady reduction in the size of the lesion or of the cavity. The presence of fever is not an absolute contraindication to operation unless it indicates active disease in the lungs or abdomen; nevertheless, we do not like to have to operate on febrile cases who seldom do well. In general we may say that any afebrile case, chiefly or entirely unilateral, whose general condition is good, is a candidate for thoracoplasty; and the chances of obtaining a good result by this means are above 75 per cent, and of returning to work about 50 per cent.

Doctors in charge of other sanatoria may say: 'We do not see many cases suitable for thoracoplasty'. But we maintain that *any* unilateral case of tuberculosis with positive sputum and open cavity is suitable for surgical collapse after pneumothorax (and phrenic interruption in certain cases) has failed to heal the lesion. These are the common cases we all see by the hundreds and that fill our wards and cottages. While the disease is unilateral collapse it, for when it becomes bilateral the dangers and difficulties are increased many times, if indeed cure is possible at all, *e.g.*, table A shows that the poor results in good and fairly good cases are 9 to 13 per cent, while in the poor cases (bad chronics) they are 53 per cent.

Dangers

But what are the dangers of a major operation like thoracoplasty on patients weakened by chronic disease? These are so small in experienced hands as to be almost negligible. Indeed, we have had as many 'spreads' of disease while waiting for surgery as we have had after surgery. To put it another way, the risk of the operation is about 5 per cent while the risks of disablement and death from untreated disease itself runs all the way up to 100 per cent! Witness the fact that of *all* sanatorium admissions more than 50 per cent are found to be absolutely hopeless. The statistics we are considering in this paper concern only the 50 per cent who remain for treatment*. Nevertheless, it is a

constant source of astonishment to us to see how much our chronically sick patients will stand. No, it is wrong to say 'how much', for one must never try to see 'how much' they will stand. Let us say 'how well' they stand a series of two or three thoracoplasty operations, but for good results these must be properly done and rightly spaced (*see* plate XIX, case 2).

Operation in stages

Thoracoplasty is major surgery, but not as some imagine it is. A few years ago thoracic surgeons attempted too much at one time with the result that most patients left the operating table in a state of considerable shock. Naturally the mortality was around 20 per cent and it took patients a long time to recover from the effects of such a big operation. One of the first thoracoplasties ever done was a removal at one sitting of all ribs from one side front and back, top to bottom! The patient lived and was exhibited everywhere. The ideal is to have little or no shock. To this end it has been found by vast experience that the operations must be done in multiple stages, two or two and a half ribs for each of the first two stages, and one or two ribs for the third stage. If more than this number are done the length of rib removed is reduced, and the next stage is an anterior approach (from the axilla or parasternal). Except in anterior stages, 10 per cent formalin is used on rib beds routinely to delay bone regeneration; it must be rubbed in well. Its omission will be regretted, as revision operations are far from easy and carry a higher mortality. All transverse processes except the first are also removed when increased collapse in the paravertebral area is desired.

The amount of rib removal necessary to secure adequate collapse of a lesion and closure of the cavity is a matter of experience, but in general the rule observed by all is to remove from above downward (*i.e.*, beginning with the first rib), all ribs which in the x-ray overlie the lesion, both front and back, *e.g.*, a cavity seen under the 4th and 5th ribs would require removal of 1 to 3 ribs in toto and the posterior halves of 4th to 7th. If the 7th rib is not included it is wise to trim off the end of the scapula so that the tip of this bone will not impinge on the 7th rib. This is a frequent cause of pain. Furthermore, collapse in the posterior half of the chest is much improved by having the scapula fit into the newly-made depression. The deformity produced by a good thoracoplasty is so little that when the clothes are worn the contour of the chest and shoulders is practically normal. Also the arm and shoulder regain complete function in nearly all cases.

The permanency of surgical collapse bothers some people. Will the compressed lung never function again? They overlook the fact that tuberculosis has already destroyed the function of the lung in the area involved, and where there is 'cavity' there is no lung tissue at all! When

*The Wanless Sanatorium receives all applicants for admission thereby keeping in its own hands the question of 'treatability'.

the reduction of lung function and destruction of lung tissue is minimal a temporary collapse is sufficient—and that we have in diaphragmatic paralysis or in pneumothorax, but even in these minimal cases, the collapse has to be maintained for 1 to 3 years to secure healing.

Notes on technique.—A first-stage thoracoplasty takes us a little over one hour from start to finish. This is somewhat longer than advocated by others, but apparently the patients suffer no harm thereby. Gentleness and good hæmostasis are of more value than speed. Ninety per cent of our major surgery is done by our staff doctors and not by one team or by one specialist as in western clinics. For anaesthesia we use morphine-atropine (or hyoscine), and ether-mixture under 10 pounds air pressure. (This new pressure etherizer is designed by Dr. C. M. Van-Allen and is manufactured by the N. Powell and Co., Bombay.) In this way even patients with a low vital capacity are assured of a good oxygen supply. This is a most important point in this kind of surgery. Some method of pressure anaesthesia is absolutely necessary, as, aside from the question of oxygen supply, a pressure system can overcome undue pulmonary 'flapping' when the lung is very mobile; prevent pulmonary collapse in the event of an open pneumothorax (from pleural tear, or in open pneumolysis); and last, but not the least, give the anaesthetist a positive means of controlling respiration (a pulmator in effect).

We have had five cases stop breathing on the operating table. All were resuscitated without touching the ribs merely by regulating the air pressure, and 'the operation completed as planned'.

We use a prone position on the operating table as it gives the lungs maximal freedom. The head is lowered about 15° to ensure drainage of sputum. Where the volume of daily expectoration is large, or in the presence of a bronchial fistula, local anaesthesia is to be preferred. In all weak patients saline is administered intravenously during the course of the operation. The surgeon must be prepared to remove fewer ribs than usual when the lung collapse is excessive; or to terminate the operation on the first sign of shock or falling blood pressure.

Post-operative care.—After operation the post-operative care is most important and the surgeon must be ready to attend the patient at all hours. Sufficient morphia to allay pain and permit cough, plenty (1,000 to 3,000 c.cm.) of intravenous fluids, tight bandages to prevent paradoxical motion, deep breathing (pressure breathing, viz, as employed during the 'pressure anaesthesia', to aerate the lungs and prevent atelectasis) when necessary, frequent expectoration and change of position, are the major points. The most important preventive measure is not to attempt too much on the operating table. The second and subsequent stages may be undertaken 3 to 6 weeks apart. After 8 weeks,

beginning fibrosis tends to limit the collapse even when formalin is used.

As the ordinary x-ray plate may not show up cavities buried in a partially-collapsed and atelectatic lung, it is an excellent practice to employ a double exposure technique for every x-ray taken after the first operative stage. (Some of our illustrations will demonstrate the results of this method, which gives the good side a normal exposure and the side operated upon an over-exposure.) A fresh x-ray must be taken before each operation, as it is indispensable in deciding the amount of rib to be removed, and noting the presence or absence of fresh areas of disease.

As soon as possible, after operation it is very essential that the patient be encouraged to learn to lie on the affected side with a small pillow tucked in the axilla; or to lie in a canvas sling on that side.

When the number of ribs required to secure adequate lung collapse have been removed (in 2 or 3 stages), the patient enters the second phase of his treatment, often the most trying, for it is *six months' strict rest in bed*. Some cases take *much more* than this. If the surgical collapse has been sufficiently well done, however, the patient is without symptoms, without fever, cough or sputum, and soon gains weight and strength. Frequently this does not begin until several months after the operations are completed, and healing is under way, but it does come if the disease is not too widespread in lung or abdomen; and provided that the effect of the operations has not been deleterious. Many a time, however, this is a trying period for both patient and surgeon for the long confinement to bed becomes irksome to many, as they do not understand the necessity for continued rest. Moreover, the collapse by x-ray may look satisfactory and no cavity may be visible, but the sputum may continue to be positive. The patient thinks, 'have I endured two or three operations in vain?'—the surgeon—'what should I do now?' Fortunately for both, in most instances nothing is necessary but continued bed-rest, and the sputum soon ceases entirely; but in a few cases another rib-resection, perhaps of anterior stumps, may be required. Bronchoscopy is revealing that many of the persistently-positive-sputum cases have tracheal lesions, but we have no experience along this line yet. In one case of posterior thoracoplasty we discovered a definite cavity under the sixth cartilage anteriorly. The sputum remained negative when this cavity was closed.

The reason why at least six months' bed rest is *strictly* enforced after collapse therapy is the evidence (from autopsies) that it takes at least six to eight months for a completely compressed tuberculous cavity to heal. Thereafter graduated walking exercises are carefully begun; and after another six months (one year after cavity closure by thoracoplasty) if all goes well, light

work may be permitted. The result of this conservative method of treatment is that very few well-collapsed cases relapse, in fact we can say, the relapses come almost entirely in those with a poor resistance, or incomplete collapse, or who have extensive disease in both lungs, or who refuse to follow advice and insist on a return to activity too soon. One of our cases with a good collapse at the right apex relapsed six months later after developing a sudden complete left basal atelectasis which produced such severe paradoxical breathing that he was extremely dyspnoeic for weeks. This state of affairs re-expanded the collapsed area, resulted in a relapse, and finally in death. Some of our early cases relapsed because we did not appreciate the necessity for complete cavity closure. Even a small 'innocent' cavity remnant may seed the whole lung in a few months.

Some cavities with rigid walls seem impossible to close by any means. Even the most extensive rib resection merely pushes the cavity into the yielding mediastinum, or (as in the Semb type thoracoplasty which completely immobilizes the lung apex) the cavity sinks down into the lung under protection of uncut lower ribs. Fortunately, these cases are not numerous. In a few such cases we have attempted closure of the residual cavity by plombage (paraffin filling) and have sometimes succeeded (see plate XIX, case 4). More frequently, no such extra-pleural space can be dissected. In that case external drainage is possible. In one of our first series we did this, with an ultimate good result.

Results of collapse surgery

To demonstrate what a large percentage of pneumothorax cases require adhesion cutting to secure selective collapse and negative sputum, our statistics show that out of approximately 110 pneumothorax cases in the past 18 months (June 1937 to January 1939) we have performed internal pneumolysis on 94 cases, as follows:—

17 cases where adhesions proved to be uncuttable,
36 cases whose adhesions could be partially severed,
and
41 cases whose adhesions could be entirely severed,
94

securing cavity closure in 47 of the 77 operable cases, or 61 per cent (method employed was thermal cautery). This means that 85 per cent of pneumothorax cases (about 30 per cent of all our cases) required an operation to make the pneumothorax effective.

Results of phrenic operations

A detailed study of our phrenic operations has not been made and therefore will not be reported on here. Two-thirds of all phrenic operations are done in connection with thoracoplasty or pneumothorax.

Thoracoplasty results

An earlier report (Jones, 1937) on 212 thoracoplasty operations on 110 patients showed 12.7 per cent dead, 25.5 per cent not improved or

worse, and 61.8 per cent benefited (21 cases improved, 16 very much improved and 26 apparently arrested; a total of 42 per cent much benefited). For comparison 2,642 thoracoplasty cases (unselected) reported by various thoracic surgeons in the West showed the following results:—

36-50 per cent	cured.
15-30	" improved.
14-25	" unimproved.
10-14	" dead.

Our results were encouraging to us, even if they did not appear very good on paper, for we were learning; and also we knew the tremendous risks we took in many of our cases. We never had an eye to statistics but offered surgery to any case if there seemed to be a chance of benefit. Frequently, the pressure to operate came from the relatives because 'operated cases get well quickly'.

At this time we are able to give a preliminary report on a further 205 thoracoplasties on 94 patients (covering the 1½-year period July 1937 to January 1939). Four patients took discharge against advice before the surgical work could be completed, reducing the report to 201 operations on 90 patients.

Dividing these into three groups—

Group I. Good	chronics	34 cases
" II. Slipping	"	24 "
" III. Bad	"	32 "
				90

The good results out of the whole 90 cases are 67 or 74.5 per cent. To show that these are not selected cases, 37 per cent (34 cases) of the 90 had bilateral pulmonary tuberculosis. Below we give a list of the complications found in the 32 patients in group 3 (the bad chronics).

Empyema	3 cases
Bilateral pulmonary disease	19 "
Abdominal tuberculosis	8 "
Huge cavities	3 "
Children	2 "
Bronchiectasis	2 "
Relapsed basal case (first series)	1 case

While in this worst group collapse therapy has given 47 per cent of good results, this group also contains 9 out of the 12 unimproved cases (or 75 per cent) and 8 out of the 11 deaths (73 per cent). If we consider only the 'good' and 'slipping' chronics the good results are 91 per cent and 87 per cent respectively, the worse unimproved 4 to 6 per cent and the dead 3 to 8 per cent.

It must be kept clearly in mind that these thoracoplasty results are on the pneumothorax and phrenic failures, very frequently cases that have been languishing 'quite incapacitated' for months on other 'treatment', or no treatment. The good pneumothorax and phrenic cases with a strong tendency to get well dropped out of this list at the beginning. Table A clearly demonstrates that failure to secure cure by either of these two simpler methods (pneumothorax and phrenic surgery) by no means materially lessens the chances of a cure by some other collapse

TABLE A

	GROUP I		GROUP II		GROUP III		ALL CASES	
	Good chronics		Slipping chronics		Bad chronics			
	Cases	Per cent	Cases	Per cent	Cases	Per cent	Cases	Per cent
Apparently arrested ..	29	85	12	50.0	10	31	51	56.7
Much improved ..	2	6	9*	37.5	5	16	16	17.8
Worse/unimproved ..	2	6	1	4.2	9	28	12	13.3
Dead ..	1	3	2	8.3	8	25	11	12.2
TOTAL ..	34	100	24	100.0	32	100	90	100.0

* Three of the nine still under treatment in the sanatorium.

Key.—‘Apparently arrested’ means without symptoms, in excellent condition, no or negative sputum, satisfactory x-ray, for a period of 4 to 6 months.

‘Much improved’ means without symptoms, in excellent condition, sputum may or may not be negative, x-ray may or may not show the source of the sputum, for a period of 4 to 6 months.

measure. Indeed, the ‘good chronics’ (which translated into our language now means ‘the good unilateral cases, as soon as pneumothorax is known to have failed’) have a far greater chance of cure by surgery than those ‘fortunate’ cases that ‘take pneumothorax’ for months on end! This is a bold statement! But many surgeons working in this field are coming to believe it. Statistics for foreign countries cannot be applied to India, yet even abroad with all facilities for proper maintenance of pneumothorax in every city, final statistics show only 40 per cent (some authors maintain only about 20 per cent) reach an actual cure. In India pneumothorax facilities are only just beginning. (We appreciate full well that this report of ours is a preliminary one as our cases have to remain well over a two-year period of time to attain a strict ‘cure’. We hope to report later on the ultimate results in these cases. To date, however, we know of no relapses among the apparently-arrested or much improved cases reported herewith.)

There were 10 early deaths and one late one. The causes of these early deaths are listed in table B.

Of the two cases dying directly as a result of operation, the exact cause of death is not known in one. The pleura was badly torn twice, one of these resulting in death. In two other cases, there was serious wound infection materially affecting the patient, but not resulting in death. These are included in the 13 per cent of the poor results. (Doubtless many or all of the 12 unimproved-worse group will die soon.)

In addition to thoracoplasty, other forms of collapse therapy are reserved for special cases. The reason for caution in their use is that each of these other methods carries some additional risk. Paraffin plombage, we have done 30 times with excellent results in about half the cases. The paraffin itself has caused us no trouble but twice an extensive hæmorrhage necessitated removal

of the filling; and in other cases cavity closure was not secured. The reason for this is obscure as the apex is well immobilized and compressed. Curiously also the ‘Semb type’ theracoplasty

TABLE B

Cause of death after thoracoplasty operation in this series

Deaths not due to the operation.	Tuberculosis empyema cases ..	2	7.7 per cent
	Contra-lateral spontaneous pneumothorax ..	1	
	Massive atelectasis of contra-lateral base; 6 months after operation ..	1	
	Progressive abdominal tuberculosis ..	3	
Deaths due to the operation.	Post-operative wound infection ..	1	4.4 per cent
	Death due to operation ..	2	
	Contra-lateral spread of disease ..	1	
Cases ..		11	12.1 per cent

operation which also immobilized the apex secures the same criticism, viz, migration of the cavity caudad. This operation is unnecessary for routine use, but may be reserved for certain cases with large cavities or very medially-placed ones. Lately, another variety of the same procedure has been advocated—extra-pleural pneumothorax. We have done seven such cases recently with very good results in five. One needs much experience however to give a correct judgment. Western phthisiologists are still in disagreement over the proper use of these special collapse measures. Thoracoplasty on the other hand is well standardized, its technique simple, and its results good. Our direct operative mortality of 4.4 per cent should have been less as two of the four deaths might perhaps have been avoided with greater care and skill.

Complications during Artificial Pneumothorax Therapy: Viswanathan

Conclusion

(1) Collapse therapy of pulmonary tuberculosis needs to be known and used in India more than it is at present. Its risks are small while it offers excellent chances of cure to that large group of cases that cannot benefit by pneumothorax or phrenic surgery. While its application is chiefly to unilateral cases, it can be used in conjunction with contra-lateral pneumothorax and phrenic interruption in many bilateral ones as well. For most if not all chronic cases collapse therapy offers the shortest road to cure, while a good proportion can be rehabilitated for work.

Appendix

Case 1.—R. S. Admitted in November 1937, extensive bilateral apical infiltrations, with a large cavity on each side (x-ray, upper). Bilateral pneumothorax failed. Left thoracoplasty done in 4 stages, February to July 1938. Concurrently with left cavity closure the right cavity also closed spontaneously, with complete clearing of the infiltration (x-ray, lower). Sputum became persistently negative in August 1938. Patient discharged from the sanatorium in good general condition, practically no cough, and excellent blood reports 10½ months after admission; classification 'apparently arrested'.

Case 2.—E. M. Admitted October 1936, with extensive disease in the whole left lung, multiple cavities at the apex, and a very badly damaged right lung as well. She was judged to be a more-or-less hopeless case, but insisted on staying for treatment (x-ray, upper). Both pneumothorax and internal pneumolysis failed to close the apical cavities. Two stage thoracoplasty done in April 1938, and the sputum became persistently negative in October, five months later. A severe wound infection delayed recovery for several months. The right side gradually cleared (x-ray, lower). Patient left the sanatorium without symptoms or sputum in March 1939. A complicating intestinal tuberculosis prevented any gain in weight.

Case 3.—Mrs. C. P. First admission in 1937. She spent 8 months in the sanatorium and was discharged with a satisfactory pneumothorax on the left side. Readmission 5½ months later with the pneumothorax space lost, the disease active, and x-ray evidence of beginning infiltration at the left hilum (x-ray a). Right phrenic nerve crushed in May 1937, resulting in an excellent contraction of the diseased upper lobe, but the sputum remained positive (x-ray b). Two stage thoracoplasty in August (x-ray c). Sputum became negative immediately. Weight gain 43 lb. Discharged 'apparently arrested' in March 1939 after a stay of 11 months.

Case 4.—D. S. G. Admitted in January 1938 with a contra-selective right pneumothorax, and active disease in the left lung (x-ray, upper). The pneumothorax was abandoned and the right phrenic nerve was crushed, but without any apparent benefit. Three stage thoracoplasty completed by the end of April, but the cavity only migrated into the mediastinum, and the sputum remained positive. Paraffin plumbage done towards the end of July with successful closure of the cavity (x-ray, lower, the paraffin does not show, but is evidenced by the prominence of the regenerated ribs just below the clavicle). Sputum became persistently negative in September. Discharged in October, a little too early for 'apparently arrested' classification, but his subsequent recovery has been uneventful. Weight gain 18 lb.

COMPLICATIONS DURING ARTIFICIAL PNEUMOTHORAX THERAPY

By R. VISWANATHAN, B.A., M.D., M.R.C.P. (Lond.),
T.D.D. (Wales)

Lecturer in Tuberculosis, Medical College, and
Medical Officer in charge of Tuberculosis Department,
Vizagapatam

THERE is no gainsaying the fact that artificial pneumothorax is the most potent weapon in the armamentarium of the phthisiologist, but, as in the case of other therapeutic measures, pneumothorax also is likely to be abused by enterprising young physicians who are liable to use it in season and out of season, and thereby bring this excellent instrument into undeserved disrepute. The writer was told by a touring medical officer, of how a doctor in a mofussil station boasted that he had induced pneumothorax in several cases without examining the patients radiographically, either before or after induction. Now that a great impetus is given to the problem of tuberculosis in this country there is every possibility of increasing the incidence of similar therapeutic adventures which are undoubtedly beset with positive danger. Hence a statistical study of the complications and dangers of pneumothorax therapy is justified at the present juncture. Woodcock (1915) wrote, 'there are dangers in connection with the production of artificial pneumothorax, but the greatest and about this there be no mistake is the neglect in which it is held'.

In a series of three hundred patients on whom pneumothorax was attempted, the complications* that occurred during primary induction and subsequent course of treatment are given as follows :—

Pleural effusion	106
Pain—severe .. 5½	22
" —slight .. 17½	
Surgical emphysema	16
Marked mediastinal displacement ..	15
Mediastinal hernia	12
Spontaneous pneumothorax	7
Dyspnoea	6
Obliterative pleurisy	5
Pleural shock	1
Puncture of big blood vessels (including the heart)	1

Gas embolism.—This is a very serious complication often causing sudden death, though fortunately extremely rare; though I have not met with a single case, a number have been reported in the literature. Air may enter the pulmonary veins and if the coronary vessel is occluded by bubbles sudden death is likely to occur. Convulsions, unconsciousness, transient blindness, local blanching of the skin, hemiparesis and transient paralysis are some of the symptoms liable to occur, depending upon the situation of the air embolus. Air might enter the circulation without causing any kind of untoward symptoms whatsoever.

* Gas embolism, sepsis and pneumo-peritonium did not occur.

Pleural shock.—This is an equally rare but equally dangerous catastrophe. Some writers have denied the existence of shock, claiming that the symptoms are due to embolism. There is no doubt that the symptoms are often similar in both conditions. The shock which occurred in the one case in the present series was comparatively mild. It happened just when the needle was taken out after a successful primary induction. The patient suddenly became unconscious with mild convulsive movements all over the body; the pulse became thready and feeble; the head was immediately lowered, and the patient regained consciousness in a minute. In one of Burrell's (1937) cases the patient gave a few gasps and died immediately after the needle was withdrawn.

Pain.—Provided local anæsthesia is perfect, the passage of the needle through the chest wall and the puncture of the pleura ought to be painless. In most cases the introduction of air causes varying amounts of discomfort, but actual pain in a severe form occurs particularly when there are extensive adhesions. Such severe pain occurred in cases lasting for a day or two. Severe pain occurred in five cases lasting for a day or two. Slight pain was complained of in 17 cases. A few patients with bands of adhesions have complained of a dragging pain in the chest, whenever the refills produced positive pressure.

Puncture of big blood vessels (including the heart).—This accident occurred in one patient with left-sided fibro-caseous disease with marked shrinking of the lung, and consequent displacement of the heart to the left. As soon as the needle was introduced blood rushed into the tube. The needle was immediately withdrawn and nothing untoward happened.

Dyspnœa.—That many patients complain of slight shortness of breath during pneumothorax treatment, stands to reason because the vital capacity of the lung is definitely diminished after any form of collapse therapy. It is surprising, however, how much collapse in both the lungs may occur with little or no dyspnœa.

Sudden severe dyspnœa might occur as a result of spontaneous pneumothorax being superimposed on artificial pneumothorax. High positive pressure in the pleural cavity or marked mediastinal displacement or mediastinal hernia may cause dyspnœa in some cases. In six cases of the series, dyspnœa occurred after every refill and was sufficiently severe to necessitate abandonment of pneumothorax altogether.

Sepsis.—Ordinary septic precautions ought to be enough to prevent any form of sepsis.

Surgical emphysema.—Escape of air into the chest wall through the puncture made in the parietal pleura is liable to occur, particularly after primary induction, as the stimulation to cough is greatest at that time. More so will be the case in patients already suffering from a severe cough. There is no harm in this complication as the air gets absorbed in a

few days. In one patient severe subcutaneous emphysema extending over the chest, neck and even the upper extremity occurred after a successful intrapleural pneumolysis. Radiographic examination the next day showed complete expansion of the lung. Emphysema however disappeared in 15 days.

Pneumo-peritonium.—This accident is possible when there is a high diaphragm or when the puncture is made too low. In no case did this happen in the present series. One patient, who attended the writer's department for refills after discharge from another hospital, said that during the last refill in that hospital no change in the manometric reading was found even after 800 c.cm. of air were put in, but she felt as if the upper abdomen was becoming bloated. The abdominal discomfort lasted for a few days. This was evidently a case of accidental pneumo-peritoneum.

Spontaneous pneumothorax.—During pneumothorax treatment more air might get into the pleural cavity directly from the lung, either as a result of laceration of the visceral pleura by the needle or as a result of a superficial lesion or cavity breaking through, after the pleural layers are separated, or due to rupture of an adhesion at its point of attachment to the lung and consequent laceration of the subjacent pulmonary parenchyma. Spontaneous pneumothorax occurred in seven patients in the present series. In one case the accident happened after the third refill. Two hours after the refill the patient complained of severe pain and dyspnœa. Examination revealed marked displacement of the heart to the opposite side. Spontaneous pneumothorax was diagnosed and 800 c.cm. of air were aspirated leaving the manometric reading at $-7 -2$. In three hours' time his dyspnœa became worse and a valvular type of spontaneous rupture was diagnosed and a continuous drainage was put in. Pyo-pneumothorax occurred after the seventh refill. Even though pyo-pneumothorax resulted the patient lived for another year. In the first case the complication was due to rupture of a superficial cavity, while in the second case it must have resulted from the rupture of an adhesion. Nothing untoward happened in the remaining five cases, evidently on account of spontaneous closure of the openings in the lung.

Mediastinal hernia.—There are three weak spots in the mediastinum, in which only loose connective tissue separates the parietal pleura of the two sides. They are (1) in the anterior mediastinum behind the sternum, extending from the first to the third rib, (2) in the lower posterior mediastinum between the aorta posteriorly and œsophagus anteriorly, and (3) in the upper posterior mediastinum between the vertebræ posteriorly and œsophagus anteriorly. Mediastinal herniæ have been observed in each of these three places during the course of pneumothorax treatment. This subject has been well presented by Packard (1927), Doub and Jones (1937),

and others. Herniation occurred in 12 cases in the present series. The diagnosis was made only by radiographical examination as no untoward symptoms were noticed pertaining to this complication. Only one patient, in whom positive pressure was produced during a refill, complained of substernal pain and slight dyspnoea. The symptoms disappeared after two days, evidently because of absorption of air and consequent lowering of pressure in the pleural cavity, resulting in the disappearance of the hernia.

Marked mediastinal displacement.—In 15 cases the mediastinum was found to be markedly displaced even though negative pressure was maintained in the pleural cavity. Most of the cases were young adults who had either early or moderate lesions. In the majority of cases of chronic phthisis the mediastinum gets fixed probably on account of mediastinal pleuritis, but in some cases it is very mobile, and hence gets displaced even when the intrapleural pressure is negative. No untoward symptoms were noticed consequent on mediastinal displacement in these 15 cases, in whom the treatment was pursued successfully.

Pleural effusion.—Effusion during pneumothorax treatment has been the subject of extensive study by various writers. The incidence of effusion given by different people varies from 35 per cent to 90 per cent. In Burrell's (1937) 309 cases effusion developed in 128. Nicklas *et al.* (1937) assess the incidence at 67.5 per cent. In the present series out of the 204 cases in which the treatment was successfully continued, 106 developed effusion of varying degree, giving a percentage of 49.3. Massive effusion occurred in seven cases. The effusion turned out to be purulent in four cases two of them being the result of spontaneous pneumothorax. In some cases the onset of effusion is accompanied by constitutional disturbances such as a rise in temperature, acceleration of the pulse and loss of weight. Nicklas *et al.* (1937) divide effusions into hot effusions and cold effusions according as they are associated with febrile reaction or not.

Pleural effusion is the most common complication of artificial pneumothorax. Various explanations have been offered for its frequency; repeated trauma of the parietal pleura, irritation by the gas which acts as a foreign body, and interpleural pressure are a few of the theories. Pisani and Smejkal (1934) consider that effusion is due to the increased permeability of the capillaries from want of oxygen, to increased osmosis, to high concentration of hydrogen ions, to calcium deficiency, and, lastly, to the aspirating effect of a negative pressure. Whatever be the cause of the effusion it does not affect the prognosis adversely in the vast majority of cases. Purulent effusions are really dangerous. Obliterative pleuritis which might result from effusion in some cases will prevent further continuance of pneumothorax treatment.

THE COMPARATIVE VALUE OF DIFFERENT GOLD PREPARATIONS IN THE TREATMENT OF PULMONARY TUBERCULOSIS

By Y. G. SHRIKHANDE, B.Sc., M.B., B.S., T.D.D. (Wales)
Medical Superintendent, King Edward VII Sanatorium,
Bhowali, U. P.

GOLD has been used in the treatment of tuberculosis from time immemorial. Reference to it is found in the Vedas and the two great physicians, Charak and Sushruta, have advocated its use in their books. Even to-day, it is used by Ayurvedic physicians in different forms. The introduction of gold in the treatment of tuberculosis according to the western system of medicine may, however, be said to date from the time of Koch's investigations on the tubercle bacillus.

Until about the year 1916, experiments with gold were carried out with inorganic compounds. Attempts were later made to prepare effective organic compounds and the first to be prepared by Adolf Feldt was aurocantan. Certain disagreeable complications were, however, produced by it in a number of cases and this was attributed to the combination of gold with the cyanide group. Another compound was therefore prepared under the name krysolgan in which the metal was attached to the amino group. Krysolgan was followed by other preparations like solganal, solganal-B, lopion, etc.

While a good deal of literature continues to appear in the medical press for and against the use of gold, the fact that it is still being employed in several countries after a trial of many years is sufficient reason for believing in its efficacy in suitable cases, and it would not be considered unreasonable to say that gold as a

(Continued from previous column)

Obliterative pleuritis.—This complication might arise in the form of insidious and inexorable chronic dry pleurisy or as a result of pleural effusion, during the course of its absorption. In the present series, it occurred in five cases within six months after primary induction. This obliterative process is desirable at the termination of treatment by pneumothorax, but, if it happens during the course of active treatment, pneumothorax will have perforce to be abandoned.

remedy has come to stay in the treatment of pulmonary tuberculosis.

During recent years the market has been flooded with a variety of gold preparations and the medical man in general practice naturally finds it difficult to decide which preparation is most suitable or safe for use, and our opinion has on several occasions been sought for guidance.

Roughly speaking the different preparations of gold may be divided into three groups :—

- (1) Compounds soluble in water.
- (2) Compounds soluble in oil.
- (3) Insoluble compounds in oily suspension.

While it is true that many preparations have been placed on the market as a business proposition, in the case of some of the important ones an attempt has been made to reduce their toxic effects and increase their therapeutic value.

We have had the opportunity of using various gold preparations, such as krysolgan, triphal, lopion, sanocrysin, solganal, solganal-B, crisalbine, lypocrysol, myocrysin, oleo-sanocrysin, auro-protasin, solganal-B oleosum, etc. Sanocrysin and crisalbine are the same compound of sodium thiosulphate prepared by two firms under different names. Recently an oily suspension of a gold compound called 'K. G. 23' was sent to us for trial by the Indian Institute of Science at Bangalore.

Since 1926, nearly 1,000 cases of pulmonary tuberculosis have been treated in the sanatorium with the different preparations of gold and experience has shown that the choice at the present moment lies between sanocrysin and solganal. The former is an inorganic compound prepared by Möllgaard of Denmark and the latter is an inorganic compound prepared by Feldt of Germany.

The treatment of several cases with sanocrysin and solganal had left an impression in our minds that solganal was a much safer preparation, because while it produced equally good, if not better results, the complications with it were much less marked and much less dangerous.

Recently, however, I had the opportunity of reading the views of Frimodt-Möller and Barton (1938) on the comparative merits of sanocrysin and solganal and their opinion that 'sanocrysin had a much better therapeutic effect than solganal, while there is very little difference between the drugs as regards dangerous complication' set me thinking and I, therefore, wanted to make sure if our opinion about the two drugs, mentioned above, was correct.

Sanocrysin has been used in the sanatorium since 1926 and solganal was introduced for the first time in 1931. On going through the reports for 1931 and subsequent years it was found that sanocrysin was gradually being replaced by

solganal as will be evident from the following figures :—

Year	SANOCRYSIN		SOLGANAL ¹	
	Sanocrysin	Oleo-sanocrysin	Solganal	Solganal-B oleosum
1931 ..	17	..	23	..
1932 ..	28	..	17	..
1933 ..	35	..	6	21
1934 ..	1	8	..	47
1935	10	..	52
1936	88

For the purposes of this article, however, the cases treated during the year 1933 have been studied in detail and the conclusion has been drawn from them. The indications for treatment were the same whether the preparation used was sanocrysin or solganal, and no attempt was made to select patients for treatment with a particular preparation. Only those cases which received more than two injections have been taken into consideration.

Thirty-three cases were treated with sanocrysin and 20 cases with solganal and they were spread in the three stages of Turban-Gerhardt classification as follows :—

Stages	SANOCRYSIN		SOLGANAL	
	Number	Per cent	Number	Per cent
T1 ..	10	30.3	8	40
T2 ..	10	30.3	8	40
T3 ..	23	69.9	12	60

In judging the results of treatment in the two groups the following factors were taken into consideration :—

- (1) Effect on temperature.
- (2) Effect on weight.
- (3) Effect on tubercle bacilli.
- (4) Effect on blood sedimentation rate.
- (5) Effect on skiagrams.
- (6) Final results of treatment.

Temperature.—Considering negatively, the temperature was found to have increased in four cases of the sanocrysin group and in three cases of the solganal group. In the remaining cases of the two groups the result was equally good. A difference of one degree or more was taken into consideration in judging the effect on temperature.

Weight.—Of the 33 cases treated with sanocrysin, 25 gained in weight and there was loss in eight patients. In the group treated with solganal, 17 patients gained and three patients lost in weight.

The maximum gain in a patient treated with sanocrysin was 33 pounds and the maximum loss was 21 pounds, while the maximum gain in

a patient treated with solganal was 40 pounds and the maximum loss was 8 pounds only.

Tubercle bacilli.—The effect on the tubercle bacilli at the time of discharge of the patients from the sanatorium was as follows in the two groups :—

	SANOCRY SIN		SOLGANAL	
	Positive	Negative	Positive	Negative
Before treatment.	31	2	17	3
After treatment.	25	8	9	11

It will be clear from the above table that the effect on tubercle bacilli was better marked in the case of solganal than in the case of sanocrysin.

Blood Sedimentation Rate.—In the sanocrysin group the blood sedimentation rate was found to have improved (decreased) in 25 cases and had become worse (increased) in eight cases. In the solganal group, it had improved in all the cases; the Westergren method was employed.

X-ray evidence.—Not much difference was noted in the x-ray evidence of the patients treated with the two preparations. The effect was similar in the two groups.

Results of treatment.—The results at the time of discharge were found to be as follows in the two groups :—

Results	Sanocrysin	Solganal
Arrested	3	3
Much improved	9	8
Improved	11	5
Stationary	4	2
Worse	6	2
TOTAL ..	33	20

It will be evident from the study of the above tables that the therapeutic results obtained from solganal were more satisfactory than those obtained from sanocrysin.

Reactions from sanocrysin and solganal.—We shall now consider the reactions produced by the two preparations. The observation column of the patients' charts was studied from day to day and it was found that while the reactions were of mild nature in the group treated with solganal, they were of sufficient severity in the sanocrysin group. Only four cases of the solganal group were found to have suffered from body-ache and gastro-intestinal disturbances but in the sanocrysin group 26 patients suffered from these and other reactions.

Industrial Tuberculosis Research Worker, Tuberculosis Enquiry, I. R. F. A., All-India Institute of Hygiene and Public Health, Calcutta

THE scope of this paper will be limited to the consideration of silicosis and anthracosis, the pathological conditions of the lung produced by the inhalation of silica and coal-dust, respectively, and their relationship to tuberculosis. A

(Continued from previous column)

Oily preparations of gold.—If the table showing the number of patients treated with sanocrysin and solganal during the years 1931–1936 is studied, it will be noticed that the number treated with the oily preparations has increased every year with the result that by the years 1935 and 1936 the oily preparations had completely replaced the watery solutions. Practical experience has shown that the oily preparations are preferable to watery solutions for the following reasons :—

(1) The oily preparations can be administered without any difficulty. It has been found difficult at times to inject aqueous solutions in patients with poor veins.

(2) Absorption of gold takes place slowly.

(3) Prolonged action is obtained. This is not so in the case of aqueous solutions which are excreted more rapidly.

(4) Reactions and toxic effects are reduced to a minimum.

The fact that oleo-sanocrysin had later to be placed on the market is evidence of the importance of oily preparations of gold. Solganal-B oleosum is preferred by us because, while being less toxic than oleo-sanocrysin, it has given equally satisfactory results. It has also been found that oleo-sanocrysin is more painful at the site of injection than solganal-B oleosum.

Conclusion

Our experience at the King Edward VII Sanatorium at Bhowali has shown that solganal is a safer preparation than sanocrysin in the treatment of pulmonary tuberculosis. While the results obtained from solganal are equally, if not more satisfactory, the complications from it are much less marked and much less dangerous than from sanocrysin. The oily preparations of gold are preferable because prolonged action is obtained from their use and the toxic effects are reduced to a minimum. Solganal-B oleosum has been found in our experience to be less toxic and less painful than oleo-sanocrysin.

large amount of work has been done in other countries on dust inhalation and its harmful effects. Such work becomes more and more important as a country marches progressively towards industrialization. Many of the modern industries, in the process of their workings, produce clouds of dust which float in the air and are inhaled by the workers during the whole time of the working shift. It is, therefore, easy to realize that such intensive dust inhalation may produce pathological conditions in the lung.

Ordinary atmosphere, specially of the cities, also contains dust and everyone inhales dust; but no harm results, as the lungs can get rid of a certain amount of dust. Coarse dusts are generally caught by the ciliated processes of the mucous membrane of the respiratory tract and thrown out by the wave-like movements. Finer dusts enter the deeper parts of the respiratory tract, are engulfed by the alveolar phagocytes, removed to the nearest lymphatic, and are thence eliminated through the lymphatic system. But there is a limit to this capacity for elimination. If by any means the intake exceeds this limit of elimination the result will be an accumulation of dust. This accumulation, if it occurs to any great extent, is likely to cause damage to the system. The nature and amount of damage depend, largely, on the nature and amount of dust inhaled. This is why a consideration of dusts specially encountered in the industrial processes is included here.

Dusts

Prof. Cummins (1935) classifies the dusts into two categories :—

(A) Chemically-active dusts.

(B) Inert dusts.

Of these two types the chemically-active dusts are by far the most important and their presence in any industry must be carefully investigated.

(A) Chemically-active dust

These dusts are soluble in tissue fluid. Of all the dusts in this group, silica-containing ones are the most dangerous. Silica is a tissue poison and produces in the tissue both degenerative and sclerotic reactions. Minute particles of silica dust enter the deeper parts of the respiratory tract during inhalation. These particles are then engulfed by the alveolar phagocytes and carried to the nearest 'lymphatic mass' situated near the terminal bronchioles. Mavrogordato (1922, 1926) thinks that the poisonous action of the silica kills and then mummifies the phagocytes. These later disintegrate in their turn, and the liberated particles are in all probability taken up by other phagocytic cells, so that the process continues. After a time the particles are dissolved and produce the reaction of fibrosis and degeneration. According to King and Dolan (1934), on the other hand, the particles do not linger in the cells for a long time. They soon dissolve and produce the reaction of fibrosis,

that is, silicotic nodule formation. The nodules themselves show almost invariably zones of necrosis at the centre. This central necrosis may be due to high silica concentration at the centre, or to a lack of nutrition here. However this may be, these central necrosed areas eventually become fibrosed. The central necrosis, the surrounding zone of fibrous tissue, and the gradual replacement of the necrotic area by fibrous tissue fibrils, make silicosis almost an identical process, histologically, with the healing stage of tuberculosis.

There are some differences of opinion as to how the silicotic nodules of fibrous tissue are produced. One school believe in the 'mechanical theory'. They think that silica particles act as foreign bodies in the lung tissue without going into solution and just like other foreign-bodies produce a fibrotic reaction. As the particles, carried by the phagocytes, conglomerate in the lymphatic masses, fibrosis occurs round and inside these areas giving them a nodular appearance. But the international silicosis conference at Johannesburg (Irvine *et al.*, 1930) came to the conclusion that the lesions produced in silicosis were due to the solution of silica particles in the tissue fluid and not to any mechanical action. Thus, the solution theory has been accepted as correct to-day.

The reaction to silica particles in the tissue depends on various factors. Chief amongst them are, (i) the chemical composition, (ii) the concentration of silicious material in the atmosphere and in the tissue, and (iii) the size of the dust particles. The following are some of the considerations about each of these factors :—

(i) *The chemical composition.*—It was originally supposed that only free silica was responsible for the production of silicosis, because in experimental animals quartz (free silica) particles produced lesions which were essentially the same as in human silicosis. But Jones (1933) claimed that a fibrous silicate, called *sericite* (a hydrous silicate of aluminum and potassium) was a potent cause of silicosis. During his investigations he found that wherever there was silicosis there was *sericite* as well. Where there was no *sericite* but other silicious materials present, there was no silicosis. Secondly, he found that the bulk of the mineral residue after nitric acid treatment of every silicotic lung specimen consisted of *sericite*. It was for these reasons that he came to the above conclusion. But Watkins, Pichford and Meir, on the other hand, according to Cooke (1935) in a much earlier investigation, concluded 'that the mineral contents of Rand silicotic lungs were identical, physically, chemically and in the numerical ratios of the particles of quartz to that of particles of accessory polarizing mineral, with the finer portions of Rand mine dust. Quartz particles were, of course, by far the most numerous. They add that there was no indication of the physiological selections of particles

except in regard to size'. Robson, Irwin and King (1934) could produce early silicosis in their experimental animals with quartz and dilute gas but they failed to produce such lesions by sericite and gas. Gardner (1934) also found that 'Uncombined silica causes a very rapid necrosis of tissues, which is not produced by silicates and non-silicious dusts'.

Even if we take for granted that the bulk of the residue after nitric acid treatment of silicotic lung specimens consists of sericite, that does not necessarily mean that sericite is the cause of silicosis. It is possible that sericite is retained in the lung as a non-soluble or less soluble residue, whereas some other form of silica being more soluble in the tissue fluid, vanishes from the tissue, and is the real cause of fibrosis. Of course this argument only holds good if we accept 'solution theory' to be correct. Recent work of R. King seems to prove that silica, though otherwise an extremely insoluble mineral, dissolves in tissue fluid. The International Silicosis Conference in 1930 accepted the 'solution theory'. The problem then is: Is free silica more or less soluble than silicates? Jones suggested, according to Cummins (1935) in his original publication (Jones, 1933), 'that sericite mineral is less stable and its particles, because of their physical form, expose far greater surface to volume for any chemical action than do the more compact grains of quartz'. Therefore sericite is more soluble. But this has not yet been confirmed, nor has it been universally accepted. Efforts have been made to find out the solubility of quartz and sericite *in vitro*. Titus (1937) studied the solubility in distilled water and serum, and could not find any difference in their solubility *in vitro*. However this may be, the fact seems to be that the solubility of the particular dust in the tissue fluid, which depends on its chemical composition, may be one of the important factors in the production of silicosis.

The record of work done on this aspect seems to show that free silica is mainly responsible for the production of silicosis. The effect of silicates, except asbestos (asbestosis is a different condition), is rather doubtful. If they have any it seems to be less important.

Middleton (1936) gives the following figures regarding the death rate from silicosis in silica and silicate industries in England and Wales:—

Processes involving exposure to silica dust—

(1) Sandblasting ..	6.4 per 1,000 living
(2) Refractories industry ..	3.0 " 1,000 "
(3) Sandstone industry ..	3.0 " 1,000 "
(4) Gold and tin mining ..	11.0 " 1,000 "
(5) In 'flint and pebble crushing', 'manufacture of abrasive soaps', 'polishing and grinding', 'granite and slate industries', 'coal mining' and 'pottery industries'.	Actual data not given but is stated to be 'high'.

Processes involving exposure to dust of silicates:

- (1) Asbestos (causes generalized fibrosis)—High death rate.
- (2) Sillimanite, kaolin, talc, French chalk, mica (causes mild fibrosis)—Not highly dangerous.

(ii) *Concentration*.—There is experimental evidence to show that the nature of damage of tissue by silica depends on the concentration of the mineral in solution. Gye and Purdy (1922 and 1924) showed that silica in colloidal form was a cell poison. When injected intravenously in a concentrated form, it caused death by degeneration and necrosis; but, in a dilute form, it caused proliferation of connective tissues. The 'solution theory' of silicosis, first suggested by Collis, was supported by this experiment. Tissue fluid dissolves silica very slowly and the liberation of colloidal silica in minute quantities probably causes the proliferative reaction. The result is fibrosis of the lungs.

It is easy to understand that the higher the concentration of silica dusts in the working atmosphere, the greater would be the chance of a high concentration of the mineral in the lung tissue. According to Cummings (1934) if the concentration of silica dust does not exceed 5,000,000 particles per cubic foot of air, as determined by a light field counting method, a normal man may work in this atmosphere unimpaired in health. This now raises important considerations, and, if confirmed, may be of use in establishing a limit for safe working. It is probable, however, that the duration of exposure to dust plays as important a rôle as the concentration. It is common experience amongst the workers of the mines that they develop silicosis after working in silica-laden atmosphere for a very long period. The cumulative effect of silica particles in the lung may produce silicosis even if the threshold mentioned by Cummings is not exceeded. It is also very likely that the workers, though ordinarily exposed to dust concentration below the threshold, are subjected to intensive dust-inhalation at certain periods of the working shift when the concentration of dust particles in the air exceeds the threshold. This intermittent intensive exposure may be one of the causes which lays the foundation of silicosis. The lesions develop slowly and it takes years, generally, for them to come to the stage when they produce clinical symptoms.

As regards the rate of development of the lesions, Cummings found that the rate increased slowly with the elevation of dust concentration. But from a certain level the acceleration becomes very marked. Concentration of 100,000,000 or more quartz particles per cubic foot of air was regarded as extremely hazardous and constitutes what Cummings called the "secondary threshold". In concentration above this secondary threshold silicosis might be expected to develop rapidly. In the process of sandblasting this higher threshold is probably reached or

exceeded. It is why the blasters fall a prey to silicosis very rapidly. Granite workers are attacked with the disease much sooner when they are working underground where ventilation is not good and consequently, because of less dilution, the concentration of dust is high. These workers, when they are working above-ground, do not suffer greatly; but they do so, when they use pneumatic drills (Sutherland, 1931) which cause excessive concentration of dust. Tatham pointed out that, since 1881, the fatality due to non-tuberculous diseases of the lung has increased greatly in all the coal-fields of England. Cummins (1932), quoting Tatham, asks why the fatality should increase when the general amenities of coal-mining were improving and when the mortality from pulmonary tuberculosis was falling steadily in all sections of the population? He attributes this increase to the introduction of mechanical drills in the mining industry which produce intensive dust concentration. About fifty years ago, before the advent of mechanical drills (to bore through layers of stone between the seams of coal) in coal mining industry, a miner bored a heading at the rate of a few feet a day with the hammer and chisel. But nowadays he bores at the rate of four feet in half an hour with a mechanical drill. Williams (1933) points out that in such cases 'there is an increase of rock dust produced corresponding to the increase in extent of rock drilled in the man's working shift'. The risk, therefore, is far greater when the workers use these modern devices—steam, electric, or compressed-air drills, as the case may be. These findings seem to show that the lungs can deal with the dust to a certain extent. If the output or elimination balances the intake no harm results. But when the entry is greater than elimination, accumulation begins and gradually the pathological process is established. During the writer's (1937) investigation amongst the South Wales coal-miners he detected a number of cases of silicosis in young workers. Such young workers never used to get the disease before the advent of these modern contrivances.

(iii) *Size*.—The size of the particles of the dust-cloud emitted during the working process has a very definite relationship to the production of disease. The smaller the size of the dust particles the longer will they float in the air. Thus, they afford a better opportunity to be inhaled by the workers, and, as they maintain the concentration of silica per cubic foot of air higher, it is more likely to produce silicotic reaction.

It is possible that the size of the particle has definite relation to its penetrative power in the deeper parts of the respiratory tract. The bigger the particle, the more likely is it to be caught in the external respiratory passage and thrown out without producing any harmful effect. The microscopic examination of silicotic lung tissue after acid digestion shows that about 70 per cent of the silica particles are of a diameter less than

one micron; and the remaining thirty per cent varied between one and 6.5 micra. This finding introduced the idea that particles up to 5 or 10 micra are 'respirable', and those above ten micra are not 'respirable'. Cooke believes that this division of dust into respirable and not respirable is not proper. He says that in the trypsinized deposits, which also contain those minerals that are soluble in acid, one often sees particles measuring from 20 to 100 micra in length in the lung of coal miners. Halliburton and McDowall (1933) stated that the average size of the alveoli was 300 to 500 micra. It is therefore likely that large mineral particles may be inspired into the lung where they can reach up to the alveoli. Whether such large particles can do chemical or mechanical damage is, of course, doubtful. Gardner and Cummings (1933) found in their animal experiments that the size of the particles in tissue has a definite relationship to the nature of the lesion produced. 'Particles less than one micron in diameter act quite like colloidal silica and cause acute inflammation and even death from necrosis of the liver within a few weeks. Particles of from 1 to 5 micra in size produce progressive fibrosis in the liver, with the formation of nodular lesions similar to those in the lungs caused by inhalation of silica dust. Particles of from 10 to 12 micra in diameter stimulate the formation of small foreign-body tubercles which do not change materially during a period of two years'. It may be deduced from these experimental findings that large particles, even if they enter the deeper parts of the lung, are not responsible for the production of silicosis.

This difference of reaction may be explained by the 'solution theory' of silicosis. The size becomes an important factor in the solubility of silica. The smaller particles expose a greater total area of the dust to the action of plasma. The result would be rapid solution leading to greater concentration of the mineral in the tissue in a given time. This difference of concentration produces different reactions. Mellor (1913) supplied definite data regarding their solubility *in vitro*. He made emulsion of powdered rock crystals and flint with 15 per cent solution of potassium hydroxide and worked out the following data:—

Average diameter of grain	..	165 micra	32 micra
Rock crystal dissolved, per cent		0.96	6.40 "
Flint, dissolved, per cent	..	2.52	12.10

Thus, it was evident that the solubility of the mineral increased by about 6 times as the size decreased by about 5 times. That this might occur in the tissue fluid in the lungs in a modified form was deemed possible.

From what has been said before it seems that the smaller the dust particle the greater is its capacity to produce disease. It is also likely that very large particles do not cause any harmful effect. Cummings (1934) is of the opinion

that the 'effective size range' of particles causing disease is 5 micra and under. Franks (1934) thinks that the most dangerous size is from $\frac{1}{4}$ to 6 micra in diameter.

Silicosis and tuberculosis

The presence of silica dust in certain industries is not only dangerous for the fibrosis of the lungs it induces but also it makes the tissue very susceptible to tuberculosis. Gardner (1929) was able to produce progressive disease in silicotic animals by an avirulent strain of tubercle bacillus (R_1) which in the normal animal did not produce progressive disease. That the association with silica makes the bacillus more virulent could not be proved by him. Kettle (1924) has shown that a necrotic area in a tissue produced by silica predisposes this focus to the localization of tuberculosis more than any other foci of necrosis initiated by other irritants. He (1930) also showed that, proportionately, more tubercle bacilli could be detected in the lesions produced by silica solution and tubercle bacilli than those due to tubercle bacilli alone. He thinks that this adjuvant action of silica is entirely due to the nature of the dust. Cummins and Weatherall (1933) have shown that this 'tuberculophile' action of silica is strictly local and of short duration. He also thinks that in silicosis an accumulation of tubercle bacilli around areas of lymphatic obstruction may occur. Irvine *et al.* (1930) stated that 75 per cent of silicotics of South Africa died of tuberculosis. Sweany and others (1936) in their pathological study detected tuberculosis in all but a minority of silicotics. There are many other instances in the literature where a very high death rate from tuberculosis amongst the silicotics has been recorded. Why and how this 'tuberculophile' action occurs is not yet brought to light. The probability is that silica changes the reaction of the tissues in some way which makes them more liable to infection. Cummins suggested that the nature of this change might be an inhibition of the complement by colloidal silica. The proof is still to be sought.

Whatever may be the reason, the facts prove beyond doubt, that tuberculosis is very much more frequent in silicotics than in other sections of the population. In fact, there are authorities who define silicosis as a malady characterized by fibrosis of the lung at the beginning and tuberculosis in its later stages. Such definition, of course, is open to question but shows clearly the relation of silicosis to tuberculosis.

In view of these facts various efforts have been made to minimize the risk of silicosis by introducing masks, water sprays, etc., but it has not been too successful on account of the handicaps that accompany these measures. In a very recent investigation by Denny, Robson and Irvin (1937 and 1939), it was found that animals could be protected from silicosis by adding a very small percentage of aluminium dust to the silica dust. This important finding

opens out a large field of investigation. Whether aluminium dust could be mixed with the silica dust in the working atmosphere and whether such mixture would prevent human silicosis are still the unsolved practical problems of the day.

Silicosis in India.—It has been repeatedly said that in India the problem of silicosis is not acute. Whether because of the crust over the mineral or of some other different chemical nature of the mineral, it has been said that the workers of the Kolar Gold Fields do not get silicosis. But a very thorough investigation is needed before any pronouncement on such a vitally important problem is made. There is no doubt that the workers of other silica industries in India, numbering many thousands, are exposed to the grave risk of silicosis and subsequent tuberculosis. No organized effort has yet been made to survey some of these industries to find out the amount of tuberculosis and silicosis amongst the workers, and how best these could be prevented or minimized in relation to the conditions in which these workers are employed. Civilization and industrialization have brought with them many of the amenities of life, but they have brought associated evils too, and science, supported by the state, must attempt to cure some of these evils where possible.

Besides this grave risk of tuberculosis, silicosis itself causes various symptoms the chief amongst them being dyspnoea. This is an extremely distressing symptom and disables the workers in a very short time. When well developed they can hardly walk without halting every few steps. They gasp for breath at the slightest exertion, they are unable to work and life becomes a real misery. In the writer's investigation (1937) amongst the silicotic coal-miners in South Wales, it was found that workers were disabled by this symptom within about two years from the onset of the symptom.

It was generally thought that dyspnoea was mainly due to the gradual increase of fibrosis and consequent diminution of aerating area of the lungs. It was also known that once the lung was strewn with silica dust, fibrosis progressed even when the worker left the work and the atmosphere, so that no good could be achieved by removing the worker from his work at the advent of dyspnoea because fibrosis would proceed all the same and dyspnoea increase whether he left or stayed at his work. But the writer (1937), from radiological evidence, suggested that this rapid increase of dyspnoea might be due to the rapid production of emphysema, while the worker was doing hard underground work which caused forced breathing. Cummins (1938) also called attention to emphysema as a factor in the causation of dyspnoea of pneumoconiotic coal-miners by his histological study on such lungs. If the contention of the writer is right, then much suffering of the silicotic miners could be minimized by taking them off from hard underground work and putting

them on to some kind of light work on the surface. This may keep the degree of dyspnoea at a much lower level all through his life and may enable the miner to lead a useful life for a much longer period.

That silicotic tissue is susceptible to tuberculosis has been stated. There is another side of the question, that is, whether or not an arrested or quiescent tuberculous lesion may flare up in association with silicosis? It seems to do so. The ground is prepared for re-activation through increased susceptibility. Besides, the stress and strain on the lungs that dyspnoea causes may easily be a potent factor in starting up an arrested lesion. That is why it is important that the workers for entry into any silica industry should first be thoroughly examined regarding the presence of tuberculous lesions—active or arrested. If any lesion is detected, it is better that he is not admitted into the industry.

Another problem which often arises in connection with compensation claims is whether the worker developed tuberculosis on a date prior to or after his entry into industrial life. The employers may protect themselves in some cases by an initial examination before the recruitment of the workers. A pre-employment medical examination is, therefore, helpful for both the employee and employer.

(B) *Inert dusts*

Inert dusts are those which are insoluble in body fluid. Coal-dust belongs to this group and might cause fibrosis of the lungs when inhaled in a large quantity. There are, of course, many authorities, as for example Kettle (1933-34), who believe that silicon derivatives are the only dusts to be reckoned with in the production of pneumoconiosis. Kettle writes as follows: 'So far as I know, no substance other than silicon derivatives causes more than a very moderate degree of fibrosis of the lungs, certainly not enough to interfere with its functions'. Willis (1921 and 1922) could detect some fibrosis of the lungs in his animals which were exposed to coal-dust for two years, but failed to detect any fibrosis in one year. Cummins (1935), on the other hand, believes that if the dusts accumulate in any marked extent they exert mechanical action characteristic of foreign bodies and produce a certain amount of diffuse fibrosis around the dust deposits. Gardner (1933) also thinks that coal and hematite tend to produce sub-pleural and peri-lymphatic pigmentation with the formation of considerable cellular connective tissue in these locations. The writer (1937) in his series of cases detected a large accumulation of dust and considerable fibrosis in screeners of the mining industry who work on the surface and inhale only coal-dust, in contrast to the underground workers who inhale stone-dust also.

It is, therefore, probably true that inert dusts, when inhaled in a large quantity, may accumulate and produce diffuse fibrosis by the 'foreign-body' reaction. But, so far as is known, this fibrosis does not impair the functions of the lung to any great extent and cause much disability. This is why the presence of such dusts in the industry is not so dangerous as the presence of chemically-active dusts.

Mixture of chemically active and inert dusts

Coal-mining industry does not consist in dealing with coal only. Between the seams of coal there are layers of stone, rich in silica. In order to get at the coal, these layers of stone must be 'hored' through or demolished by 'shot firing'. Those men who work on the stone are classed as 'hard-ground' workers. They are borers, shot-firemen and repairers. These men are subjected to intensive stone-dust inhalation and may suffer from silico-anthracosis. Other underground workers in a coal mine, e.g., hewers, are also exposed, though not to so intensive inhalation of stone-dust. In fact, an analysis of dust in the South Wales steam-coal-mines by the team workers of the Welsh National Memorial Association (Brownlee *et al.*, 1931) showed the following results: (a) from floors, 60 to 70 per cent stone-dust and 30 to 35 per cent coal-dust, (b) from roof and sides, 75 to 85 per cent stone-dust and 15 to 25 per cent coal-dust. Such findings show that all underground workers in a coal-mine inhale large amounts of silica-containing dust during their working hours. Some writers, as for example, Haldane [Kettle (1933-34) and Carleton (1924)], believe that the coal-dust in human tissue acts as a stimulant for the brisk action of the phagocytes. For this reason it is responsible for the rapid elimination of much of the silica-containing dust and thereby acts as an ameliorating agent in the production of silicosis. Kettle (1930) doubts this. His experiments confirmed no such 'characteristic cleansing property' of silica by coal-dust.

Coal-dust, on the other hand, mixed with silica dust, might produce 'accumulative effect' instead of 'cleansing effect' as has been suggested. Silica-dust will produce fibrosis in and around the lymphatic system, thus obstructing the portal of exit of the coal-dust. Thus a liability to retention of this dust will occur which in a normal lung would go out unhindered. Cummins and Sladden (1930) and Cooke (1932) are of opinion that the retention of coal-dust in quantities sufficient to cause anthracosis seems to occur only in the presence of silica-dust. The amount of silicotic fibrosis at which lymph stasis may occur to a sufficient extent to lead to retention of another type of dust has not yet been determined, but Cummins (1935) thinks that it probably falls far short of what might be expected to produce recognizable silicosis where silicious dust alone is in question. In cases investigated by him 'there had occurred a vast and dangerous accumulation of coal-dust in lungs

of which the total silica in ash, as determined by chemical analysis, was only about twelve to fourteen times the normal, whereas in advanced cases of silicosis the percentage may be from thirty to fifty times the normal, taking the normal as about 1 per cent'. With this background of silicosis the accumulation of coal-dust may be very great. An advanced anthracotic lung of this type is full of coal-dust and at places looks like solid coal. That much of the miner's dyspnoea is due to this seems to me to be beyond doubt. The anthracosis of a coal-miner is then a 'dual condition'. Coal-dust, though not harmful in itself, through this blocking of the lymphatic system by silicotic fibrosis, accumulates and produces harmful mechanical effects.

Silico-anthracosis and tuberculosis

The diagnosis of tuberculosis in pure silicotics is much easier than in silico-anthracosis. In silicosis, the x-ray picture shows discrete nodulation throughout both the lung fields and at a later stage these shadows conglomerate to form dense opacities in some areas. Tuberculous infiltration in such a lung shows a localized area with all its characteristics which may be differentiated from the nodular shadows of silicosis. But in anthraco-silicosis the nodular character of the shadows is lost and the mottlings tend to be hazy or fuzzy in appearance. Pancoast *et al.* (1934) in such cases suspect the presence of tuberculosis if the mottlings are peripherally situated and if the trachea is deviated to one side. In addition to these the present writer thinks that one should note the fluffy look of the shadows, lack of demarcation, signs of breaking down of tissue and apical localization, to diagnose the presence of concomitant infection. If the periphery of the shadow is much less dense than the centre and spreads irregularly, one should suspect the lesion of tuberculosis along with pneumoconiotic fibrosis. Belt (Pancoast, *et al.*, 1934a) noticed in many cases fibrosed nodules surrounded by tuberculous tissue. Such lesions produce the above picture.

Besides these radiological difficulties the clinical diagnosis of tuberculosis in silico-anthracosis presents difficulties too. In pure silicosis the toxæmic symptoms of tuberculosis reveal themselves, whereas in silico-anthracosis these symptoms are generally masked. Cummins and Weatherall (1931) showed that coal-dust is capable of adsorbing the active principle of tuberculin in very dilute solution. It is, therefore, likely that some such action of adsorption of tuberculin by coal-dust occurs in the lung tissue and amelioration of the toxic symptoms results. This makes the 'miners phthisis' benign and eludes the diagnosis of tuberculosis in most cases. These are diagnosed generally as cases of bronchitis. In an unpublished work, the writer, to find out the frequency of tuberculosis in silicotic coal-miners,

made a histological study of such lungs and detected the presence of tubercle bacilli in 42.08 per cent of lung specimens. He (1937) made clinical and laboratory studies of the silicotic coal-miners and found 35 per cent (12 definite and 23 probables) had tuberculosis, many of whom had no symptom of the disease. In view of these findings the writer came to the conclusion that there was a high incidence of tuberculosis amongst the silicotic coal-miners and that coal-dust modified the toxicity of tuberculosis, leading to failure to recognize the disease, and to the mistaken diagnosis of bronchitis. These undiagnosed men spit out tubercle bacilli and infect their families and fellow workers. Thus, bronchitis amongst these men should be viewed with suspicion and thoroughly investigated before such a diagnosis should be accepted.

Predisposition

Though the nature of the dust is responsible for the production of pneumoconiosis and tuberculosis, it will be giving a wrong idea if we accept this as the only cause. Hundreds of workers work under the same conditions and are exposed to the same kind of dusts. Not all of them suffer from the disease. This raises the question of soil or the condition of the body. This predisposition to pneumoconiosis lies, very likely, in the deficiency of the eliminative function of the lungs. In this case, a congenital origin or familial predisposition seems likely; but an enquiry in this direction by the writer did not justify the conclusion that such family predisposition existed.

In this connection the dust-filtering efficiency of the human nose has also been blamed by Lehman (1935). He claimed that this efficiency varied a great deal between healthy persons and the silicotic miners. In healthy persons of various ages, 65 per cent had retention efficiency over 40 and only 10 per cent below 30, whereas in the silicotics only 20 per cent were over 40 and 62 per cent below 30. Thus, he suggested that people with bad filtering efficiency were liable to pneumoconiosis. Mouth breathers evidently do not get the advantage of this filtering action of the nose and may be more prone to pneumoconiosis.

The main considerations should certainly be directed to the eliminative system of the lungs. Any damage to this system is likely to cause retention of dust. The relationship of the damage of the respiratory mucous membrane to the production of silicosis has been shown in experimental animals by Robson, Irwin and King (1934). They could produce earlier and more acute lesions of silicosis in those animals whose respiratory mucous membrane had previously been damaged by the inhalation of dilute irritating gases (NO_2 and SO_2). Their above experiments tend to show that the noxious gases produced after shot-firing in coal-mining industry may be a very important

factor in the production of early silicosis. In fact, these miners have been found to suffer from silicosis in a very large percentage.

There are differences of opinion regarding ordinary bronchitis as a predisposing cause. Haldane (discussion of Fisher's paper) was of opinion that this was one of the major factors in the production of pneumoconiosis in South Wales coal-miners, but Kettle does not believe that bronchitis causes deficient elimination. If it does anything, it enhances the expulsion of dust with the coughing out of the mucus from the respiratory passages.

The lymphatic drainage system, if blocked by any disease, will cause an accumulation of dust. Tuberculosis of this system may be one of the contributory factors. The part it plays in the production of pneumoconiosis has been described by Gardner (1925) in the following words: 'In case the nodes are normal, many years will be needed to obstruct them; while nodes already heavily involved with healed or healing tuberculosis would more readily react to smaller amounts of dust, and an obstructive fibrosis would occur after a much shorter time. Such an explanation could account for the great irregularity in the time required for the development of demonstrable silicosis in industry'. Any other parenchymal disease of the lung which causes localized damage to the lymphatic system should also be counted as a predisposing factor. Besides tuberculosis, atelectasis, chronic unresolved pneumonia, localized fibrosis due to any disease, and localized pressure due to any growth, all fall into this group.

From the above considerations it will be evident that pre-existing diseases of the lung may play a very important part in paving the way for the production of pneumoconiosis. In view of this a thorough medical examination of the worker before he is employed in a 'dusty industry' is of the very great importance for the prevention of pneumoconiosis, specially in cases of industries producing dangerous dusts in their processes.

TUBERCULOSIS OF LYMPHATIC GLANDS IN THE NECK

By M. M. CRUICKSHANK,

LIEUTENANT-COLONEL, I.M.S.

Professor of Surgery, Medical College, Madras

TUBERCULOSIS of lymphatic glands is characteristically a disease of childhood, occurring usually in the first year of life, running an acute course in the beginning, but, with every succeeding year of life, tending to chronicity, because of the increasing resistance established in the child's body. Cervical tuberculosis is more prevalent than the glandular disease elsewhere and

is frequently the first manifestation of the disease.

The infection is carried by two paths, by the lymph and by the blood stream. The lymph spread is by far the more common and occurs in a large majority of cases, the primary focus being in the tonsil, in nasopharyngeal adenoids, or in carious teeth.

A clinical distinction of the two groups is usually possible, because with a blood infection multiple scattered glands are more likely to be attacked, whereas with a lymph infection the disease remains for a long time confined to one or two adjacent glands. Therefore, operation is contra-indicated in cases due to blood spread.

The anatomy of a lymph gland presents some very interesting features. Between the lymphoid tissue of the interior of the gland and the fibrous capsule surrounding it, lies a narrow channel, bridged across by strands of connective tissue. This channel is called the 'gland corridor' and the interlacing septa of connective tissue are of the nature of filters which arrest the organisms in their course through the gland.

At the hilum, blood vessels enter and leave the gland, and efferent lymphatics emerge, while the afferent lymphatics pierce the capsule to enter the gland at various sites around its periphery. The lymph stream enters the surface of the gland by afferent vessels, circulates through the corridor, permeates the lymphoid tissue, and emerges at the hilum through efferent vessels. Therefore, in a lymph-borne infection, caseation commences at the periphery of the gland since the lymph stream reaches the gland at that point: whereas in a blood-borne infection it begins at the centre, because the main blood vessel passes to the centre of the gland before it breaks up.

If the infection is a lymphatic one then the chief portals of entry are, as I have already said, the tonsils, the lymphoid tissue of the nasopharynx (adenoids), and the teeth. The bacilli are carried into the lymphatics by phagocytic cells and are deposited in the lymphoid tissue of the first lymph gland arrived at. The toxin produced by the bacilli precedes the bacilli and sets up an intense lymphocytosis in other glands through which the lymph passes, narrowing lymph sinuses, filling them with lymphocytes, and thus rendering the glands less pervious to the passage of tubercle bacilli.

Secondary tuberculous adenitis of the cervical glands may be associated with tuberculous ulceration of the tongue, lips, pharynx, larynx, nose, etc., or with tuberculous middle-ear disease, rarely secondary to lupus of the face. In these cases the glandular disease is not usually extensive and is of less importance than the primary affection.

Of the various groups of glands affected by the disease, those draining the tonsils, the adenoid tissue of the pharynx, and the teeth, naturally show special liability to infection, the

highest individual incidence. The disease has a high incidence in the jugulo-digastric

The lower deep cervical glands are often enlarged during the course of tuberculosis of the lung, or as a result of infection of the tracheo-bronchial glands. This is often affected as a sequel to abdominal tuberculosis, the infection being conveyed by the lymph duct. Infection of the lower cervical glands is frequently followed by the appearance of enlarged glands in the axilla, a retrograde infection along lymph vessels.

If, however, the infection is blood borne, the original site of the disease may be difficult to find.

Pathological changes

Infection having occurred, pathological changes are set up in the gland, and these changes are of two types:—

1. In the *caseating form* the changes are typical of tuberculosis in other parts. Tuberculous follicles are seen with a central area of endothelioid cells containing giant cells surrounded by a zone of lymphocytes. Caseation occurs in the central area and enlargement of the caseous area and confluence of adjacent tubercles may proceed until the whole gland is replaced by white cheesy material.

At any stage, the disease may be overcome and follicles replaced by fibrous tissue and ultimately calcification may occur. Such calcified tuberculous glands are very common, especially in the mediastinum or in the mesentery of the small gut, though they are less often found in the neck. If the disease progresses, peri-glandular connective tissues are involved and adjacent glands become adherent to one another. Cold abscesses may develop and may infiltrate fascial planes and muscles. Eventually abscesses point at the skin surface and burst, leaving tortuous sinuses which remain as long as the glandular infection persists.

2. In the *proliferative form* the pathological process is of a different type. Giant cell systems are scanty or absent and there is little or no caseation. The glands are swollen and elastic, on section fleshy and greyish pink. Microscopically, the characteristic feature is a diffuse proliferation of endothelial cells with a variable degree of fibrosis. Obviously here the differential diagnosis is from lymphadenoma and the distinction is often difficult.

Just as there are two methods of dissemination, two types of pathological change, so, two distinct clinical types may be recognized.

In the first, the adenitis is a manifestation of a widespread tuberculosis. The patient is pale, thin and anæmic with active disease in the mediastinal lymph glands and in the lungs. The affected cervical glands are multiple and situated in both anterior and posterior triangles of the neck on both sides. The glands, not greatly enlarged, are of soft consistency and rarely caseous.

factor in the fact, the second type, and this is the type more from in surgical practice, the child is often poorly looking and shows no other evidence of tuberculous disease. The condition is purely a local infection. Generally one gland is grossly diseased, whilst a few adjacent glands are involved to a lesser degree. The principal gland affected is usually the jugulo-digastric, or tonsillar, gland, in the angle between the common facial and internal jugular veins. Less often a submaxillary gland or one in the posterior triangle or lower part of the neck is the main site of the disease.

In this type the gland principally involved may progress to caseation and to the formation of a cold abscess and the skin over the abscess may break down and a tuberculous sinus result.

Clinical features of tuberculous glands

The features of tuberculous glands are their chronicity, the peri-adenitis fixing the glands more or less to surrounding tissues, the infection of many glands and their tendency to soften. But variations are met with, as we can surmise from the pathology; the disease may be almost acute, there may be no obvious periadenitis, the disease may be limited to one gland, softening may not occur, and the glands may calcify.

If the disease progresses, further peri-adenitis leads to matting of the glands into one nodular mass, caseation may occur, cold abscesses may form, and a mixed infection may be added, with true suppuration. Sinuses lined by granulation tissue form, leading from gland to gland, and these refuse to heal until all granulation tissue has been destroyed. A cut section of such a gland shows translucent grey patches in the earlier stages; later, these become opaque, yellowish and granular owing to the occurrence of necrosis and caseation. With the occurrence of suppuration a creamy homogeneous yellow fluid exudes from the cut surface.

Symptoms and course

An indolent, painless, slow enlargement of glands with no deterioration in health is a characteristic feature. Later on, when the glands caseate, there is some degree of malaise with some little diminution in energy and strength, and the evening temperature tends to rise.

With the onset of softening and abscess formation there is pain, and tenderness, stiffness of the neck, the skin becomes red and discoloured and constitutional disturbances become still more marked. Progress in some cases may be rapid, group after group of glands being involved, until finally the patient dies of generalized tuberculosis or of tuberculous meningitis.

The differential diagnosis

It is well to remember that the superficial cervical glands are not liable to tuberculous infection and therefore when they become enlarged, there is very little tendency to a peri-

adenitis, so that they are readily felt slipping about under the platysma.

A *simple acute or subacute adenitis* may present difficulties because acute cases of tuberculous infection do occur. The problem of diagnosis is a difficult one in early cases but in time the simple cases subside while the tuberculous ones persist, and if abscess formation should occur, then aspiration and bacteriological examination of the pus will decide the diagnosis.

Similarly, the *simple chronic adenitis* which accompanies enlarged tonsils, carious teeth, and skin conditions, clears up when the source of the infection has been dealt with.

Lymphadenoma is said to resemble tuberculous disease of glands but the indirect distribution, the smaller, firmer discrete glands, which never soften and break down, serve to distinguish Hodgkin's disease. Add to this a blood picture of eosinophilia, an enlarged spleen and a Pel-Ebstein type of temperature chart and the diagnosis does not long remain in doubt*.

The glandular enlargements of *lymphatic leukaemia* are excluded by an examination of the blood, while the lymphosarcomas are recognized by their painful and more rapid growth.

In *secondary syphilis* the glands are symmetrically disposed in many regions, are multiple, firm, and freely movable, and not tender. It is well to remember, however, that in chancre of the lip or mouth the glands may be matted together in painless masses.

Secondary malignant glands are recognized by their progressive increase in size, by their fixity on account of infiltration of surrounding tissues, by their hardness and the pain elicited on palpation.

When suppuration occurs, then one has to think of a *simple acute abscess*, or of a *suppurating branchial cyst*.

An acute abscess is under a certain amount of tension, the reddened skin over the abscess is œdematous, and extends beyond the limits of the fluctuating area. In a *cold abscess* on the other hand the tension is low, there is no œdema, and the area of fluctuation extends to the limits of the red area of the skin.

A suppurating branchial cyst, like a tuberculous abscess, lies under the deep fascia but a branchial cyst is single and unilateral while it would be rare indeed to find a single unilateral tuberculous abscess.

The prognosis

This is affected by the answer to the question 'Was the infection lymph borne or was it blood borne?'

* We do not agree that the differential diagnosis on clinical grounds is as easy as this. Neither eosinophilia nor the Pel-Ebstein temperature chart are constant, and splenic enlargement is too common a finding to be of much diagnostic value in this country. The Gordon test in the early stages and the histological examination of the glands, later, are the only certain diagnostic tests for Hodgkin's disease.—EDITOR, I. M. G.

In the former case one is dealing with a local manifestation of a local disease which for some time at least remains local. In the latter, a tuberculous septicaemia is pre-supposed, and the future outlook is correspondingly imperilled.

Therefore, the association of cervical disease with a tuberculous lesion in another part of the body, the irregular distribution of the tuberculous disease in the neck, the central manifestation of the disease in the gland, all evidence suggestive of a blood infection in contrast to a lymphatic one, tend to increase the gravity of the prognosis.

The prognosis deteriorates still further when the posterior chain of glands becomes infected, because of the danger of the formation of a retro-pharyngeal abscess and again when the supra-clavicular glands are involved when the spread of infection to the lungs or mediastinum is to be feared. In very young children the prognosis is bad, because of the absence of any acquired immunity.

Treatment

This is a most controversial subject. Opinions are diverse and must remain so until a specific remedy for tuberculosis is discovered. One might classify treatment as, (a) prophylactic, (b) general, and (c) local.

(a) Prophylactic treatment naturally comes first and is all important. Prophylaxis means protecting our children and in safeguarding their food supply. This means dealing in the first instance with milk supplies and a campaign for a pure-milk supply and for a sufficient diet would be of more value by far than any plans, however elaborate, for devising bigger and better operations for the removal of tuberculous glands or for the provision of larger sanatoria for the treatment of tuberculous patients. That is, a campaign for compulsory and controlled pasteurization of milk in quantities sufficient to meet the minimal requirements of our growing infants*.

To safeguard the child means that we must find, isolate, educate and treat all adult cases.

Some years ago when I visited the large leper settlement then on Robin Island in Table Bay, the doctor in charge said to me 'here you see us in South Africa dealing in this stringent manner with a disease, leprosy, the lethal effects of which pale into insignificance compared with the killing effects of tuberculosis, a disease about which we do next to nothing'. That, fortunately, cannot be said to-day of us in India, but the statement holds more than a grain of truth.

General treatment plays an important rôle before the disease attacks the exposed child, but

is of maximum importance when the disease has claimed its victim.

The child must be put under the best possible conditions with regard to hygienic surroundings, be given a liberal diet, a moderate amount of healthy exercise, and by medical attention the natural resistance of its body must be increased to secure if possible a natural arrest of the disease.

We hear much about the beneficial effects of sunlight, little about the evil effects of bad housing and poor general economic conditions. Listen, however, to what Sauerbruch says:—

'The remarkable fact is that swollen tuberculous glands in children who live in high mountains will not heal up in spite of the sun and direct radiation, but rapidly improve at sea level or when treated by brine baths in the plains. How can we explain such a paradox?

The intensity and character of the solar radiation varies with the angle of incidence of the sun's rays, the density of the atmosphere through which they penetrate, the purity of the atmosphere, the presence in the air of moisture, dust or smoke, the amount of sky-shine and of reflected light, the intervention of passing clouds. Moreover, latitude, locality, altitude, climate, temperature, direction and force of the wind, proximity of sea, mountains, rivers or lakes, forests, fields, and even the nature of the soil, all are factors not to be neglected.

Thus, we see that sun treatment, wherever undertaken, must be administered under continually changing conditions, even when applied in one particular district. The one unchanging factor is that, of constantly changing conditions, light is a tonic to both mind and body'.

One remarkable piece of evidence of the beneficial effect of light is seen in its influence on the healing of sinuses and this when light is applied to the body as a whole and not to the sinus itself. The effects of sunlight can be obtained by a carbon arc lamp of 25 amperes. The result is a definite improvement in the hæmoglobin content of the blood, in weight, in calcification of bones, and in well-being and energy.

Great stress is laid on measuring the doses of sunlight in treatment, beginning with half minute exposures to each side of the body at a sitting and in increasing the exposures to a maximum of 15 minutes to each side of the body.

Rollier of Leysin, to whose genius we owe the inception of heliotherapy, began by exposing the feet for 5 minutes twice daily and continued exposing more and more of the body till the whole was exposed, till finally the children lived in such sunlight as was obtainable in northern latitudes.

Exposures, however, may be overdone with resulting malaise, a feeling of lack of well-being, loss of appetite, some pyrexia, and perhaps an increase in local symptoms.

Tuberculin and pure protein derivatives have their advocates, abscesses being merely aspirated. Large masses of tuberculous glands will

* Whilst any measures that would ensure a purer milk supply *without adding to the cost of the milk* would be welcome on general sanitary grounds, we must remember that bovine tuberculosis is extremely rare amongst cattle in India. Pasteurization of milk cannot in these circumstances be considered as an important method of reducing tuberculosis in India.—
Editor, I. M. G.

disappear after milk treatment and Halliday Sutherland reports a case of a child who had suffered from discharging tuberculous sinuses for 2 years, whose condition cleared up in 6 weeks with tuberculin treatment.

Tuberculin is of value after operation because, though tuberculous glands have been removed, others are likely to have been left behind, and, though tuberculosis of lymphatic vessels has not been demonstrated, yet their fluid contents might well contain living tubercle bacilli.

Again, on the other hand, to the prolonged use of tuberculin is attributed peri-glandular adhesions, which will, if operation is decided upon, increase the difficulties of excision.

Local treatment.—The many and diverse views with regard to local treatment might be summed up under four headings:—

1. Where it is considered that all cases should be treated by medical and by conservative means, the only surgical and local treatment being aspiration of breaking down glands.

2. Where it is considered that all diseased glands should be excised.

3. Where it is considered that surgical treatment is called for only under certain well-defined indications.

4. Where it is considered that diseased glands should be treated by deep x-ray therapy or the application of radium.

1. *Requires no further comment.*

2. *That all diseased glands should be excised.*

All is a big word and when we remember that to remove all the glands may be quite impossible, and also that, if their removal were possible, yet the term 'All glands' cannot include lymphatic vessels which may contain the tubercle bacilli, then this view is simply mentioned to be passed over. But again some may ask, do we want to remove these glands, which battle with those organisms that have passed the first line of defence—the tonsils and sub-mucous lymph tissue of the upper respiratory tract?

If the cervical glands do not become enlarged these organisms may proceed further and gain entry into the blood stream and produce widespread damage.

3. *Surgical treatment under certain well-defined indications.*—Contra-indications which might be mentioned are:—

(1) If the disease is blood borne.

(2) If distribution of glandular disease is haphazard and irregular which suggests a blood-borne infection.

(3) If the case has previously been submitted to incision and curetting.

(4) If the patient is in the first year of life.

(5) If axillary glands are affected; this points to infection of mediastinal glands.

Indication for surgical treatment

Points worth remembering are:—

(a) In children, ninety per cent of cases are the result of a lymphatic spread from a local

area of absorption, and for a considerable time the disease remains local and gross infection by the blood stream is a late complication.

(b) As we have no specific anti-bacterial agent to overcome the tubercle bacillus, the wisest course then is to remove the affected gland or glands before blood invasion occurs.

(c) It is of significance to note that the bovine type of tubercle bacilli is found in a proportion of cervical gland tuberculosis varying from 25 per cent in Germany to 90 per cent in Scotland and that the bovine type occurs uncommonly (1 to 2 per cent) in pulmonary tuberculosis*.

The proportion in Madras, so far as I know, has not been worked out.

(d) The cosmetic result. The scars following a well-planned operation, if carried out before caseation and suppuration have occurred, may be less disfiguring than those following natural cure, but statistics go to show that the results of natural cure are not so calamitous as some make out, and are by others considered superior to those of surgical excision.

The indications for surgery then may be considered to be—

(1) persistence of the disease in spite of conservative treatment;

(2) the slightest evidence of caseation.

Excision completed, then a course of ultra-violet therapy could do nothing but good.

If surgical treatment be deferred until caseation occurs, then excision of the glands will probably be impossible and curetting will have to be resorted to. The cosmetic result can then only be bad and recurrences may call for a repetition of the treatment.

Extensive involvement of the glandular area of a gross type demands not operation but intensive sanatorium treatment. Relatively rarely should it be necessary to have recourse to the mutilating operations described in textbooks, where an endeavour is made to remove all enlarged glands.

In America, surgical excision is described as a barbarous survival, and has been largely abandoned during the last 10 years.

4. *The treatment of tuberculous glands with deep x-ray therapy and with radium* has been carried out in the General Hospital here. Soft glands yield better and quicker results than do hard ones which require prolonged treatment, and respond better to radium than to deep x-rays. The dosage aimed at is 400r per course and from three to six courses are required. Naturally, if the glands have broken down, aspiration is carried out first. Radium in doses of 2 to 2½ mgms. per cubic centimetre of tissue has been used, applied in the form of a pad.

(Continued at foot of opposite page)

* Work in India has, however, shown that the bovine infection is extremely rare in gland tuberculosis in this country (*vide*, Liston and Soparkar, 1917, *I. J. M. R.*, 5, 19, and Ukil, *I. J. M. R.*, 20, 1209).—
Editor, *I. M. G.*

THE PLANNING OF TUBERCULOSIS INSTITUTIONS IN INDIA

By C. FRIMODT-MÖLLER, C.B.M., M.B.,
Ch.B. (Copenhagen)

Medical Commissioner, The Tuberculosis Association of India

Now that a new impetus has been given to the campaign against tuberculosis in India, and new schemes are being developed involving the building of clinics, hospital wards, sanatoria and ex-patients' colonies, for the prevention of tuberculosis and treatment of tuberculous patients, it will probably be of help to many if some general considerations are given for the planning of such institutions. This is specially necessary in order that the limited money available for such institutions may be used to the best advantage, taking into account the modern outlook on the disease and the particular conditions found in India.

Modern outlook

The whole conception of tuberculosis has altered in the last thirty years and this has had a marked effect on the planning of various institutions for combating the disease.

(a) *Emphasis on prevention.*—In earlier years the chief activity was the isolation and treatment of those obviously sick and in need of treatment, but now without minimizing the great importance of this side of the campaign, emphasis has been rightly laid much more on prevention. This involves the detection of very early cases, and even of those not yet showing clinical symptoms, and the tracing out and dealing with sources of infection, so that in western countries special buildings have been constructed for carrying out this side of the campaign.

(Continued from previous page)

The treatment is given in small weekly doses over a period of two to three months.

It should be stressed that excessive dosage may lead to rapid breaking down and thus the most propitious moment for surgery may be missed.

Glands which have broken down may respond to deep x-ray therapy, but naturally this depends on the extent of the suppurative process. The presence of a small sinus in the neck is no contra-indication to the use of x-rays but where caseation or secondary infection is present the treatment is not likely to be of value.

It is not possible to lay down definite rules to cover the treatment of all patients suffering from tuberculosis of cervical glands.

As one reads through the literature on this controversial subject, one wonders, with a writer on the subject, where common sense comes in, when the discussion reaches the stage of a Socratic dialogue.

(b) *Development of treatment.*—In earlier years advanced cases were either left in their homes to die or removed to isolation hospitals for the same end, and only very early cases were sent to sanatoria to live in the fresh air. While early cases still recover with as little special treatment as in former days, the majority of advanced cases are no longer left to die, because the development of treatment has made it possible to send many of them back to live a normal life. This modern treatment to be successful requires in the institutions facilities for extensive laboratory work, x-ray examinations, operative work, light treatment, and, much more, nursing. This has meant a complete change in the planning of a tuberculosis institution, whether it be clinic, hospital or sanatorium.

(c) *Infectivity and location.*—The emphasis on the infectious nature of the disease, which followed the discovery of the tubercle bacillus, led to a public scare and misunderstanding of the nature of the infectivity. This fear has not disappeared yet and frequently hinders and works against the stamping out of the disease in a certain locality, by forcing the tuberculosis institution away from the very place where it is really needed. A properly run tuberculosis institution is certainly not a danger to its neighbourhood provided that regulations are made preventing tuberculous patients coming from outside areas and living in the houses in the neighbourhood of the institution without proper control or treatment. Tuberculosis does not spread from an institution even in a crowded area, because the infectious nature of the disease is far different from a disease like smallpox or measles; it is not dangerous to be in the vicinity of a tuberculous patient. It has been proved that tubercle bacilli have a very short life outside the body in the open air, and are not carried by air or dust from one building to another in a living condition. This new knowledge of the infectivity of the tubercle bacilli has had its effect on the location of tuberculosis institutions, which can now be placed wherever they are most needed.

Influence of particular conditions found in India

In buildings concerned with the prevention and treatment of tuberculosis and the after-care of the tuberculous, there are certain common essentials all over the world wherever modern methods are being carried out, but these may have to be modified in form according to the particular conditions and customs of each country.

Two factors are of special importance in India, climate and the social customs, both showing wide differences in the different parts of India, so that what may be suitable for the north may be unsuitable for the south. Full details of the modifications cannot be given, but it may be said about the social customs that more provision has to be made in India for the separation

of the men's and women's sections in an institution than in Europe, and more provision for special wards with quite separate kitchens has to be made in India where there are such wide variations with regard to community, caste and particular customs and diets. Attention to these details is specially necessary in treating tuberculosis, as the treatment usually requires a long stay in the institution.

Types of Institutions in the tuberculosis campaign

Until recently there were three distinct types of institution in a tuberculosis campaign each with its own particular functions, namely, the clinic or dispensary, the tuberculosis hospital for advanced cases, and the sanatorium, to which was added in later years as a fourth type, workshops or else settlements of some kind for ex-patients. The outlook on the disease and the development of the treatment have caused a disappearance of the sharp distinctions in function and there is now a considerable overlapping, which is however not a wasteful overlapping, but a desirable one arising through co-ordination of work in the common effort against the disease.

In India, where tuberculosis institutions are as yet few in number and will be comparatively few for many years to come, this mingling of what were previously regarded as functions of separate institutions, must be emphasized and provided for in the planning of the institutions and the construction of their buildings, although the main purpose for which the particular institution exists must not be lost sight of.

Tuberculosis clinics

(a) *Purpose and general planning.*—The main purpose for which a tuberculosis clinic or dispensary should be planned and built is the detection of the disease and the prevention of its spread from the sources of infection detected. Such detection, specially in the very early cases, requires full laboratory and x-ray equipment.

In a large town, especially, it is necessary to have good facilities for registration, history taking and examination of many persons, by different methods, in a limited time. Proper arrangements should be made for filing and keeping the records, as a modern index system concerning the patients should be, in years to come, of the utmost importance in following up the patients when they move about in the city spreading the disease to new surroundings, and would enable the institution of efficient preventive measures.

The consulting room should have an examination cubicle connected with a dressing room. This last room should also be connected with the x-ray room to serve as an ante-room to this. Further, there should be one or two rooms for giving artificial pneumothorax treatment and various injections for thoracoscopic examinations

and cauterization of pleural adhesions, and for minor operations. It is essential to have close to the pneumothorax room a resting room in which the patients can rest after refills, in the same position in which they receive the refill, for about an hour before they return to their homes.

In India it will frequently be necessary to have two small wards for men and women, where a patient can be kept for just a few days if need arises, such as at the induction of an artificial pneumothorax, or if a special complication occurs during home treatment demanding close supervision, such as aspiration of air or fluid or controlling hæmoptysis.

There should be a dispensary room and also staff rooms and sanitary rooms for patients and staff. If possible a room for light treatment should be added.

Further there should be rooms for health visitors and a conference and committee room, because no clinic can do its full work unless there is a proper staff of health visitors and frequent conferences of these with the clinic medical staff and also with a care- and after-care committee to meet at the clinic.

(b) *Location.*—From what has been said of the purpose of a clinic it will be understood that its place is not on the outskirts of a town or city, but in the very centre of the population among which it is working. Ideally a clinic ought to be self-contained with its own x-ray, laboratory, etc., but if it is found necessary for financial or other reasons to locate a clinic close to an already existing hospital, it may be possible in the first years to use the hospital x-ray and laboratory and a few beds in one of the hospital wards. But, as the work succeeds and the clinic begins to occupy the place it should in the campaign against tuberculosis, it will be found necessary to have its own x-ray and laboratory and all other facilities required, and therefore the original plan must be made with the possibility for extension, and the location must be chosen with this in view.

(c) *Type plans.*—Below are given suggestions for type plans for a tuberculosis clinic for a city or large town and for a tuberculosis clinic in the compound of a *mofussil* headquarters hospital, where x-ray facilities are available.

It will be noted that passages are so arranged as to allow of plenty of air and ventilation, and that each room is accessible from passage or verandah.

Attention is drawn to the fact that this plan has completely separate sections for men and women which is an advantage in a large town. Therefore there are two examination rooms but only one x-ray room which must be used for both.

The examination cubicle is separated off by a screen or thin wall which need only be about 6 feet high. The reason for this cubicle is that the nurse can have the patient prepared while the doctor is talking to his relatives. Moreover, during the actual examination only the nurse

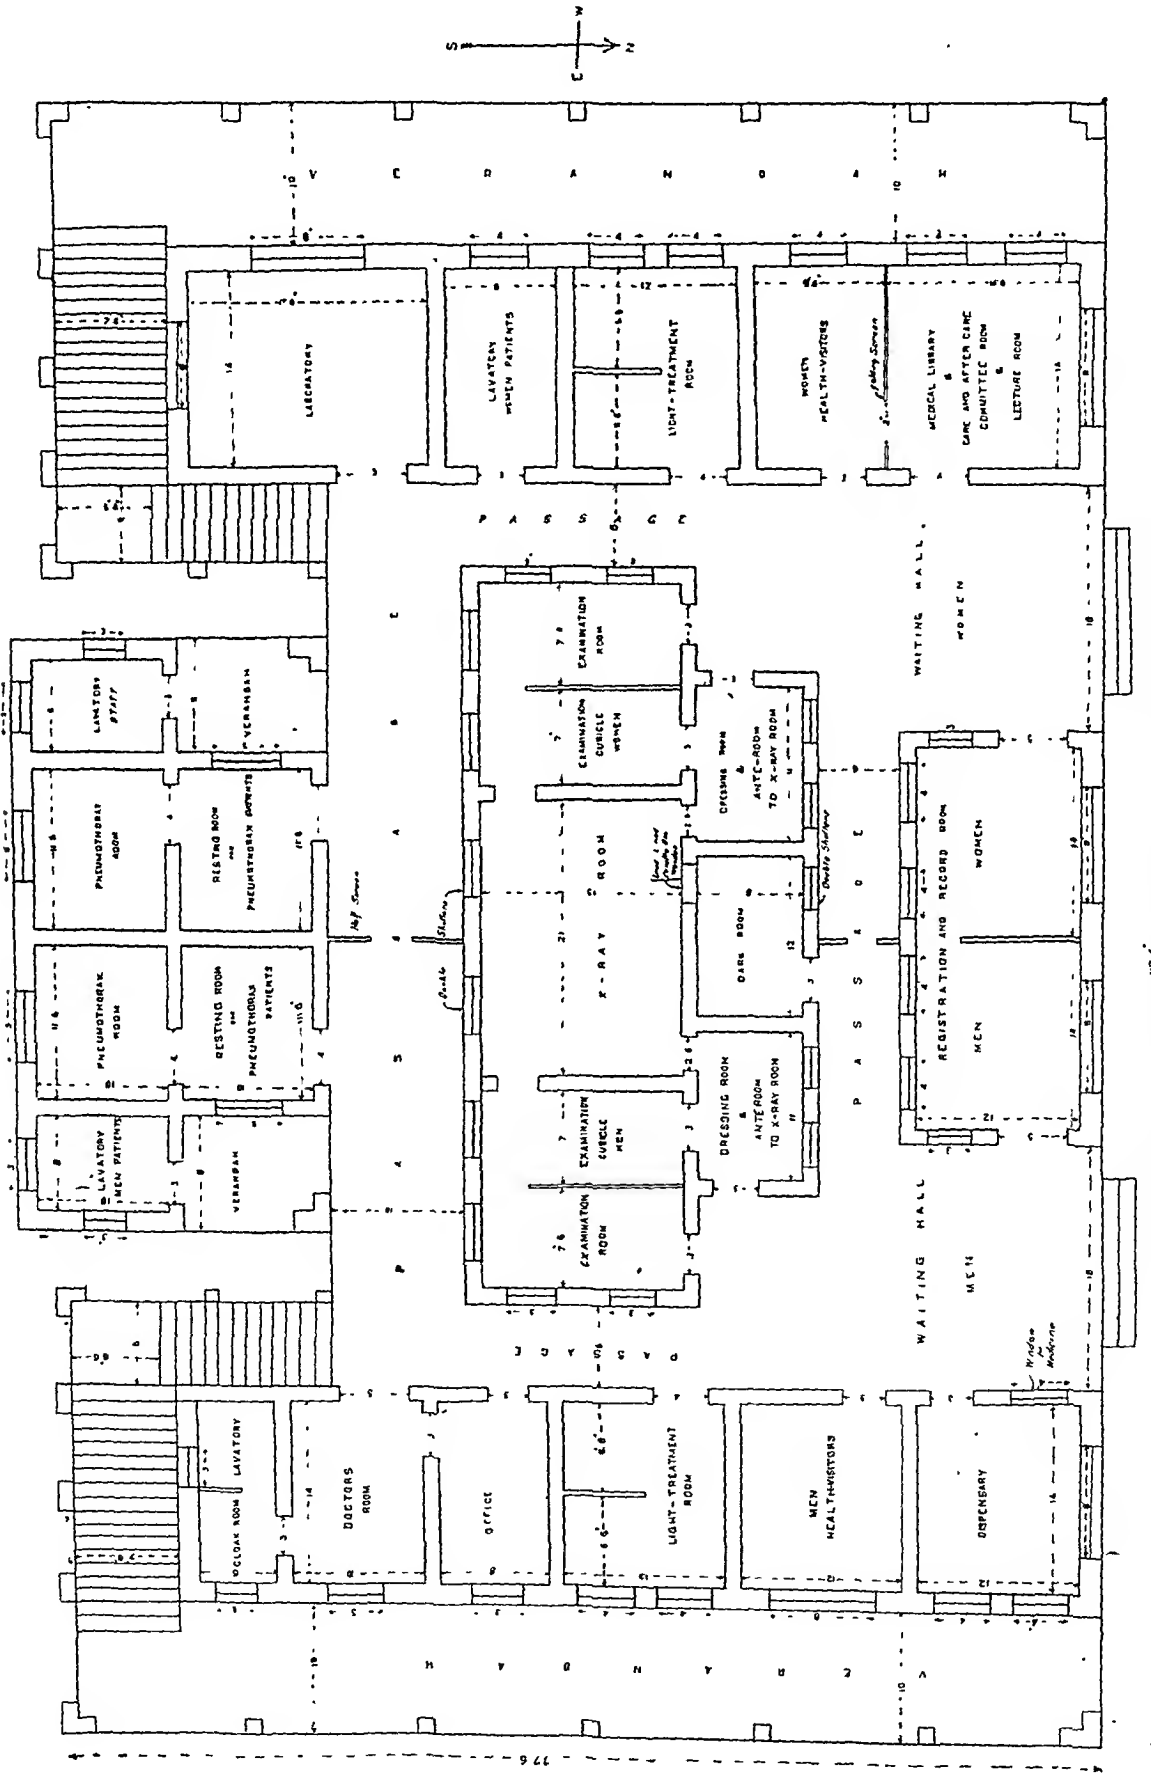

Fig. 1. Suggestion for a Tuberculosis Clinic in a large city. Ground floor. Scale, 1" = 5'.

x-ray room and another to it from the dressing room for women would be necessary. Another store room would have to be built, which will be best placed in connection with the nurses room. These various alterations and additions which would probably cost about Rs. 2,500 would complete the arrangements for installation of x-ray apparatus in the clinic.

Hospitals and sanatoria for tuberculous patients

In recent years the differences between a hospital for tuberculous patients and a sanatorium has largely disappeared, except as to location. A modern sanatorium admits advanced as well as early cases, because it has been found that many of the most advanced cases benefit strikingly when the modern treatment is carried out under sanatorium regime, in most cases even better than when such treatment is carried out in hospitals or private houses. Therefore, a sanatorium in these days should be as completely equipped as a good hospital for various kinds of surgical as well as medical treatment of tuberculosis in addition to having full facilities for x-ray and laboratory examination and light treatment.

The main difference now between a tuberculosis hospital and a sanatorium is that the hospital is situated either in or very close to a large centre of population irrespective of the climate and to a large extent of the general surroundings. A sanatorium in India should, however, be placed, wherever possible, in a place removed from the worst heat of the plains, as extreme heat is known to be detrimental to tuberculous patients. It should also be placed some considerable distance from a town in the open country with sufficient ground for graded exercises for the patients, and far enough away for the patients to be free from continual disturbing interruptions of relatives and friends and the enticements often adverse to a disciplined life so essential for a good recovery.

A tuberculosis hospital or sanatorium for about 50 beds should include the following buildings :—

General wards.

Special or private wards for paying patients.

Administration building containing examination room, x-ray, laboratory, light-treatment room, waiting room, office facilities, record room, dispensary.

Operating theatre with sterilizing and two post-operation rooms.

Quarters for two doctors.

Quarters for nursing superintendent.

Quarters for other staff.

Electric power plant, if current is not available from public supply.

Water supply.

Kitchen, store rooms (general, linen and medical).

Sewage system with septic tanks, if sufficient water is available.

Some details and suggestions for plans of some of the above buildings may be of interest :—

(i) *General wards*.—Below is a plan of a general ward of 18 beds which has been found to be very practical and suitable in South India.

The three main features of this ward are :—

(a) *Free circulation of air*.—The building has completely open sides, but the ends are protected by rooms at the corners and the ward should be placed in the direction of the prevailing winds, specially the monsoons, and not across. This arrangement prevents the rain beating in during the wet season. If excessive wind or rain does come from the sides protection can be obtained by letting down *chicks* between the outside verandah columns carrying the roof extension. These *chicks* should not reach to the ground but should stop about one foot from it, so that even if all the *chicks* are let down including those at the end passages, there will still be a free circulation of air. Any dust which may be thrown in is stopped by the raised basement and parapet wall.

(b) *Semi-privacy*.—The beds which are placed lengthways are separated by pillars about 1½ foot square. This breadth of pillar is not really necessary for carrying the roof of corrugated iron with country tiles, but it has an important additional function of providing semi-privacy for each patient, although he is in a general ward. A patient in the bed marked 'X' in the plan, can, when lying down, see only the two patients in beds 'Y' and 'Z'. This is of special importance when patients are together for a long period, often a year or more, as it minimizes causes for friction, which may more easily arise if the beds are placed side by side in one large hall. The arrangement of beds lengthways between broad pillars is also of very great importance when a patient is very sick or has hæmoptysis, both for his own sake and for the psychological effect on the others. A small screen placed on the inside only of the bed can then produce complete privacy without hindering the nursing or blocking the air.

(c) *Hygienic features*.—Between each bed across the centre of the ward is a distance of 9 feet, and there is the same distance from one bed head to the next. This is a safe distance from the point of view of infection from one patient to another; droplets of moisture containing bacilli produced in coughing fall to the ground in considerably less than 9 feet.

The water used in washing the ward is prevented by the parapet wall from flowing out under the roof extension where the sun could not beat on it and destroy the tubercle bacilli in these washings. Drains, not shown in the plan, carry the water to a septic tank and thus eliminate the possibility of dust-borne infection.

In order to have the wards as free as possible from anything that would prevent the keeping of them washed, clean and tidy, and free of things which would collect infected dust, corner

rooms are provided for the boxes and other possessions of patients. One corner room is reserved for a duty and medicine room for the nurse in charge of the ward.

Suggested modification for North India

The ward is too open for many places in North India both because of the prevalence of hot scorching winds in the summer, and the piercing cold in the winter. Instead of the *chicks* some more permanent form of protection should be provided, such as folding doors or large windows. In this case it would probably be preferable to have a flat roof over the verandah sections.

If for one reason or another closed wards of the ordinary hospital type are used, there must be provided either broad open verandahs in connection with the building or close to it where patients can lie on beds or easy chairs during the resting hours in the daytime.

(ii) *Special or private wards.*—In a sanatorium of 50 beds it is suggested that at least 10 of the beds should be in small separate wards or cottages with separate kitchens for each ward. This is partly to provide accommodation for a class of patients who would not care to be treated in the general wards and partly as a means of providing an income towards the maintenance of the general ward patients. The following is a plan for a very inexpensive special ward which in South India costs about Rs. 500 complete including equipment and kitchen. The ward is equipped with *chicks* or *tatties* on the three open sides and bamboo mats for shade extension, electric light and the following furniture:—taped cot with mosquito poles, table with drawers, ordinary chair and easy chair, food locker, sputum cup and sputum cup stand, shelves in the box room and commode. The separate kitchen has an outside measurement of 10 feet by 10 feet.

In addition to this cheap ward of light construction, two wards of better type more spacious and with more convenience are given below.

The building is a double ward but with complete separation for the patients and with separate kitchens. These are not shown in the plan; they are built separately at a distance of fifteen feet from the ward. The cost of this

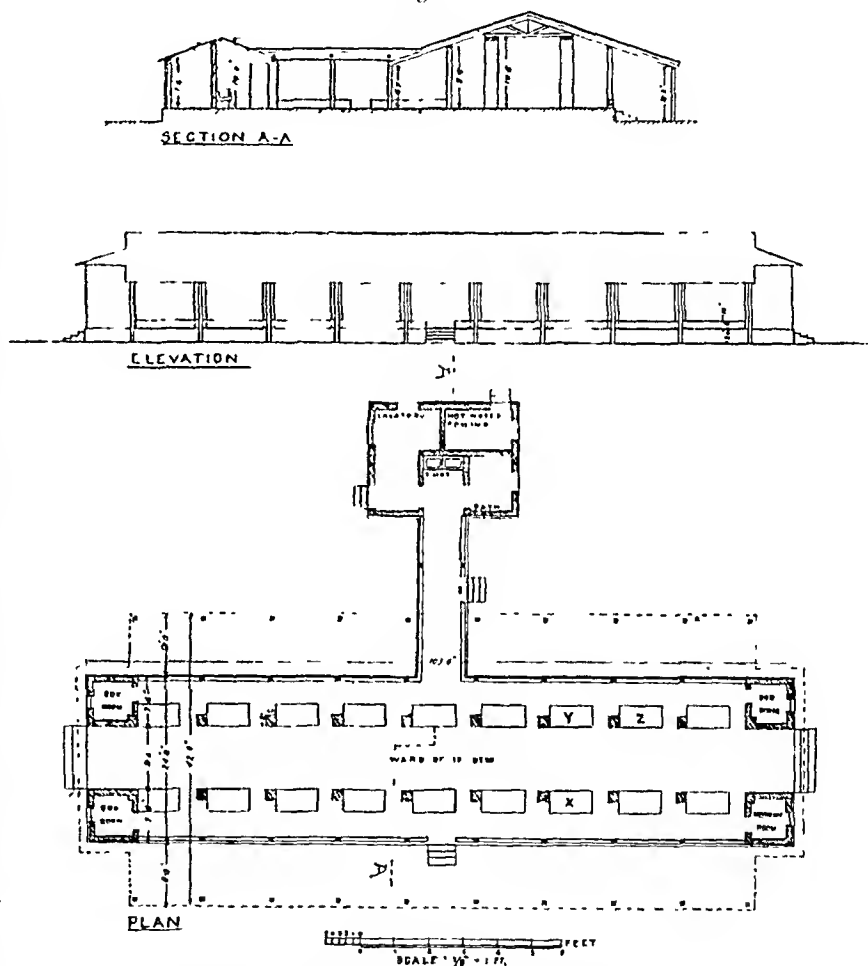

without equipment is about Rs. 3,000 in South India.

This is a larger but single ward with still more accommodation the construction of which costs only a little less than that of the double one.

The above wards are specially suitable for South and Central India, but in the extreme North more protection against the extremes of climate may be required.

(iii) *Administration building.*—This may be in one large building or it may be found more

convenient to separate some of the sections, varying with the local conditions, ground available, etc.

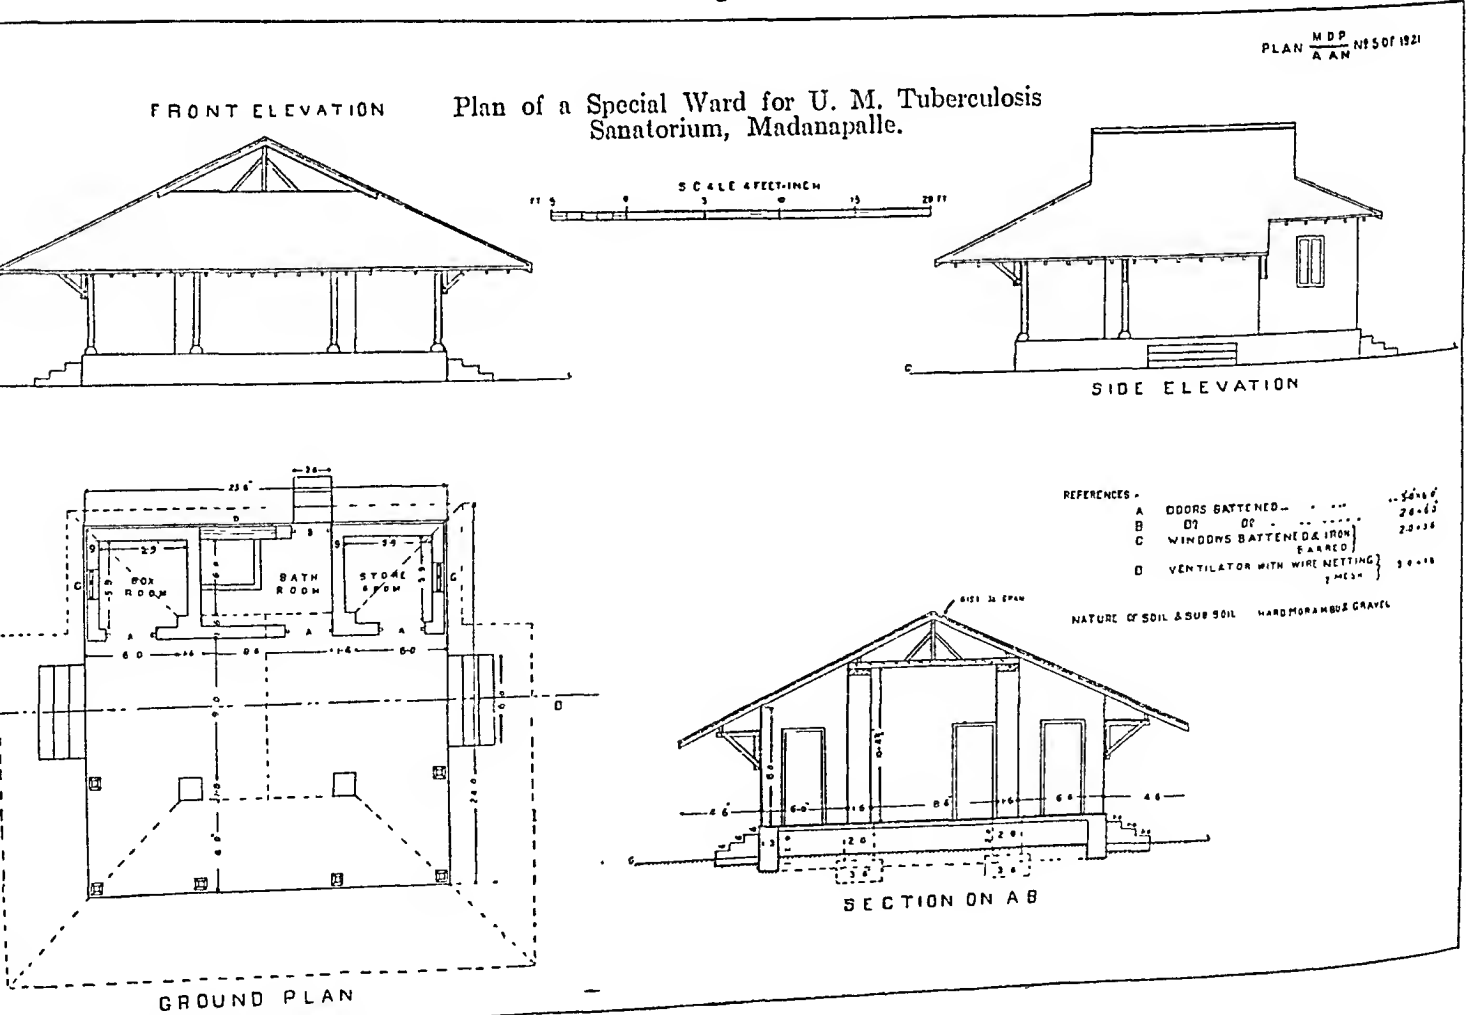

The examination room and x-ray room should, however, be kept together, as in modern methods of examination of tuberculous patients it is found most convenient to be able to screen during the examination. There should be made provision therefore to darken the examination room with curtains and the doctor to work in electric light so that his eyes will be accommodated to the screen without delay. The room for screening must have an efficient ventilation system and must be so constructed that it can

be completely opened up when not in use. In order that the accommodation of the doctor's eyes may not be spoilt for screening when patients enter or leave the room, there must be provided a dark ante-room. If the *x*-ray room is used for stethoscopic examination also, the *x*-ray machinery must be far enough away so as not to cause disturbance by noise.

In considering the laboratory, it should be understood that modern tuberculosis work requires a good many examinations, and the laboratory should be made large enough and have room for media preparation and sterilizing as well as for the usual examinations of sputum, blood, urine and stools.

The operation room should not have direct access from a corridor nor from outside but through some ante-room. It should also be capable of being darkened for thoracoscopic examinations. There should be two post-operation rooms as patients after a major operation, such as thoracoplasty, cannot be nursed in the general wards during the first few weeks. These rooms should also be used for patients after less serious operations, such as thoracoscopy, for a short period of about 24 hours, so that bleeding or any other complication may be quickly controlled. There should be access from these rooms to the *x*-ray, either direct or by a covered passage, so that the *x*-ray may be quickly and easily used for diagnosis or confirmation in the event of any complication occurring after operation.

Provision should be made for a medical library and record room, in addition to the other office facilities.

(iv) *Sanatorium or hospital grounds.*—The site selected must not be too small as there must be sufficient room for walks for patients, preferably separate for men and women, as the graded exercises, alternating with rest in bed, constitute the most essential part of the whole treatment.

The site should also be such as to allow expansion of the institution, should this be later needed. This possibility should be taken into consideration in planning the lay-out of the institution. For example, staff-quarters should not be built in a place where if the institution expands the new wards ought naturally to be placed, and special wards should not be built where general wards should later be located.

The distance between staff-quarters and the wards should not be less than 100 to 150 feet, both for the sake of privacy for the staff and also for quietness for the patients. If space allows the distance should be considerably more.

In locating the building it should be remembered that it might be necessary in later years to enlarge the administration building, and other buildings such as store rooms and kitchens; therefore sufficient space must be left so that if the extension is made, the buildings will not be cramped together preventing sufficient light and air access. Such extensions should also be borne in mind when roads are constructed,

avenues planted and gardens laid out. Well-laid-out avenues and groups of trees add much to the freshness of the air and protection from dust and give the necessary shade for outdoor life, while the beauty of flower beds has its share in encouraging the patients.

(v) *Staff-quarters.*—Details of staff-quarters cannot be given here but it must be remembered that sufficient medical and surgical staff must live in the grounds of the institution or very near at hand to be ready for emergencies which so often arise in this disease.

Ex-patients' colonies

Ex-patients' colonies are now more and more being recognized as an essential part of a successful tuberculosis scheme, but they should grow out of a sanatorium or tuberculosis hospital and be closely connected with it. The reason for this is that many of the ex-patients still need experienced medical supervision and care, in order to adjust the work to the capabilities of the ex-patient from the point of view of his health. Such an arrangement also gives an ex-patient confidence as he knows that skilled medical aid is at hand if required.

It is impossible to go into details about the planning of an ex-patients' colony as so much depends on the local conditions, the site available, the funds in hand and the work and industries chosen. But one thing can be said in general with regard to ex-patients' colonies in India, and that is that the planning of such colonies can be done on a far cheaper scale than in Europe and still have the desired result. The types of houses can be very simple, even of the ordinary village type modified for the purpose only by having partly open walls or large windows protected by wire netting, and with *pucca* floors. In addition to having the advantage of cheapness, they have the advantage that those who originally came from villages, if they later go back there, learn that they can live under village conditions and keep well. It is preferable to have a separate house for each member of the colony.

Conclusion

In conclusion, it is worth while remembering that in planning a campaign in India due consideration must be paid to already existing institutions, even if they are not ideal in construction from the modern standpoint. In many cases it should be possible to adapt, modify or reconstruct them so that they can be useful and thereby save considerable capital expenditure. Therefore, it is only right that existing institutions should review their plant to see if it fulfils requirements for effective work. In this the new Tuberculosis Association of India should be of greatest help as it can make available for all the experience of each, so that by general co-operation all may benefit and the whole standard of work and the means by which the work is done may be improved and be made more effective in tackling tuberculosis in India.

Indian Medical Gazette

SEPTEMBER

THE SPECIAL TUBERCULOSIS NUMBERS

THIS is the third year in succession on which we have issued a special tuberculosis number. It has always been the policy of this journal to maintain its 'general' nature in each number, and only in special circumstances to issue 'special' numbers. Special circumstances have, in our opinion, arisen.

Our reasons for issuing these special tuberculosis numbers are threefold. An organized and concerted effort is now being made by the whole nation to check the spread of tuberculosis, a disease which has hitherto not received the attention that its seriousness deserves, and we wish to play our part in this movement. We wish to emphasize the gravity of the position, that is, the extent to which the disease has spread amongst the population (this is well shown in the paper of Dr. Benjamin and his co-workers in this issue), to spread the knowledge that has been acquired by tuberculosis workers in this country on the methods of diagnosis and treatment, and on the organization for the control of the disease that are applicable in, and most suited to the needs of, this country, and at the same time by giving extracts from foreign journals to indicate some of the more important advances that are being made in our knowledge of tuberculosis in other countries. We have been particularly fortunate in being able to include amongst our contributors Professor Lyle Cummins who has not only acquired a great reputation as a phthisiologist in Great Britain but has made a special study of the disease in tropical and subtropical conditions; he was adviser to the South African tuberculosis research committee and later he visited Burma. He adds further support to the view already expressed by Indian workers that amongst many of the communities in India tuberculosis is a comparatively new experience; this means, as we have said before, that one cannot translate literally the knowledge gained by workers in other countries and apply it in India: considerable adaptation will in most instances be necessary before this can be applied in this country and therefore research must form part of any programme for the control of tuberculosis in India.

Lady Linlithgow's appeal, which was closed in the early part of this year, was a great success from two points of view: in the first place, a large sum of money was collected which will help to lay the foundations of a widespread anti-tuberculosis movement in India, and, secondly, the appeal focussed attention on tuberculosis, it made the whole population—ministers, members

of the assemblies, urban corporations, and district boards, village headmen, employers of labour, heads of families, and all who carry any responsibility for the health of others—tuberculosis-conscious. A perhaps not unnatural reaction to the enthusiasm of the early days of the launching of the appeal is now appearing and the people who helped to raise the fund are asking how the problem is going to be tackled, some in an interested and helpful spirit, others querulously and with a suggestion of hopelessness. 'What is the good', the latter say, 'of pointing to the successful campaigns in other countries, countries that are able and prepared to spend hundreds of pounds per tuberculosis death on sanatoria and tuberculosis hospitals, when we cannot afford as many pice for this special purpose?' But we shall not tackle the problem on the lines that they are doing it in western countries and we should not do so even if we had the necessary resources; we shall devise means suited not only to our limited resources but to the special conditions of the country. Whilst the balance is certainly in favour of the richer western countries, we have some factors that work in our favour, the sun, for example, and the relatively small proportion of our children that live under the conditions comparable to those of the grinding poverty and squalor of the overcrowded, sunless slums of many large European cities.

The control of the disease is so closely associated with the treatment of the existing cases that one cannot dissociate the two ideas. The anti-tuberculosis programme will of course include the building of sanatoria, up-to-date and well-equipped dispensaries, and after-care settlements, to act as models and to show what can be achieved under the most favourable conditions, but in such institutions, as with the funds available we could hope to found, scarcely one per cent of our patients could be accommodated, and we shall certainly not be content to leave matters there: something must be done for the remaining 99 per cent, and tuberculosis dispensaries, conducted on more modest but still we hope up-to-date lines, will have to be established, not only in every province and district but eventually in every *thana* or *taluk* in the country. This will be one of the problems to be solved by the conference of tuberculosis workers which is to be held probably in November this year in Delhi. Another very urgent problem which we hope will be discussed at this conference is the possibility of protecting the *mofussil*-bred recruit to industrial and urban areas where he is liable to contract, and living under unfavourable conditions to fall an early victim to, tuberculous infection. They should, we think, consider the possibility of using BCG vaccine for this purpose, but any experiments in this direction will have to be conducted cautiously and under the expert advice of a trained research worker who will see that the necessary conditions for the proper

assessment of the result of such an experiment are observed.

There is a tendency on the part of the medical practitioner to adopt a helpless attitude in the face of a diagnosis of phthisis and our second reason for publishing these special numbers is to show him that a very great deal can be done in the treatment of the individual case. What artificial pneumothorax did to improve the prognosis in the early and uncomplicated case a few years ago, thoracic surgery is achieving to-day in the more advanced case, and, although in these times of almost daily advances in chemotherapy no specific has yet been found, the outlook of the tuberculous patient is steadily improving.

The general public will take their tone, their attitude of hopefulness or helplessness, largely from the medical opinion of the day, and it is therefore important that medical practitioners throughout the country should have a proper appreciation of what can be done for the tuberculous patient in order that they may convey this spirit of hopefulness not only to their patients, and this of course is a very important matter, but also to the whole population, as in a problem of this kind general co-operation and support is essential.

Lastly, our third reason for publishing these special numbers is that we were offered the assistance and advice of an expert committee of the Tuberculosis Association of India in collecting and selecting the material for publication. For this number the committee consisted of Dr. C. Frimodt-Møller, Dr. A. C. Ukil, and Dr. B. K. Sikand, the secretary of the association. Though in principle the editor has the last word in the matter of selection of material for inclusion, in this number, we accepted the selections of the committee *in toto*, with the single reservation that if there was not room for all the papers in the special tuberculosis numbers, they would be published in the next issue of the *Gazette*.

The committee wishes it to be made clear that approval of these papers as suitable for publication does not necessarily carry with it approval of the principles enunciated therein. They do not wish the number to represent only their own points of view but rather those of all workers in India who by their position and achievements can be considered competent to express an authoritative opinion. It should perhaps be added that the function of the committee ceased when they forwarded the papers to us; the work of arranging and 'editing' the material was naturally left entirely in our hands.

The two previous special tuberculosis numbers have not only been very popular in this country (this has been shown by the number of extra copies that have been sold), but have attracted considerable attention outside India and we have received a number of appreciative letters regarding them from prominent tuberculosis workers

in other countries. This success would be quite impossible without the wholehearted co-operation of others and the editor take this opportunity of thanking the individual contributors, the editorial committee of the Tuberculosis Association of India—especially Dr. Ukil to whom he has appealed repeatedly for advice on technical points—and the publishers of this journal who have generously allowed us a considerable number of extra pages in this issue, for their co-operation in the preparation of this year's special tuberculosis number.

L. E. NAPIER.

'TUBERCULAR' AND 'TUBERCULOUS'

THE English language is not static. Words and phrases that are 'correct' to-day may be 'incorrect' to-morrow, or fifty years hence. So that when one uses the word 'correct' in this connection one should add the date and say 'correct in 1939', or it is perhaps safer to avoid the word 'correct' altogether and say 'current English usage'. Whilst this is true of the English language in general, it is particularly applicable to 'medical' language. Almost daily a discovery is made that may necessitate the introduction of a new word; there are other medical advances that make words meaningless or alter their significance completely, so that a well-established word may become obsolete over-night.

Prior to 1882 the adjectives 'tubercular' and 'tuberculous' were used more-or-less synonymously and meant 'consisting of or of the nature of tubercles'. In 1882 the tubercle bacillus was discovered, and it was found that while some 'tubercles', tubercular or tuberculous lesions, were caused by the tubercle bacillus, others were not, and by common consent the two adjectives took on different meanings.

The adjectival suffix *-ar*, from the Latin *-aris*, carries the meaning, 'of the kind of', 'of the form of', whereas *-ous*, from the Latin *-osus* implies rather 'of the nature of', so the former was applied to lesions consisting of or of the form of or covered with tubercles or nodules, and the latter was reserved for specific lesions caused by the then-newly-discovered tubercle bacillus, now known as *Mycobacterium tuberculosis*. Thus, we have 'tubercular syphilides' and 'tubercular leprosy', nodular lesions caused by the organisms of syphilis and leprosy, respectively, but 'tuberculous ulcers' and 'tuberculous meningitis', caused by the specific organism of tuberculosis. To obviate misunderstanding, it is surely better, where there are two words each of which might convey two meanings, to reserve one word for one meaning and the other word for the other meaning. Whilst this special use of these two words does not rest on an unassailable etymological basis, there can be no objection to it on etymological grounds and what is far more important these words have the sanction of established usage.

However, there are many writers who do not observe this distinction but use the two words indiscriminately, often alternating them by way of 'elegant variation'. This we think is a pity and, in this journal, whenever the writer's meaning is clear we use our editorial privilege and alter the suffix to conform with 'current English usage'.

We have not taken this step without reference to authority. We feel that we could not do better than appeal to the *Oxford English Dictionary*. The following are relevant quotations from this authority :—

TUBERCULAR

1. *Nat. Hist.*, etc. *a.* Of the nature or form of a tubercle. *b.* Having or covered with tubercles, tuberculate.

2. Of, pertaining to, caused or characterized by, or affected with tubercles.

Allbutt's Syst. Med. VIII, 805 Tubercular syphilide—the term tubercular used above refers solely to the gross infiltration of the skin causing raised nodules, and has no relation to the tubercle-bacillus.

b. spec. In reference to tuberculosis, or the tubercle bacillus; now technically replaced by *tuberculous*, *q.v.*

But as the discovery of the bacillus was made known only in 1882, the earlier examples of the word, though actually descriptive of the results of the action of the bacillus, did not refer to it, but to the presence of tubercles.

TUBERCULOUS

1. *Path.* Pertaining to or produced by tubercles; consisting of or the nature of tubercles; affected with tubercles.

2. Since 1882, almost always used *spec.* in reference to the tubercle bacillus, or to tuberculosis, and thus technically distinguished from *tubercular* in the general sense.

We also quote Stedman's Medical Dictionary, as a second, technical authority :—

Tubercular. 1. Relating to or marked by tubercles or nodules on the skin or in the tissues, tuberculated, nodular. 2. Tuberculous. *t. leprosy*, see under *leprosy*. *t. syphilide*, cutaneous gummata.

Tuberculous. Relating to or affected by tuberculosis. It is the better practice, following the analogy of the Latin termination *-aris* and *-osus*, to restrict the term *tubercular* to conditions marked by the presence of (non-specific) tubercles or nodules, reserving *tuberculous* for conditions marked by an infiltration of (specific) tubercle, thus we may speak of *tubercular*, or nodular, leprosy, and *tuberculous* disease of the skin, or lupus.

KING GEORGE THANKSGIVING (ANTI-TUBERCULOSIS) FUND

A REVIEW OF THE ACTIVITIES FOR THE YEAR 1938-39. BY DR. B. K. SIKAND, M.B., B.S., D.P.H.

THE 1938 report of the King George Thanksgiving (Anti-Tuberculosis) Fund on tuberculosis work in India was the last report to be issued by that body. The Fund was along with King-Emperor's Anti-Tuberculosis Fund incorporated into the Tuberculosis Association of India on the 23rd February, 1939. The setting up of the central and provincial state tuberculosis associations as a result of Her Excellency's appeal has given a renewed life to the whole campaign against tuberculosis and marks a new and a very important step forward in tuberculosis activities in India. Those who have been responsible for the administration of the King George Thanksgiving (Anti-Tuberculosis) Fund

since its inception in 1931 will find in this new development the fulfilment of their desire for a more effective control of tuberculosis in India. The Fund continued to follow its established policy of organizing the training of workers, providing propaganda material, helping educational campaigns, while it maintained an information bureau, and co-ordinated preventive activities in the provinces. The following is a summary of the activities of the Fund for the year 1938:—

HER EXCELLENCY THE MARCHIONESS OF LINLITHGOW'S APPEAL FOR THE KING-EMPEROR'S ANTI-TUBERCULOSIS FUND

The most important feature of the year so far as tuberculosis in India is concerned was the successful result of Her Excellency's appeal. The collection of funds has been associated with such a wide educational campaign that 1938 will be remembered as a special anti-tuberculosis year. At headquarters the closest co-operation was maintained with the appeal office. A grant of Rs. 1,000 was given by the Fund committee for showing the 'Papworth Film' and in the provinces and states all the provinces and states sub-committees helped a great deal in the propaganda for the collections of funds.

THE TUBERCULOSIS ASSOCIATION OF INDIA

Preparations were made in 1938 for the formation of a Tuberculosis Association in India. At the request of Her Excellency the Marchioness of Linlithgow the King George Thanksgiving (Anti-Tuberculosis) Fund appointed two sub-committees: (1) a technical committee of medical men with expert knowledge of the tuberculosis problem in India, and (2) a constitution-drafting committee to consider the policies and planning of the proposed All-India Tuberculosis Organization to be formed as a result of the King-Emperor's Appeal. The technical recommendations on being accepted by the Fund committee were submitted to Her Excellency and issued from the appeal office as a note on the tuberculosis problem in India for the guidance of provincial organizations. The proposed constitution for the central and provincial tuberculosis associations was later in consultation with the provincial authorities approved by Her Excellency and the Tuberculosis Association of India was legally registered on the 23rd February, 1939.

TRAINING OF TUBERCULOSIS WORKERS

Forty-five doctors were selected out of 300 applicants and received training at two courses held at the All-India Institute of Hygiene and Public Health, Calcutta (January-February 1938), and Mayo Hospital, Lahore (November-December 1938). The selection was as far as possible equitably distributed over the different provinces and states and due regard was paid to the candidates' past experience in tuberculosis. As in previous years no admission or tuition fees were charged and the Fund paid the out-station candidates single return second-class fare up to a maximum of Rs. 100.

The greatest difficulty of preventive work for the tuberculosis clinic is the lack of properly trained tuberculosis health visitors. The Fund tried to meet this difficulty by organizing a special six months' course at Delhi with the help of the Silver Jubilee Tuberculosis Hospital and the Lady Reading Health School. Though in theory it was agreed that fully-qualified nurses with special training in tuberculosis are essential for this work it was nevertheless necessary in the peculiar conditions in India where trained nurses are not available for this work, to select 10 matriculate candidates over 21 years of age out of 17 applicants. The course opened on the 16th January, 1939. The candidates received Rs. 20 per mensem with free furnished quarters but the employment and pay of the candidates is a matter left entirely to the provinces and states who deputed them for training.

EDUCATIONAL ACTIVITIES

The education of the public in regard to the causation and prevention of tuberculosis and the

stimulation of individual initiative have been the fundamental objectives of the Fund's educational activities, which have been aided by the excellent publicity campaigns organized by the King-Emperor Appeal Committees.

The provincial and district committees have carried convincing messages to the public through posters, leaflets, health exhibitions, health songs, whereas a wider range of education has been provided by the radio from some centres.

The educational activities from the centre have been directed mainly towards creating contacts with and stimulating interest of individuals and organizations interested in public welfare. It was emphasized during this year that the best way of attracting public opinion is through the educated section of the community and that short special courses are a very useful form of activity. Short courses on tuberculosis among organized groups, like teachers, university students, St. John Ambulance Brigade, Overseas Divisions, and nurses have been organized with the help of the authorities concerned and all necessary help was given from the Fund's headquarters.

The Fund maintained a stock of suitable educative material in various languages. Ten thousand two hundred and twenty-six pamphlets and leaflets and 8,678 posters and charts were distributed free through educational institutions, public libraries, maternity and child-welfare centres, health exhibitions and other social organizations. Sales of stocks registered a marked increase, 11,273 pamphlets and 53,506 posters and charts being sold as compared with 4,166 pamphlets and 14,014 posters and charts in 1937.

The following new literature was issued during the year:—

1. 'What a Teacher should know about Tuberculosis', in English, Urdu and Hindi.
2. 'Prevention of Tuberculosis', in Hindi.
3. 'A dangerous teacher and the lessons he teaches about Tuberculosis', in English.

Twenty-one slides were sold and the educational films in tuberculosis were in great demand. Closest co-operation has been maintained with organizations like the maternity and child-welfare bureaux, women social organizations, life insurance companies, who were interested in tuberculosis work in their own sphere of activities and all these have been very good allies in our cause.

CO-ORDINATION OF PROVINCIAL ACTIVITIES

To meet the difficulty of early diagnosis of open cases amongst poor patients the Fund committee approached the local governments through its provincial/state committees, to provide free sputum examination facilities for poor patients on the recommendation of a qualified medical practitioner, at all public health laboratories and district and taluq hospitals. The Government of India was also requested to commend this proposal to all provincial governments. The governments of Madras, Assam and Sind have accepted this proposal and have issued orders accordingly. In Delhi, Baroda, Jodhpur and Ajmere-Merwara arrangements already exist where facilities for examination are available. It is expected that other Provincial Governments will also accept this proposal.

SPECIAL TUBERCULOSIS NUMBER OF THE 'INDIAN MEDICAL GAZETTE'

As in the previous year, the *Indian Medical Gazette* published a special tuberculosis number; in this matter they were assisted by a publication committee of the King George Thanksgiving (Anti-Tuberculosis) Fund who collected and selected the papers for the special number. This contained articles by prominent tuberculosis workers in India dealing mainly with the prevention of the disease and the methods which are being or might be adopted to deal with this problem in India. This proved very popular and was very welcome at a time when the subject of tuberculosis was of absorbing interest, not only to medical men but to all concerned with India's welfare.

HASSAN MASUD SUHRAWARDY MEMORIAL ANTI-TUBERCULOSIS CHALLENGE SHIELD

The shield competition which is organized to stimulate interest in anti-tuberculosis organizations, received 9 entries against 5 entries last year. The shield was awarded to Delhi for the best anti-tuberculosis efforts made in 1937.

INTERNATIONAL UNION AGAINST TUBERCULOSIS

The Fund continued to be a member of the International Union and maintained the closest co-operation with its activities. With the help of the Union Dr. B. S. Ramanna, the Fund's nominee, was selected for a scholarship at the Carlo Forlanini Institute. This is the third occasion on which a nominee from India has been selected for this foreign scholarship, the previous awards being made in 1933 and 1934.

A new relationship was established with the Imperial Bureau of the Empire Conference on the Care and After-Care of Tuberculosis. The objects of this body are:—

- (1) To supply and receive information on tuberculosis activities.
- (2) To help visitors with information and introductions for a study of tuberculosis.

Several nominees from the provinces took advantage of these facilities.

ORGANIZING SECRETARY'S TOURS

The organizing secretary toured the Central Provinces, Assam, and the Punjab. He addressed several meetings and met medical and public health authorities and stressed the urgency and need for active and sustained measures for the prevention and control of tuberculosis. He also met railway, and tea and oil industry authorities and suggested schemes suitable for the need of each area and discussed in detail the line which would give a new orientation to the existing medical machinery towards preventive efforts against tuberculosis.

PROVINCIAL AND STATE BRANCHES

The sixteen provincial and state branches received various grants from the centre aggregating to Rs. 25,500. The reports from these bodies show a good progress in educational and preventive campaigns in general. The running of tuberculosis clinics has come to occupy a prominent place in the activities of the active branches. When the Fund started activity in 1930 only a few clinics existed in India. The Fund has helped the opening and maintenance of such clinics in a few provinces and states. There are now 60 such clinical units working, spread over India. The reports from some are very heartening and are excellent illustrations of the success which can be achieved by tuberculosis clinics.

Special Article

THE PROGNOSTIC IMPORTANCE OF BLOOD EXAMINATIONS IN PULMONARY TUBERCULOSIS

By R. M. BARTON, M.A. (Oxon.)

Pathologist, Union Mission Tuberculosis Sanatorium, Arogyavaram, near Madanapalle, South India

A GREAT many blood examinations may be done for tuberculous patients, but only a few of them are of real value from the point of view of prognosis and guidance during treatment. Examination of the hæmoglobin content of the blood, of the number and condition of the red cells, examinations for malaria parasites and for syphilis, are important and, wherever possible,

should have their place in the cure of the tuberculous, as the treatment of a complication has often a great influence on the progress of a patient, but all these examinations are not directly connected with the disease of tuberculosis, nor do they show anything of the progress of the disease. Even the absolute white cell count is of little help, as the majority of patients show figures coming within the normal range, and usually only the most advanced patients with considerable cavity formation show any marked and significant increase. Modern work also shows that there are considerable variations in the total number of white cells in the peripheral circulation even during a single day.

Sedimentation test and differential counts

There are, however, two examinations which are of the utmost importance: the sedimentation reaction and the differential count. It is admitted that neither of these is specific for tuberculosis, and they can, therefore, by themselves not be used to establish a diagnosis, but in the absence of other ascertainable disease they may strongly suggest a tuberculous condition, and when tuberculosis has been diagnosed can provide the physician with a wealth of information about the condition of his patient, specially when the examinations are made at fairly frequent intervals.

The sedimentation test has been carried out in our laboratory since 1926, at first only on admission of a patient, and occasionally later during treatment, but as its usefulness came to be more understood, regular monthly examinations came to be made for all patients.

A routine differential count was begun for all patients on admission in 1925, using Ehrlich's classification of cells, but this count proved disappointing in the help it gave. There was a small amount of prognostic information gained, as a study of a group of 1,700 tuberculous patients showed a gradual increase of neutrophils and decrease of lymphocytes with the

in the neutrophils. Apparently the reserve of mature neutrophils in the body is rather small, and whenever there is a sudden call for more, due to disease or injury, young or immature neutrophils are produced rapidly in the bone-marrow and sent out into the circulation. Therefore, an examination of the neutrophils, with regard to age, was interpreted as being able to show the severity of the strain on the body caused by the disease or injury, a 'shift to the left', i.e., an increase of less mature cells being interpreted as an adverse sign, and 'a shift to the right', i.e., an increase in the more mature cells as a good sign. The original Arneht count is not much used now, but a modification of it has been advocated by some tuberculosis workers, e.g., Houghton (1932) called the von Bonsdorff count, in which the total number of lobes are counted in 100 consecutive neutrophils, the normal average being about 270.

Schilling differential count

Other workers have found the Schilling count to be not only simpler and time-saving, but also to give information just as good as the Arneht or similar counts. In the Schilling count, the neutrophils are divided into segmented and non-segmented groups, the latter group being subdivided into three: so there are

- (i) segmented neutrophils,
- (ii) non-segmented neutrophils,
 - (a) stabkernige or stabzellen,
 - (b) metamyelocytes or jungkernige or jugendformen and
 - (c) myelocytes.

Metamyelocytes and myelocytes are not normally found in the peripheral circulation, although occasional cells may be found in various infections, and under abnormal conditions numbers may be found in tuberculous as well as other diseases. An example will illustrate the value of the Schilling count, as compared with the Ehrlich count:—

		Neutrophils	Stab.	Segmented	Eosinophiles	Mast cells	Lymphocytes	L. mono-nuclears
Ehrlich	..	60	4	1	29	6
Schilling	..	60	48	12	4	1	29	6

stage of the disease on admission and with the ultimate prognosis as shown by results on discharge, but the variations in each group were so marked that the Ehrlich count could not be used as a guide to prognosis with any great certainty (Frimodt-Møller and Barton, 1933).

It was only in 1930, when we began to study the neutrophils, from the point of view of maturity, that we found in the differential count information of real significance and help in tuberculosis. Arneht was the first to emphasize and attempt to interpret clinically the changes

Judged by Ehrlich's method, the differential count is a good one, but judged by Schilling's method it is a bad one, as 48 out of 60 neutrophils are immature, instead of 3 to 5 (or possibly up to 10), showing that there is a considerable strain on the patient. This is a type of count frequently found in tuberculous patients.

It must be emphasized here that occasional differential counts by untrained workers using the Arneht-Schilling count, or a modification of these, are of little value. The counts should be done by those with considerable experience,

who have reached a standard of judging segmentation of cells, which is not liable to variation.

Technique

(a) *Blood smears.*—The blood smears and the blood for the sedimentation test are taken simultaneously, and in order that a standard technique may be used, the examinations are always made between 9 a.m. and before the main morning meal at 11 a.m., to avoid variations which might be caused by meals, although it is doubtful whether there is really a so-called 'digestion leucocytosis'. The smears are made with the drop of blood from the syringe needle used in taking the sedimentation test. Houghton (1936) showed that smears made from venous blood are less subject to variation than smears made from capillary blood. Thin smears are made on good, clean slides by drawing the blood behind the spreader slide (not pushing in front), holding the spreader slide at an angle of about 30°, and using only light pressure. The smears are made by one member of the laboratory staff. As far as possible, therefore, the conditions are the same for all smears. Leishman's stain is used, and in normal routine examinations 200 cells are counted, and the counting is ordinarily done by one member of the laboratory staff. The method of making a differential count has been a matter of discussion, and different techniques have been suggested to compensate for any possible uneven distribution of leucocytes in the smear. The method used in the writer's laboratory is to take a line from end to end of the smear in three or four parts of the smear, top, middle and bottom; the edges of the smear are not taken, but the end of the smear is included; cells are not counted at the beginning of the smear if they cannot be easily and accurately identified, specially with regard to segmentation of the neutrophils, owing to the smear being a little thick. With the above precautions it has been found in practice that a good and even distribution of cells is usually obtained and that 200 cells are sufficient for normal routine counting.

(b) *Sedimentation test.*—The sedimentation test is carried out according to *Westergren's technique*. Into a 2 c.cm. record, or preferably all-glass syringe, 0.4 c.cm. of sterile 3 to 8 per cent sodium citrate in distilled water is drawn, and blood is then drawn into the citrate solution up to the 2 c.cm. mark, from the median basilic or other arm vein, no tourniquet being used, but only light pressure by the hand of an assistant. This makes a dilution of 4 to 1 of blood to citrate. After making the smear as mentioned above, a little air is sucked into the syringe, and the blood and citrate are well mixed and left in the syringe until the test is set up in the laboratory later in the morning. At that time the blood citrate solution is again well shaken, put into a small test tube and drawn up into a Westergren sedimentation tube marked in millimetres from 0 to 200. The sedimentation tubes are placed vertically in a rack, and after 1 hour the reading is taken of the upper level of the red cells.

If Westergren tubes are not available, 1 c.cm. pipettes graduated 1/100 to the tip may be used, but in order that readings may be comparable the height of the 1 c.cm. column should be about equal in all the pipettes, and preferably about 200 mm.

Blood index in tuberculosis

When the differential count and the sedimentation test are studied in relation to the clinical condition of the patient, it will be found that information they give about the condition of the patient is not always identical, the sedimentation rate (S R) seeming to be a little slower than, for example, the stabkernige percentage in showing any change in the patient's condition. Various methods of assessing the blood picture

have been suggested with a view to obtaining a single figure in which change may be seen at a glance. A tuberculosis index published by Frimodt-Møller and Barton (1933) has been in use in this institution since 1932, and is made up by the addition of four factors, an increase in each of which is generally an adverse sign, and a decrease a favourable sign. The four factors are:—

- (1) Neutrophile-lymphocyte ratio obtained by subtracting the lymphocyte percentage from the neutrophils percentage (N-L).
- (2) Mononuclear-lymphocyte ratio obtained by subtracting the lymphocyte percentage from the large mononuclear percentage (M-L).
- (3) The percentage of neutrophils, which are immature, obtained by dividing the stabkernige percentage by the total neutrophile percentage and multiplying by 100 ($\frac{\text{Stab.}}{N} \times 100$).
- (4) The percentage of sedimentation rate in one hour, using Westergren method ($\frac{S R}{2}$).

The formula is

$$(N-L) + (M-L) + \left(\frac{\text{Stab.}}{N} \times 100 \right) + \frac{S R}{2}, \text{ or more simply } N+M + \left(\frac{\text{Stab.}}{N} \times 100 \right) + \frac{S R}{2} - 2L.$$

This index is not a mathematical assessment of the patient's condition, but experience of its use for seven years in over 18,000 examinations in about 3,400 patients has shown that it is very valuable and generally gives more reliable information about the patient, than any single part of the differential count, or the sedimentation rate, taken by itself.

With this index there is a wide range of readings varying from a normal of about -20 to +20 to a reading of as much as 250 in very advanced tuberculosis. An index of above 150 is usually a bad prognostic sign. A variation of about 10 in the index is not considered of much significance; such a difference can easily be caused by minor and insignificant changes in the percentage of the blood cells (or sedimentation rate) possibly due to technique or to small changes in the patient's condition.

Importance of both differential count and sedimentation test

Many workers employ only the sedimentation test, but much information may be missed if the sedimentation test alone is used, and sometimes it may be even misleading. The following is an illustration of this:—

V. J., woman. Admitted 1st July, 1937. Died 27th November, 1937. Stage III, C.

In this patient, reliance on the S R alone would have given a misleading idea of the patient's condition, but

The x-ray photo showed a slight improvement on 3rd February, 1939, as compared with that taken on

Date of blood examination	Total neut.	Myel.	Jungkern	Stab.	Segm.	Eos.	Mast.	Lymph.	L. mono.	S R	Index
2-7-37	79.0	1.0	1	56.0	21.0	6.0	1.0	7.0	7.0	83	184
2-8-37	90.5	0.0	0	72.0	18.5	2.0	0.5	2.5	3.5	76	207
1-9-37	91.5	0.0	0	76.5	18.0	0.5	0.0	3.5	1.5	50	195
1-10-37	95.0	0.0	0	63.0	32.0	0.0	0.0	1.5	3.5	20	172
15-11-37	90.0	0.5	0	72.0	18.0	0.5	1.5	4.0	3.5	6	169

the condition was not hidden in the differential count. Shortly before death it is not unusual to find the sedimentation reaction failing, but it is unusual to find the failure extending over several months, as here.

Moreover, there are many cases which show a comparatively good sedimentation rate either before treatment begins or more usually soon after treatment is instituted, but whose lesion is still active, as shown by the blood count, clinical condition and x-ray.

Blood examinations in pulmonary tuberculosis treated by non-surgical methods

In patients who are treated by ordinary routine sanatorium treatment, with or without drugs, but without artificial pneumothorax or other surgical treatment, there is usually a rapid improvement in the blood picture, if the treatment is going to have a good result, specially if the blood picture is bad on admission. The following is an illustration :—

S. M., male, aged 12. Admitted 10th April, 1938. Discharged 1st September, 1938. Stage II, B. 'Arrested.' T. B. + (stomach-wash water).

Date of blood examination	Total neut.	Myel.	Jungkern	Stab.	Segm.	Eos.	Mast.	Lymph.	L. mono.	S R	Index
11-4-38	90	0	0	45.0	45.0	1.5	0.0	2.5	6.0	94	188
3-6-38	50	0	0	27.5	22.5	1.5	0.5	44.5	3.5	79	30
6-7-38	57	0	0	26.0	31.0	0.5	0.0	40.5	2.0	19	33
4-8-38	42	0	0	16.0	26.0	11.5	1.5	39.5	5.5	8	11

A patient getting no good result, or whose condition is deteriorating, shows this in the blood, as seen in the following case :—

N. B., woman. Admitted 6th December, 1938. Died 10th March, 1939. Stage III, C.

7th December, 1938, but the blood showed a slight worsening of the patient's condition, and death took place one month later.

When the patient shows a comparatively good blood picture on admission, with an index of below 50, there is often but little change during treatment.

Blood examinations during artificial pneumothorax treatment

Blood examinations are important during the course of artificial pneumothorax treatment as a control of the treatment and as a guide to the continuation or change of the treatment.

A successful artificial pneumothorax is quickly followed by a rapid improvement in the blood picture. The following are examples :—

P. C. S., male. Admitted 16th June, 1938. Discharged 24th September, 1938. Stage III, A. Artificial pneumothorax left begun 24th June, 1938 (see 1st table, p. 576).

In the following case, as there was extensive disease in the upper half of both lungs on admission, artificial pneumothorax treatment was delayed for some months.

N. R. P., male. Admitted 17th September, 1937. Discharged 3rd January, 1939. Stage III, B (see 2nd table, p. 576).

With routine sanatorium treatment sanocrysin was given. The general blood picture did not improve much, only the S R showing reduction. On 23rd

Date of blood examination	Total neut.	Myel.	Jungkern	Stab.	Segm.	Eos.	Mast.	Lymph.	L. mono.	S R	Index
7-12-38	73.5	0.0	0	48.0	25.5	1.5	0.0	20.5	4.5	99	152
11-1-39	70.0	0.5	0	56.5	13.0	2.0	0.5	23.0	4.5	86	153
3-2-39	72.5	0.0	0	49.5	23.0	0.5	0.0	15.0	12.0	91	169
3-3-39	91.5	0.0	0	63.0	28.5	0.0	0.0	4.0	4.5	90	201

February, 1938, artificial pneumothorax was begun on the left side, together with a second course of sanocrysin. This was followed by a gradual improvement of the blood picture, except for an interruption

allowed a little walking, but the examination in February 1938 showed again a set-back; five days later there was a rise of resting temperature to 101°F., and screening on 23rd February, 1938, showed a little fluid.

Date of blood examination	Total neut.	Myel.	Jungkern	Stab.	Segm.	Eos.	Mast.	Lymph.	L. mono.	SR	Indcx
17-6-38	76	0	0	42.5	33.5	0.5	0.0	17.0	6.5	26	118
30-7-38	63	0	0	18.0	45.0	1.5	0.0	33.0	2.5	18	37
25-8-38	61	0	0	21.5	39.5	2.5	0.0	33.5	3.0	3	35
20-9-38	54	0	0	22.0	32.0	7.5	0.5	32.0	6.0	14	44

in August, due to a pleural effusion, which began in the middle of July.

The following is an interesting example of a study of the blood in artificial pneumothorax treatment.

T. O. P., male. Admitted 25th September, 1937. Discharged 24th November, 1938. Stage III, B.

After that, both the clinical condition and the blood picture improved rapidly, and the patient was discharged as 'much improved'.

The following is an example of only a little improvement being effected by an artificial pneumothorax, due to the presence of adhesions, but rapid improvement following a thoracoscopy and cauterization of the adhesions.

Date of blood examination	Total neut.	Myel.	Jungkern	Stab.	Segm.	Eos.	Mast.	Lymph.	L. mono.	SR	Index
17-9-37	68.0	0	0	48.5	19.5	0.5	1.0	24.0	6.5	75	136

Artificial pneumothorax left began 5th October, 1937 (see 3rd table, on this page, below).

Although artificial pneumothorax was continued with apparently plenty of air space, from October to December, after a very slight initial improvement, there appeared to be a set-back. X-ray screening showed considerable bulging of the mediastinum; consequently the pressure in the artificial pneumothorax side was reduced by injecting only 500 c.cm., and later 400 c.cm., instead of 800 c.cm. This was followed by an immediate improvement of the blood picture. Fever disappeared, and the patient was

P. T. A., male. Admitted 6th July, 1937. Discharged 11th September, 1938. Stage III, B (see top table, p. 577).

Artificial pneumothorax was begun on 13th July, 1937. Thoracoscopy and cauterization was done on 21st August, 1937, followed by a slight effusion, which delayed the blood change in the September examination. After that there was rapid improvement.

The blood examinations quickly show if there is development of disease in the contralateral lung during artificial pneumothorax treatment.

The following is such an example in a woman patient who had initial improvement following artificial pneumothorax on right side (see 2nd table, below):—

Before the examination on 3rd March, 1938, the patient was walking 3 furlongs morning and evening, but after that examination he was put to rest, because of the blood change. Five days later, he complained of ano-rectal pain, and examination showed an abscess

An x-ray photo in April 1939 showed definite infiltration in the left side; the previous photo at the end of January did not show a change. The change in January was probably due to fluid in the right side, but later, when the fluid was absorbed, there was only a slight improvement in the blood, soon followed by a deterioration, due to disease beginning and spreading in the left side.

Change in blood picture before clinical onset of complications

It can be stated as a general rule that a change in the patient's condition is shown in the blood picture before it is shown in the clinical condition of the patient, or in the x-ray picture. The routine blood examinations at the sanatorium at Arogyavaram are done at monthly intervals. This is a fairly long interval necessitated by the limits of the laboratory staff and consideration for the patient, and therefore frequent examinations do not show the coming complication which may have a rapid onset. But frequently they do; and the following are two examples:—

M. P. B., male. Admitted 8th November, 1937. Discharged 7th September, 1938. Stage II, A.

forming, which was incised and drained on 25th March, 1938. The blood examination showed the change before any clinical symptoms were reported.

The following is an example of blood change coming at the beginning of a pleural effusion:—

S. V. C., male. Admitted 12th July, 1937. Discharged 25th March, 1938. Stage III, B (see top table, p. 578).

On 23rd July, 1937, artificial pneumothorax was induced on the right side, and a course of sanocrysin was given during October and November 1937. The blood picture improved steadily until March 1938. The April examination showed a sudden change for the worse, and the patient, who was walking 3 furlongs morning and evening, was kept to the ward, and then 10 days later the patient began not to feel well, and slight fever came. On 22nd May, 1938, x-ray screening showed fluid in the pneumothorax side. After two aspirations the patient improved, as also the blood picture, and walking was again given, finally he was discharged 'much improved'. Here again the blood picture showed a change before the clinical condition.

These particular complications were not prevented by the warning given by the blood

difficult to say for certain that such a breakdown would have occurred if, for example, the exercise had not been curtailed, but experience in other cases, where sufficient notice has not been taken of the blood change, leads us to think so.

The following is an example of such a case (also illustrating other changes):—

N. K., woman. Admitted 4th December, 1937. Discharged 20th January, 1939. Stage III, B.

producing satisfactory results, and if the patient is doing graded exercises, they can be continued or increased.

Conclusion

In the blood picture of a tuberculous patient, when both the differential count, using Schilling's differentiation of the neutrophils, and the sedimentation test are employed at regular intervals, there is an extremely valuable aid to the physi-

* Intervening examinations with no important changes omitted for the sake of space.

Artificial pneumothorax was begun on 10th December, 1937, and because of adhesions thoracoscopy and cauterizing on 19th January, 1938. This was followed by good improvement shown in the blood, x-ray and clinical condition. On 3rd March, 1938, the blood showed a change to the worse, and screening on that day showed fluid in the pneumothorax side. There was again improvement until June, when the blood again showed a change for the worse. The patient's walking was halved for one month, and the next blood examination showed an improvement. Here the reduction of exercise probably forestalled a temporary breakdown. The change in the blood picture in August was produced by a 'cold' with pain in the chest and throat.

Experience has shown that a change in the blood picture for the worse, other than minor changes, must be treated with respect, and an attempt should be made to ascertain the cause, if possible, by clinical, physical and x-ray

examinations. But the blood picture must be interpreted along with the results of the clinical and physical examinations of the patient, and the x-ray examination, although sometimes it may give information as to the improvement, or the opposite, of the patient, before these other examinations.

Summary

(1) Of many blood examinations done for tuberculous patients, the sedimentation test and differential counts are of special importance as regards prognosis and as a guide during treatment.

(2) Only a differential count in which the neutrophils are sub-divided according to

maturity, is of real value in tuberculous patients.

(3) The technique for Westergren's sedimentation test and the Schilling differential count are given.

(4) A blood index for combining the information provided by the sedimentation test and Schilling differential count is given.

(5) The necessity for doing the differential count as well as the sedimentation test is pointed out.

(6) The value of blood examinations in

(a) Pulmonary tuberculosis treated by non-surgical methods.

(b) Treated by surgical methods is shown with illustrations.

(7) The blood picture shows the onset of complications and usually shows a change in the patient's condition, before the clinical condition or x-ray or physical examination.

(8) In the blood picture made up of the Schilling differential count and the sedimentation test, there is a valuable aid to the physician, to be used along with the other methods of examination of the patient.

PROCEEDINGS OF THE INAUGURAL GENERAL MEETING OF THE TUBERCULOSIS ASSOCIATION OF INDIA, HELD ON THE 29TH MARCH, 1939, AT THE VICEROY'S HOUSE, NEW DELHI

Proceedings

HER EXCELLENCY THE PRESIDENT addressed the meeting as follows:—

It is with a feeling of pride and gratitude that I address you to-day. Pride at the partial achievement of my hopes and gratitude for the help which I have received from all over India. I say partial purposely as I had aimed at a larger sum than the amount collected of over 79 lacs. However, as I have so often said in the last few months, the most important result of my appeal in my opinion is the permanent establishment of the Provincial and State Associations which will be carrying on the work long after my appeal has been forgotten.

My gratitude I give in full measure to the Governments, to the business men, to private individuals, to the Press and last but not least, my most sincere thanks are due to Sir Ernest Burdon, General Bradfield, to Colonel Chamier and to Mr. Badenoch who have been towers of strength to me all through. I support General Bradfield in the hope that the Red Cross who have been so generous and helpful throughout should always keep in close touch with the new Tuberculosis Association. It is no easy job to run an appeal of this magnitude without a certain amount of friction, but I think I can truthfully say that it has been conspicuous by its absence.

When you are dealing with a country of the size of India and when so much has to be done by correspondence, it is inevitable that a few misunderstandings should arise, but I am happy to say that they were of a very minor nature and that it was possible to clear them up with satisfaction to all sides. I think too that it has been abundantly proved that all shades of thought, all political denominations, and all religions can unite for an object which is humanitarian and one where the enemy is a universal enemy. Tuberculosis does not select its victims from the rich, from the poor, from the Hindu, from the Muslim or from the Christian; it attacks the whole community, and therefore the whole population must present a united front. The problem is a big one and is one which must be met in a big way. Do not, I beseech you, in the future let petty differences or individual ambition deter you from your course. Do what you have to do without any thought of personal gain or any wish for reward. Let your reward be the salvation of your people and the elimination of a dread scourge.

It is only in this spirit I feel sure that real progress can be made.

You all have before you a copy of the policy of the Central Association which makes no mention of the after-care settlement so close to my heart. It makes no mention of it as at the moment there is not sufficient money to finance it, but I think most of you know from constant repetition on my part what my dream is. You have many eminent doctors in this country who know a good deal more about the technical side of tuberculosis than I do, but I have seen a good deal in England from my connection with the Papworth Settlement of the psychological side, and it has been borne in on me more and more since I started this appeal how necessary an after-care scheme is. At the moment the anxiety as to what is to become of them when they leave the sanatorium is bound to have an adverse effect on the peace of mind of the sufferers and therefore will retard their recovery. As you can imagine I have a good many letters from tuberculosis patients, some begging me to get them into a sanatorium as they cannot afford the fees, others telling me that they have been discharged and advised to get light jobs and asking me to find them. They realize as we all do that they cannot compete in the open market with healthy men and women, and one is forced to ask oneself what can they do. If we face facts the answer is there—nothing, unless there comes into being a settlement for tuberculous patients where they will be put to a trade and where they can earn a living wage, and where their families can be brought to make a home for them. I know that some people out here think that I am suggesting the impossible, but there are two very eminent doctors—one an Indian and one a European—in this country who think as I do. I do not quote their names as I did not ask them leave to do so and I fear that it might involve them in voluminous correspondence which they would find it difficult to cope with, but they are I know trying to devise ways and means of starting a scheme of after-care.

As to the methods of dealing with tuberculosis through clinics, this is a method which has been universally accepted and is being carried out in many places already with considerable success. A great many more are wanted and will be built with their staffs of doctors and health visitors as occasion arises, and as money is forthcoming and I would like to reiterate the fact that the simplest style of building is all that is necessary and I do deprecate large sums of money being spent on elaborate structures.

The advice of the technical expert at the centre will be available at all times to those who wish for information in this respect. He will be there to help in any way which may be required. You may rest

assured that he will be an expert in every sense of the word as the committee with whom the appointment rests will not be satisfied with anybody but the best.

One of the paragraphs in the papers alludes to the avoidance of duplication of effort. I feel sure that you will agree that this should be avoided at all costs. It is such a waste of money, and the only way that duplication can be avoided is by constant communication between Provinces, States and Centre. I hope that the rules and regulations for the Centre will once for all lay the bogey of interference or control by the Centre. I should like you to look upon yourselves as one large family with the Centre in the position of a parent. When a family grows up and disperses to various corners of the world the parents like to be kept in touch with the lives, the thoughts, the experiences of their family. With the interchange of letters many new ideas and a different outlook on the same subject let in many rays of light to the advantage of both. This is the relationship which I want to see between Centre and Provinces and States. Don't think that it is beneath your dignity to communicate with the Centre or that it is a confession of weakness. The Centre may get much valuable material from the Provinces or States in the same way that they in their turn may get much from the Centre. Co-ordination and good fellowship should be the watchword of the new Association. The half-way mark of my stay in India has been passed, and the time is not far distant when I shall be leaving. I will take with me many happy memories, and perhaps the happiest of them all will be the thought of the foundation of the Tuberculosis Association of India, with the immense possibilities for good which lie before it.

I wish you all the best of good fortune in your endeavours and I ask you to keep always before you the fact that new discoveries and new methods appear very rapidly, and that unless you keep yourselves up to date, you will never achieve the position which I would like you to have in the world fight against tuberculosis.

Major-General E. W. C. Bradfield, C.I.E., O.B.E., K.H.S., I.M.S., Chairman, Central Committee, in making a statement on the present position of the Tuberculosis Association of India said:—

YOUR EXCELLENCY, LADIES AND GENTLEMEN,

It is my duty this evening to make a business statement; to explain the constitution of the Tuberculosis Association of India, and the methods which can be employed to attain its objects.

We have succeeded the King George Thanksgiving Fund, which since 1929 has administered the funds handed over by His Excellency Lord Irwin, to be used for preventive measures against tuberculosis, and we are heirs to the valuable pioneer work of the older organization. The Tuberculosis Association of India was duly registered on the 23rd February under the Societies Registration Act (No. XXI of 1860) and has assumed control of the funds, management and secretarial staff of the King George Thanksgiving (Anti-Tuberculosis) Fund.

The constitution of the new Association has been liberally designed not only to ensure that every use can be made of any recognized activity able to influence the prevention and cure of tuberculosis, but also that Provincial and State Associations may be independent of any central control and may be governed by their own constitution. An important rule (No. 11) of the Central Association provides that all members of Provincial and State organizations and other affiliated bodies are eligible to become members of the Association without payment of any fees, and one of the first duties placed upon the Central Committee was to define this membership in accordance with the proposed bye-laws of the Association. I say proposed bye-laws because they have been left for final confirmation by the full committee which I hope will be in being immediately after this meeting. It is obviously impracticable to have too many individual members of an organization which embraces the whole

of a country the size of India, and at the same time undesirable to fix an arbitrary limit to numbers. After studying the organization and constitution of similar bodies in other countries the sub-committee who examined this problem felt that the method of representation adopted by the International Union against Tuberculosis could be suitably adapted to our requirements. The International Union, in which we succeed to the membership allotted to the King George Thanksgiving Fund, is a federation of 43 independent National Tuberculosis Associations. Each National Association is represented on the Union by two councillor members, though countries with more than 10 million inhabitants are entitled to appoint an additional councillor for each additional 5 million or part thereof, but the total number of councillors for any country cannot exceed five. The position which, I suggest, should be established in our Indian Association is that the members of our central association should be really the Provincial, State or other affiliated bodies themselves acting through their representatives. As these associations may not be legal persons in all cases there is difficulty in making them members as such. It is therefore proposed that this membership shall be exercised by each affiliated body who will appoint or elect two of their members as their representatives, to act for them at any general meeting. They may act individually or under instructions from their association. The condition of affiliation was, as you know, waived in the case of to-day's meeting in order that the meeting might be as representative as possible.

In addition to those members whom I have just mentioned, members of the Central Committee automatically become members of the Association and there are nine foundation members who were signatories to the Articles of the Association, but who will not be members of the committee.

The Central Committee has so far been represented by a few *ex-officio* and co-opted members (the latter retired automatically before to-day's meeting) who, although possessing under the rules and regulations the powers of a full committee, did not wish to take upon themselves more than was essential to put the organization in motion. They have therefore deferred final decision on all important questions till the committee is constituted on a wider basis than at present.

Under (x) it is proposed that five members, three from British India and two from Indian States, shall be elected to the Central Committee by all the affiliated bodies. This election will be arranged by the secretary's office. Each Association will be asked to nominate one member and voting papers will be submitted by post. Under (xi) the Central Committee proposes to co-opt Mr. Mitra, Solicitor to the Government of India, as their legal representative and to utilize the remaining four vacancies to give representation to those Provinces, etc., who do not secure a seat at to-day's election.

When we have completed these elections and co-options the strength of our Central Committee will be 28 (including Her Excellency the President) and I think you will agree that this is a reasonable number.

A note on the policy of the Tuberculosis Association of India has been circulated to the Provinces and States explaining the attitude of the present committee towards the future work. Some of the branches will in the beginning have more need of advice than others? As the organization develops we hope that the Association will work as one co-operative body deriving real benefit from the interchange of ideas and experience among its members.

I need not enter into details because you can read the printed statement for yourselves. Our responsibility is to promote co-operation in all efforts designed to prevent or treat tuberculosis, and by expert advice, propaganda and research to stimulate the interest not only of our affiliated association but of all authorities, whether government, municipal or private. We seek the co-operation of all organizations engaged in promoting public welfare and as Chairman

of the Indian Red Cross Society I should like to mention here that the Red Cross is very anxious to retain a connection with the Tuberculosis Association and in some way to continue an association which has been so valuable in the past. I am certain too that Provincial and State bodies will welcome such a co-operation.

Your Excellency, I desire to offer to you on behalf of the members of the Tuberculosis Association of India our congratulations on the success which has attended your efforts in raising the King-Emperor's Fund and on the inauguration of our new Association and its affiliated bodies throughout India. In these days the only sure thing is the uncertainty of to-morrow, but the Tuberculosis Association has been established with a sound foundation, and with the willing co-operation of which we are assured, we are confident that success will be achieved in attaining the objects for which your vision has schemed.

Mr. A. C. Badenoch, Honorary Treasurer of the King-Emperor's Anti-Tuberculosis Fund and the King George Thanksgiving (Anti-Tuberculosis) Fund, made a statement on the financial position.

THE CONFERENCE OF THE INTERNATIONAL UNION AGAINST TUBERCULOSIS, 1939

THE XIth Conference will be held at Berlin from 16th to 20th September, 1939. 'Leading specialists who have concerned themselves with tuberculosis both from scientific and social view point will take the opportunity to lecture on the results of their researches and experiences, and contribute thereby to the collaboration which in the end serves the indispensable understanding of the nations'. The Reichs-Tuberculose-Ausschuss, Berlin, is organizing the Conference and Dr. Otto Walter has been elected the President, Dr. Heinrich Grass the General Secretary and Heinz Slangen the manager of the Board. The reigning President of the Union is Prof. Lopo De Carvalho, and Prof. Fernand Benzacon, the General Secretary.

The Conference will discuss the following subjects:—

Biological subject—The problem of the virulence of the tubercle bacillus.

Clinical subject—The value of systematic examinations for the detection of tuberculosis in subjects over 15 years of age.

Social subject—The rehabilitation of the tuberculous.

MEDICAL POST-GRADUATE COURSE IN TUBERCULOSIS

THE Tuberculosis Association of India with the help of the Surgeon-General, Madras, is holding a medical post-graduate course in tuberculosis from the 2nd to the 31st October, 1939, both dates inclusive. The training from the 2nd to the 14th October will be imparted at the Medical College, Madras, and allied tuberculosis institutions there, and for the period 16th to the 31st October at the Union Mission Tuberculosis Sanatorium, Arogyavaram, near Madanapalle. The medical commissioner of the Tuberculosis Association of India and other tuberculosis specialists will deliver lectures on various aspects of the subject, in addition to practical demonstrations, etc.

[The applications for this class had to be submitted before 1st September, and the 25 vacancies will now have been filled.]

THE RED CROSS

HIS MAJESTY THE KING-EMPEROR has been graciously pleased to sanction the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem:—

As Officers

Lieutenant-Colonel Edward Slade Goss, M.C.
Lieutenant-Colonel Ronald Robert Candy, C.I.E.
Lieutenant-Colonel Norman Briggs.

As Associated Officer

Lieutenant-Colonel Ambuj Nath Bose, O.B.E.

As Associate Serving Brother

Major Dharendra Nath Gupta.

Current Topics

Anti-tuberculosis Work in the Dutch East Indies

By DR. O. WISSE

(Abstracted from the *Bulletin de l'Union Internationale Contre la Tuberculose*, Vol. 16, January 1939, p. 78)

THE campaign against tuberculosis in the Dutch East Indies is of recent origin. Owing to the improved methods of diagnosis the disease is more easily identified and contrary to the general belief the disease, especially pulmonary tuberculosis, has been found to be widespread among the Javanese, the Chinese and the poorer classes of Eurasians. Soldiers, civil servants, peasants, merchants, domestics and numerous women contract the disease. In spite of more interest taken in the campaign against this social scourge, all the work accomplished in the dispensaries and the sanatoria has produced no effect on the course of the disease in the East Indies. This gloomy result is due to the utterly indifferent attitude of the natives towards the disease, their mistrust of western methods of treatment, and hence the lack of co-operation on their part and the inability to adopt the more modern methods of tuberculosis schemes, owing to the low financial condition of the millions of infected natives. In consideration of this last condition the author suggests that more attention should be paid to those anti-tuberculosis measures that cost little. The number of sanatoria should be limited and greatest attention

should be paid to dispensaries which are in closer contact with the population where inexpensive ambulant treatment should be carried out, and to special tuberculosis hospitals which are indispensable for the effective working of the dispensaries for the purpose of observation, control, and survey. Rest cure can be followed at home under the supervision of the dispensary. The author recommends auxiliary methods, such as public-health propaganda, the improvement of popular diet and the increase of national prosperity. The institute for the improvement of popular diet is doing excellent pioneer work in this line. Regarding treatment, the author recommends that native patients need not be transferred to high altitudes as the climate of Java is not unfavourable for the tuberculous. He emphasizes the necessity of submitting a large number of patients to collapse therapy, but at the same time remarks that in Java the number of phthisiologists is not adequate to supervise such treatment.

The Work of a Tuberculosis Unit in East Africa

By H. N. DAVIS

(Abstracted from the *Tubercle*, Vol. XX, November 1938, p. 76)

THE work was started in 1927 in the district of 'Moshi' in the Northern province of Tanganyika with

an experimental sanatorium containing 25 beds without any facilities for x-ray, or A-P treatment. Visits were made to each village and tuberculosis cases were brought to the sanatorium. Later on, the number of beds was increased to 35 and tuberculosis dispensaries were established (whose number became 10 in 1932). Tuberculin was used both for diagnosis and treatment. Tuberculin treatment was found definitely harmful in marked tuberculin reactors.

Arrangements for x-ray and collapse therapy were made in 1932 and marked improvement resulted in acute exudative cases which hitherto had received medical treatment only. The hospital became more popular and the number of beds had to be increased to 60. Gradually, other operative measures for collapse therapy were introduced.

In the following period of 5 years collapse therapy was given to 261 patients—84 per cent received A-P therapy only and 16 per cent purely operative treatment.

Of the 261 cases, 23 could not be traced and the results of treatment of the remaining 238 at the end of 5 years may be summarized as follows:—

Minimal 51 cases—8 per cent died and 92 per cent alive of which 83 per cent had working capacity.

Advanced 187 cases—49 per cent died and 51 per cent alive of which 58 per cent had working capacity.

Total 238 cases—40 per cent died and 60 per cent alive of which 67 per cent had working capacity.

A comparison of results between collapse therapy and medical treatment alone in advanced cases showed that the mortality rate is about three times higher in the latter group. As regards after-care supervision, a village settlement was started in which families are living and carrying on normal agricultural pursuits in healthy surroundings under medical supervision.

Tuberculosis in Cyprus

By N. D. BARDSWELL

[Abstracted from the (i) Review of an Interim Report. *British Journal of Tuberculosis*, Vol. XXXIII, 1939, p. 68, and (ii) Final Report. *Tubercle*, 1938-39, Vol. XX, pp. 97 and 165]

To make a survey of the tuberculosis problem in Cyprus, the author made a tour throughout the six administrative districts of the island in 1936-37 collecting all available data and he published an interim report on the incidence and means of control of tuberculosis in Cyprus. This preliminary enquiry was undertaken under these lines: (1) conversation with representatives of all sections of the community; (2) attempts to discover the present condition of all tuberculous cases known to the medical authorities; and (3) tuberculin testing (by the percutaneous method of Moro) of samples of the child population. Certain provisional conclusions were made, the most important of which was that the tuberculosis problem in Cyprus is not so widespread and grave as had been anticipated by the people and government, the tuberculosis mortality being estimated at about 2 per 1,000, and the incidence of positive tuberculin reaction being about 6.5 per cent in village children and 8.2 per cent in town children.

To confirm these conclusions a second visit was made in 1937-38. This investigation was made with two objectives in view: (1) An intensive study of tuberculosis in one of the six administrative districts—the Larnaca district—to determine the incidence and mortality rates, the distribution and character of the disease and the factors favouring its spread; (2) the establishment and organization of a tuberculosis dispensary in Larnaca to serve the town and its associated 58 districts in order to bring under observation all cases of tuberculosis in the district and all available members of households exposed to infection in the past or at the present time. The dispensary was made the centre from which all investigations were carried

out. The inquiry was made under the following different lines:—

(1) The tuberculin testing and examination of the whole school population of towns and villages.

(2) An inquiry into and examination, if alive, of all cases of tuberculosis since 1931, whether notified or not and a study of their environmental and economic conditions.

(3) The systematic tuberculin testing and examination of as many contacts as possible, whether alive or dead. An x-ray was included in the examination when practicable.

(4) Testing and examination on similar lines of contacts of children who gave positive reactions during the school survey.

(5) The systematic study of the death registers of the towns and villages since 1931, to determine the probable annual mortality from tuberculosis.

(6) Attempt to investigate the home conditions according to a home investigation form which contains enough materials for study, of the sociological aspect of tuberculosis.

The chief conclusions drawn from this intensive survey of a selected limited area of this island are as follows:—

(1) The incidence and mortality from tuberculosis, pulmonary and non-pulmonary, in the district is low and is rather less than expected after the preliminary survey. It is estimated that there are about three cases of pulmonary tuberculosis per 1,000 living and the average annual death rate is 0.9 per 1,000.

(2) In its distribution, tuberculosis is sporadic and to a large extent familial, cases being usually traceable to intimate contact with another case in the family with positive sputum.

(3) There is no bovine tuberculosis and the virulence of tubercle bacilli from patients in Cyprus is similar to that of bacilli from patients in Britain.

(4) Infection in childhood is an important factor in the spread of the disease, as a high percentage of child contacts who react positively shows radiological evidence of intra-thoracic tuberculosis.

(5) The Cypriot has a high resistance to tuberculosis, succumbing only to long-continued and massive infection. The Greek-speaking races are somewhat more resistant than the Turk. Chronicity with slight constitutional disturbance is the outstanding clinical picture of the disease. Bronchiectasis appears to be common and is often mistaken for tuberculosis. Acute pulmonary tuberculosis is rare. These characteristics are probably due to some degree of inherited resistance to tuberculosis and to the local conditions, such as climate and the habits of the people (open-air life).

(6) The standard of living and social development of the people is low. Poverty is almost universal. There is no correlation between poverty *per se*, and the incidence of tuberculosis. The nutrition of the people appears to be adequate and normally malnutrition is not an important epidemiological factor. Tuberculosis is often introduced into a family or village from the town or abroad.

The experience gained in the other districts during the preliminary survey suggests that a survey of the other five districts on similar lines would give parallel results.

(7) Tuberculosis in Cyprus, though low in incidence and benign in type, is difficult to control owing to its uniformly scattered distribution, lack of transport facilities, ignorance of the people, the unsatisfactory housing conditions (mostly single-roomed houses) and lack of experienced medical and nursing personnel.

The author suggested that the most effective tuberculosis administration would be dispensaries in various parts of the island under the direction of a whole-time tuberculosis officer and a staff of trained home visitors as nurses, some beds for advanced cases, a small sanatorium unit for the more favourable cases and organizations for the relief and care of tuberculous households.

Prevention and Treatment of Tuberculosis in Lancashire, England

By G. LISSANT COX

(Abstracted from the *Bulletin de l'Union Internationale Contre la Tuberculose*, Vol. XIV, January 1939, p. 50)

THE tuberculosis scheme of the Lancashire County Council was initiated under the National Insurance Act of 1911 and controlled by the county tuberculosis department, inaugurated in 1914. The scheme covers an area of 1,038,130 acres containing a population of 1,859,200.

For dispensary purposes the administrative county is divided into five large areas each with a consultant tuberculosis officer, a small sanatorium-hospital containing up to 56 beds, three small areas each with a tuberculosis officer and a bigger institution (containing up to 226 beds). Each of the eight areas is operated as a unit by a team of whole-time doctors. A special feature of fundamental importance in the scheme is that the dispensary work is combined with the hospital or sanatorium work.

A staff of 33 whole-time tuberculosis health visitors, who are trained nurses and who have certificates of sanitation or health visiting, are responsible for home visiting and for assisting dispensary work in connection with diagnosis, supervision, x-ray examination, and special treatment. These health visitors are to work in close co-operation with the local health department and social service organizations. They are specially trained to write out a report on the environmental conditions of every new case.

Adequate clerical assistance has always been provided in each dispensary.

A high grade of co-operation between the tuberculosis officers and the general practitioners and medical officers of health is maintained and to this co-operation the Lancashire scheme owes much of its success. It is reported that in 1937, 92 per cent of new cases were sent *before notification* to the tuberculosis officers for an opinion as to diagnosis and treatment.

Special endeavour is made to isolate infective cases in a separate bedroom or at least a separate bed by providing bedsteads and mattresses on loan from the dispensary to poor patients, or by assisting them from care funds to purchase the necessary bed clothes. By this means, at the end of 1937, 97.9 per cent adult infectious pulmonary tuberculosis cases had a separate bed. Moreover, under the Housing Act of 1935, the local authorities are to re-house families who are reported by the dispensary staff to occupy over-crowded houses. Thus, every effort is made to improve the housing conditions of the patients.

Regarding institutional treatment, no charge is made by the Lancashire County Council to patients undergoing the treatment. Accommodation is provided for all types of tuberculosis case and there are also facilities for patients to enter village settlements for treatment and occupational training. For pulmonary cases there are 705 beds representing one bed for every 2,637 of the population or 82 beds per 100 deaths from pulmonary tuberculosis. For non-pulmonary cases there are 276 beds, i.e., one bed per 6,736 of the population, or 143 beds per 100 deaths from non-pulmonary tuberculosis.

The county council recognizes the place of after-care in their tuberculosis scheme, encourages the formation of care committees (there are 14 voluntary care committees), and gives liberal financial support to these committees.

There is a central office which plays the major part in the administration of the tuberculosis scheme and acts as link between the dispensaries and the institutions.

The cost of the scheme for the year ended 31st March, 1937, was £195,075, i.e., £105 per 1,000 of the population, or £18,614 per 100 deaths from tuberculosis.

Results.—In 23 years from 1914 to 1937 the tuberculosis death rate in the administrative county has declined 52 per cent and the case rate 49 per cent.

The author believes that such success as achieved in Lancashire is the result of the policy of combining prevention with treatment and hence the tuberculosis scheme has been built upon the foundation of—find, isolate, educate and treat the adult positive cases.

S. R. G.

Tuberculosis in Infants

By DOROTHY PRICE

(Abstracted from the *British Medical Journal*, Vol. I, 5th February, 1938, p. 275)

SEVENTY-EIGHT cases of infant tuberculosis were investigated. All the patients were below one year old and were admitted in St. Ultana Hospital, Dublin, during the last four years.

Of these infants 60 (= 77 per cent) died, and only 18 were cured. Amongst those who died 22 developed caseous pneumonia from flaring up of the primary focus. Deaths occurred within two to three months. Seventeen developed meningitis—amongst these only 14 showed the presence of a primary focus in the lungs. Two developed abdominal tuberculosis—in one of them only the presence of lung tuberculosis could be detected. One had a primary focus in the liver and may be accepted as a case of congenital tuberculosis.

In the cured group of 18, lung lesions were most predominant though the disease was not so widespread. The diagnosis was made from the history of contact, positive tuberculin reaction and x-ray picture. Generally the tuberculin tests were made by rubbing in Hamburger ointment. When this method proved negative Mantoux tests were done with 0.1 c.cm. of 1 in 100 solution. Tuberculin test showed positive reaction after about six weeks from the first infection.

The most dangerous forms of tuberculosis in these infants were miliary and meningeal. The treatment consisted in quick separation from the source of infection, generally the mother, complete rest in bed until all signs of toxæmia had vanished and x-ray picture showed healing changes, diet rich in calcium and vitamins. It took 6 months to two years for healing, and the sedimentation test gave good indication as to the progress or regress of the disease. All kinds of stimulation, such as exposure to sun's rays, movement, etc., must be avoided.

Healing took place mostly by fibrosis and not by calcification. When the healing was complete even the fibrous tissue could not be well seen in the x-ray pictures.

Primary Tuberculosis of the Lungs in Children

By A. MARGARET C. MACPHERSON

(Abstracted from the *British Journal of Tuberculosis*, Vol. XXXIII, April 1939, p. 79)

WITH the purpose of describing the course of primary tuberculous infection of the lungs in children, the author made a study of 850 tuberculous children under observation for eight years at a children's contact investigation department at the Brompton Hospital. The diagnosis of tuberculosis was based on the deposition of calcium in the lung lesion, and/or in the corresponding hilar glands, the positive tuberculin test and the presence of tubercle bacilli in the gastric contents, or material removed through the bronchoscope. None of the children had a positive sputum. The course of the primary lesion was followed by periodic radiological examinations. From a comparison with the work of Blacklock and Burke, the author tried to explain the x-ray appearances in the light of the pathological changes in the lesions. For the purpose of description the primary lesions were grouped as (1) uncomplicated—(a) pulmonary lesion predominating, (b) glandular lesion predominating, and (2) complicated—resulting from (a) hilum lymphadenitis, e.g., pulmonary collapse, bronchogenic spread

of infection and hæmatogenous spread, and (b) from pleural involvement. The glandular enlargement is more extensive in infants and younger children than the corresponding lung lesion. In fact, the extensive glandular involvement usually accompanies a small lesion. Healing in the glands is slower than in the lung focus. From a consideration of clinical and x-ray findings, it has been shown that the primary lesion of the lung in childhood usually takes place without giving rise to any symptoms or signs, and the lesion produced passes from the initial pneumonic stage, through the healing process of resolution and organization or caseation and fibrosis to the final healed or calcified stage, without showing any evidence of its existence, except in the x-ray films. It is the complications occurring during the course of the disease which give rise to signs and symptoms. The process of healing usually occupies more than one year and during this time the focus is always a potential source of dissemination of the disease. The gross hilar adenitis is still more important in this respect as this condition may give rise to acute miliary tuberculosis. To increase the rate of the healing process improved nourishment and increased sunlight have been suggested. The ultimate fate of the calcified focus and its relationship to tuberculous lesions developing in adult life are unknown. Follow up of families of tuberculous patients throughout childhood and adolescence to early adult life may throw more light on these problems.

S. R. G.

The Social Aspects of Tuberculosis

By KARL TISCHEL

(Abstracted from the *Bulletin de l'Union Internationale Contre la Tuberculose*, Vol. XVI, January 1939, p. 6)

TUBERCULOSIS is called a social disease because it is more prevalent with adverse living conditions, occurs frequently during the most productive years of life, and has a tendency to lower rapidly the economic level of the patient and his family. For obvious reasons, tuberculosis is not only a medical but also an economic problem of the greatest magnitude. Since Koch's discovery of the tubercle bacillus, it has been shown that in tuberculosis both the soil and the seed are equally important. The incidence of tuberculosis depends on both environment and exposure. As to the influence of environment, the author quoted the fact that during the three decades since 1900 the living conditions in the United States had been extremely favourable, and, coincident with this remarkable improvement in general health, there had taken place a sharp and accelerated decline in the tuberculosis death rate from 202 in 1900 to 76 in 1929 per 100,000 of the population. During the following eight depression years, in spite of the same active anti-tuberculosis campaign, the same care, and the same clinics and hospital facilities for the tuberculous and their contacts, there had been a small but significant rise in the death rate. Thus, the pendulum of tuberculosis mortality swings with the change in the environment in spite of effective measures of prevention. This conclusion has been amply justified by observations made all over the world during and after the War between 1914 and 1922. The gradual and remarkable decline in tuberculosis death rate in European countries since 1885 was suddenly set back and actually turned the other way by the changed environments of war and its after effects, the loss in the best stock of the population and the survival of the unfit and the weak, the sudden increase in industrialization, the lack of food and other necessities of life, the shortage of housing accommodation, the increased hardship and over-work, the increasing unemployment and economic depression. Environment is, therefore, the determining epidemiological factor in tuberculosis, whereas the prevention of infection, though necessary and desirable, plays a secondary part.

To emphasize the overwhelming importance of environment in tuberculosis the author made a comparison between war and depression. There is an essential difference in the action of forces at play in both situations. During war a great number of adverse circumstances results in a marked increase in the deaths from tuberculosis. During depression there is lack of nutrition, but at the same time, because of the drop in demand and limited production in many industries, there is great reduction in working hours. Therefore, during depression as far as tuberculosis is concerned, the deleterious effect of deficient nutrition is counter-balanced by the protective influence of compulsory rest and avoidance of fatigue. The cycles of depression are again invariably followed by periods of prosperity accompanied by booms in good health.

The term depression is freely applied to cycles of lessened business activity and the diagnosis of the term is made from a variety of symptoms according to the view-point of the observer. But for a social worker the vital statistics are the barometer whose readings only are dependable. The author then quoted exhaustive data from various health surveys and bulletins to show the well-being and health of the American people. In 1937, the bad effects of poor nutrition, inadequate housing and the sense of insecurity were more serious and more widespread in America than in 1932. The diets of low-income families are sadly deficient in milk and other nutritional substances and their energy values are much below the minimum caloric requirements. The incidence of disability due to illness and the annual loss of working days is highest in low-income and relief families. Tuberculosis (all forms) now ranks seventh among the leading causes of death in that country and occupies the eighth place in the chart of disabling chronic illness. It is concluded from all data that the vitality of the American people is impaired, particularly in the low-income classes. People are part of the nation's resources only if they are physically fit, they become a liability when they are incapacitated by illness and want of nourishment. Hence, it is the duty of every government to safeguard all resources of the nation against wastage, including the health of the population. The improvement in housing conditions, the powerful environmental factor in the maintenance of health and prevention of tuberculosis, is to be welcomed. Housing standards in the United States are much lower than in other industrialized countries, such as Great Britain and Germany. The author welcomes the new Federal Housing Programme and recommends that any improvement in this direction must be accompanied by a reduction in rent, the crucial point in the vexing housing problem. The slum clearance by 'model' house building has not been entirely successful elsewhere, as the increased rents in the new buildings tell upon the tenants' already minimal allowances for food, and the resultant nutritional impairment weakens their defences against disease and death. Slums should disappear from any civilized country, but no health scheme can be fully successful unless a minimum existence besides decent housing is provided for all.

The physical fitness of the population depends to a great extent on economic conditions and the impairment of health causes losses to the wealth of the nation. This is particularly true with regard to such a disabling disease as tuberculosis, the prevention of which is not merely a public health problem but also a powerful social and economic one. The measures of control of tuberculosis which had been successful under normal conditions, and which may even forecast further promises in the future, will be proved inadequate under abnormal economic conditions. The eradication of this disease with so many ramifications can only be dreamed of with economic equality which may never come true. So all efforts of control should be reinforced and funds must be found to continue organized anti-tuberculosis work without any letting up. It would be a short-sighted policy to curtail preventive health measures for the sake of economy. Tuberculosis is intimately bound up with universal economic factors. The tuberculosis problem with its wide ramifications

is closely linked up with and cannot be separated from other momentous issues of the day. No definite prophecy as to the future of tuberculosis can be made at the present moment of world-wide turmoil and

unrest. The final conquest of tuberculosis, therefore, depends on the restoration of normal conditions and the survival of civilization.

PULMONARY TUBERCULOSIS: PATHOLOGY, DIAGNOSIS, MANAGEMENT AND PREVENTION.—By G. G. Kayne, M.D., M.R.C.P., D.P.H., W. Pagol, M.D., and L. O'Shaughnessy, M.D., F.R.C.S. 1939. Oxford University Press, London and New York. Pp. xvi plus 565. Illustrated. Price, 42s. Obtainable from Oxford University Press, Bombay and Calcutta

The number of the medical books that are published each year is terrifying; even books in a limited field, such as tuberculosis, must run into three figures each year (Lewis's catalogue includes only about two hundred books on this subject, but they have been carefully selected). In these circumstances, one would scarcely expect to find a 'long-felt want'; yet this book does seem to have shown that a 'want' did actually exist.

It is a book written by a physician, who also has a sanitarian's outlook, a pathologist, and a surgeon: each has been responsible for certain sections of the book, but, as each writer has revised the sections of the other two, there are no sharp lines of demarcation and the book forms a homogeneous whole.

It is generally acknowledged that one of the best ways to acquire a sound knowledge on any subject is to write a book about it; a better way is perhaps to collaborate in writing a book, for the writing of this book must have been a liberal education to each of its three authors. By the time the various sections of this book reached their final draft this education had been completed, to the great advantage of the book and its readers.

The first section, nearly a third of the book, is on pathology. In no other disease is a thorough knowledge of the pathology more necessary to a proper understanding of its clinical aspects. This section includes discussions on the organism itself, the tissue response to infection, allergy, immunity, and natural resistance, and the evolution of the disease in man. We do not know of any other book in which this difficult subject has been so clearly treated.

The next part is on diagnosis, history taking, symptoms, signs, bacteriological investigations, radiological examination, tuberculin testing, and serology and hæmatology. Radiological examination is given 44 pages out of a total of 548; this comparatively small proportion should be noted, as some phthisiologists attach undue importance to a skiagram, and many radiologists appear to consider that the sciences of radiology and phthisiology are identical. Here radiology is put in its right place, which is of course a very important one, but its limitations are defined. In the summary of this section one is a little alarmed to read that 'a complete radiological examination of the chest of a patient may include all of the following: screening in various positions; postero-anterior photographs of various densities in the erect and supine positions and in vertical shift; lateral and oblique photographs and photographs in the lordotic position; double exposure with a Potter-Bucky grid; tomography; bronchography; and kymography'. But we entirely agree that 'single photographs cannot be relied upon in deciding whether a tuberculous lesion is active'.

In the chapter on bacteriology emphasis is laid on the value of bacteriological examination of the gastric contents, even in adults; it has for some time been recognized as the best method of confirming a diagnosis in children.

The Mantoux test is naturally given preference to other tuberculin tests, and the use of P.P.D. is strongly advocated.

Part III is a comparatively short one, on prognosis.

Part IV is on the management of pulmonary tuberculosis, on the principles of treatment, criteria of progress, the completion of treatment, and modes of treatment. The modern tendency is again well reflected in the apportionment of space; out of 161 pages on the modes of treatment, 144 are devoted to collapse therapy. The surgical procedures of the various methods are described in detail. There is an appendix to this part in which the course of the disease and the different treatments given in 20 cases are shown on charts.

The last part is a short but very important one on epidemiology and prevention.

This is a book that should be very widely read in India where tuberculosis is now being tackled seriously. We know of no other book that covers the whole subject so completely. It is an excellent book and one that we can very strongly recommend to the sanitarian, the practitioner, the tuberculosis specialist and also to the surgeon.

TROPICAL MEDICINE.—By Sir Leonard Rogers, K.C.S.I., C.I.E., LL.D., M.D., B.S., F.R.C.P., F.R.C.S., F.R.S., and Sir John W. D. Megaw, K.C.I.E., B.A., M.B. (Hon.), D.Sc. (Queen's University). Third Edition. 1939. J. and A. Churchill, Limited, London. Pp. xli plus 544, with 2 coloured plates and 87 text-figures. Price, 16s.

It was once said that one only had to settle in a tropical country with a microscope and a bottle of Leishman's stain to make a startling discovery each day. That time has passed; the centre of focus in tropical medicine is no longer on parasitology; it is daily moving towards biochemistry. This excellent practical book on tropical medicine to some extent owes its origin to a desire on the part of its authors to protest against the purely parasitological outlook that was the rule during the first post-war decade, and to keep the attention of the student and physician closer to the bedside from whence he can view the relative importance of the various auxiliary sciences without prejudice.

The general trend of opinion during the last ten years has fully justified this point of view, or, as these two authors can undoubtedly be considered leaders of thought in tropical medicine, perhaps one should say, their teaching has borne fruit.

The rapid exhaustion of the second edition has given the writers of this book an opportunity to revise it and bring it up to date. One associates with the word 'tropical' a rapid growth and this is one of the outstanding characteristics of tropical medicine, so that in a period of four years much will happen and considerable revision will be necessary after such an interval. This revision has been carried out in every section and some of the chapters have been almost completely rewritten.

The temptation to expand the book has been firmly resisted, so that it still remains a 'short' tropical medicine, without showing any traces of being a synopsis, or cram book. We agree with the authors that references would be entirely out of place in a book of this kind; in justification for this attitude they mention that the literature on typhus fevers alone now runs to a thousand references.

The most extensive revision has been carried out in the chapters on typhus, yellow fever, cholera and

dietary diseases. The recent studies on tropical typhus in India have been summarized well. The pioneer work of the writer of this section was largely responsible for focussing attention on this disease, which was not recognized before his day. The new confusing element, jungle yellow fever, which is not transmitted by *aedes* and does not depend on man as a carrier, is reported; as the writer says, this does not change our ideas of the epidemiology and prevention of the *aedes*-borne urban yellow fever, but it does appear to postpone almost indefinitely the day when this disease will be banished from the world.

In the chapter on cholera, which is one of the best in the book, all the recent work on the bacteriology of this disease has been included and a fair appraisal of bacteriophage, prophylactically and as a curative agent, is given. In the section on diet in health and disease, there is a new and up-to-date table showing the principal vitamins, their properties and the diseases associated with their absence from, or deficiency in the diet, and all recent work, such as that on nicotinic acid in pellagra, is incorporated.

There is no increase in the size of the volume but the publishers have very cleverly increased the amount of printed matter on each page, without altering the type or decreasing the readability. From an æsthetic point of view it is still a pleasant page with a sufficiently wide margin.

This third edition can scarcely fail to enhance the already established popularity of this book.

L. E. N.

MODERN TREATMENT IN GENERAL PRACTICE: YEAR BOOK 1939—A YEAR BOOK OF DIAGNOSIS AND TREATMENT FOR THE GENERAL PRACTITIONER.—Edited by C. P. G. Wakeley, D.Sc., F.R.C.S., F.R.S.E., F.A.C.S., F.R.A.C.S. (Hon.). Butterworth and Company (India), Limited (Incorporated in India), Calcutta and Bombay. Pp. xii plus 365. Illustrated. Price, Rs. 7

Six years ago, the *Medical Press and Circular* started a series of articles on modern treatment in general practice, and at the end of the year they published these in book form. The next year these useful articles were continued and again issued in book form, as *Modern Treatment in General Practice*, Vol. II. In 1937, volume III appeared. In 1938 there was a slight change in the title, the volume number was dropped and the year substituted, so that the volume appeared as *Modern Treatment in General Practice*, 1938. This year there is a further modification of the title and the series of articles that were published in our invaluable contemporary during 1938 are reprinted in book form as the *Modern Treatment Year Book*. Thus another 'annual' has been born.

In this volume there are 36 articles on modern treatment by well-known British physicians and surgeons; these include Sir Humphry Rolleston, Sir Walter Langdon-Brown, Dr. Letheby Tidy, Mr. Cecil Wakeley, and Mr. Alec Bourn. There are also a dozen articles from that useful series 'Pitfalls in Diagnosis'.

There are two articles in the series which will be more useful to readers in this country than to those in Great Britain, namely, on malaria and blackwater fever, respectively. Dr. Murgatroyd has given a good account of the treatment of malaria in different circumstances. The same writer contributed the chapter on blackwater fever which is a sound and practical guide to the treatment of this dangerous disease; he is guarded in his recommendation of blood transfusion and suggests that it may be resorted to as a life-saving measure in cases of extreme anaemia. Two points to be remembered are that in no disease is blood regeneration more rapid than in blackwater fever and that once the organism has adjusted itself, and this must be a matter of hours at the most, a patient can carry on with 10 per cent of his normal allowance

of hæmoglobin, so that, unless it can be claimed that blood transfusion decreases the danger of further hæmolysis, which seems unlikely, there is, in the reviewer's opinion, little room for it in the treatment of this disease.

The main point about this series is that no attempt is made to cover the whole range of medical and surgical treatment each year, but as far as possible new subjects are chosen, so that, if one adds a volume every year, the whole collection will form a kind of encyclopædia of treatment which any practitioner will find very valuable for reference.

A SYNOPSIS OF HYGIENE.—By Sir W. Wilson Jameson, M.A., M.D. (Aberd.), F.R.C.P., D.P.H., of the Middle Temple, Barrister-at-Law, and G. S. Parkinson, D.S.O., M.R.C.S., L.R.C.P., D.P.H., Lieut.-Col., R.A.M.C. (Retd.). With a section on Personal Hygiene by G. P. Crowden, D.Sc., M.R.C.S., M.R.C.P. Sixth Edition. 1939. J. and A. Churchill, Limited, London. Pp. viii plus 687, with 16 illustrations. Price, 21s.

This book has almost become a 'classic', although its original authors have revised the present edition; it is therefore scarcely necessary to do more than announce that a new and completely up-to-date edition has been published.

'Hygiene' is a wide field and a single volume on the subject must necessarily be a synopsis. In this book, however, the subject is presented in very readable form, and is not simply a series of tabulated statements. It is a book that will be invaluable to the D.P.H. student, as well as to the undergraduate student who is taking a degree for which some general knowledge of hygiene is essential. The book will also prove very useful to any practitioner, as there are many matters connected with even personal hygiene which he will find dealt with far more clearly and completely than in any book on general medicine.

Admittedly, the book is written primarily for the student and practitioner in Great Britain, but all the principles and most of the details are applicable to conditions in India.

For many years the student in this country will have to rely on 'foreign' teaching on this subject, not because good books cannot be, and have not been, written, but because the data on which the teaching is based are not yet available in this sanitariously-backward country.

It is a book we can strongly recommend to the student and teacher in India.

ESSENTIALS OF FEVERS.—By G. E. Breen, M.D., Ch.B. (N. U. I. Dub.), D.P.H., D.O.M.S. (R.C.P. Lond., R.C.S.Eng.). 1939. E. and S. Livingstone, Edinburgh. Pp. xii plus 274. Illustrated. Price, 7s. 6d. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 5

In this small volume the author has dealt with the 'essentials' of these acute infectious diseases commonly known as 'fevers'. Cases of fever form a large proportion of the patients that a general practitioner has to attend to in his day-to-day practice and the importance of a practical knowledge of the subject of fevers can hardly be over-emphasized.

The author has described the general features, the sources, the results of, and spread and control of, the infections in the first three chapters. These chapters contain a vast amount of information. The section on examination of the fever cases and the general measures of treatment contains practical details that will be found useful by students and practitioners alike. The different diseases have been dealt with satisfactorily and there are no omissions of vital facts.

The book will prove useful to medical students and young practitioners.

P. C. S. G.

YAKSHMA O TAHAR PRATIKAR—(TUBERCULOSIS AND ITS TREATMENT)—IN BENGALI.—By Dr. Bidhu Bhusan Pal, Teacher of Dacca Medical School (Retd.). First Edition. B. S. 1346. Published by Purnendu Bhusan Pal, 39/5/1A, Gopal Nagar Road, Allpore P. O., Calcutta. Pp. 96. Price, Re. 1. Available from Messrs. M. C. Sarkar and Sons, Limited, Collogeo Squaro, Calcutta

IN view of the fact that about a hundred thousand people die of tuberculosis every year in Bengal, and many more are incapacitated by it, any attempt at mass education in the various manifestations of the disease and its prevention is certainly praiseworthy. Not many books have appeared in Bengali on the subject, so there is room for many more.

Most of the essential facts about tuberculosis have been condensed in ninety-six pages in simple Bengali which even a schoolboy should have no difficulty in understanding.

The book is admirably suited not only for the laity but also for the Bengali village practitioner.

A. K. M.

CANCER: CAUSATION, PREVENTION AND TREATMENT.—By A. E. Blackburn, M.D. 1939. H. K. Lewis and Company, Limited, London. Pp. viii plus 111 with 14 illustrations. Price, 6s.

THIS book is an enthusiastic presentation of the author's theory that cancer is caused by excessive ingestion of animal fats. He accepts Warburg's dictum 'If the respiration of a growing cell is disturbed as a rule the cell dies. If it does not die a tumour cell results' and the observation made by Watermann regarding the effect of diet on mice developing tar cancer. The latter investigator found that sugar had a slightly unfavourable effect, that protein amino-acids had no action, and that animal fats had a very unfavourable influence.

Dr. Blackburn observes that the possession of an excess of carbon atoms is an essential feature of all proved carcinogenic substances—soot, paraffin, tar, dibenzanthracene, œstrone, testosterone, etc. He includes in this series animal fats of high molecular weight, like the fat of the ox, the sheep and the goat. He states that the free carbon atom arrests the oxidation of the cell and a state of continued sub-oxidation results in malignancy. Externally the free carbon atom impinges on the body as soot, tar, tobacco fumes, etc., and internally as ingested animal fat of high molecular weight. The rôle of fat native to the human body when forced by pressure or injury into ducts and acini, in producing carcinoma of the breast or of the fat of the smegma preputii in producing cancer of the penis and cervix and the applications of this theory of suboxidation to genesis of cancer in other organs of the body, can be appreciated best only by reading this stimulating book.

Arguments in favour of the theory based on a study of the diets of primitive and civilized races and even on historical injunctions of the Old Testament have been clearly and cogently presented. Modern civilization as affecting the problems of diet, dress and parenthood is criticized by Dr. Blackburn at different places in the book.

The age of circumcision amongst Muslims is stated by the author to be about 14 years. This rite is performed by the millions of Muslims inhabiting India before the age of 5, and frequently soon after birth.

The higher incidence of cancer amongst Hindu women as compared with Muslim, in India, is ascribed by Nath and Grewal to the custom of early marriage amongst the Hindus and the trauma of frequent confinements under unhygienic conditions leading to chronic cervical sepsis. Dr. Blackburn quotes the same data in support of conjugal origin of cancer of cervix uteri suggesting a carcinogenic rôle to the fatty preputial secretion.

The subject-matter of the book is well arranged and well presented. The expression of views in places is

a little too emphatic, but the advancement of a new theory always demands a certain amount of dogmatism.

V. N.

AIDS TO DERMATOLOGY AND VENEREAL DISEASE.—By R. M. B. Maokonna, M.A., M.D., B.Ch. (Camb.), M.R.C.P. (Lond.). Second Edition. 1939. Baillière, Tindall and Cox, London. Pp. vii plus 284. Illustrated. Price, 4s. 6d.

THIS is a summary of diseases of the skin and venereal diseases which, like the other volumes of this series by the same publishing house, can be classed as a useful book for rapid revision of the subject by students just before an examination to remind them of the main points, but in the reviewer's opinion it should not be used for any other purpose as it does not take the place of a larger book. One criticism we have to offer is the inclusion of yaws among the venereal diseases, and the reasons given by the author for this unusual step are not convincing.

GENETICS AND THE CLINICIAN.—By Lindsay Ride, M.A., M.B., Ch.B. (Oxon.), M.R.C.S. (Eng.), L.R.C.P. (Lond.). 1938. John Wright and Sons Limited, Bristol. Pp. xiii plus 146. Illustrated. Price, 10s. 6d.

THERE is a need for a book like this amongst medical men. An attempt has been made to present the old and the new order of things in heredity in a readable form. The preservation of the ancient usage for describing contrasting characters, unfortunately, is still in the way. If the capital T represents the dominant character tall, why should the small t represent the recessive character dwarf? Small d is the appropriate symbol. The capital W is utterly unsuited to represent the dominant red eye of the female fruit-fly (*Drosophila melanogaster*) for the purpose of teaching genetics to the clinician who is essentially a busy man. Decoding and following the new combinations at the same time is irksome, to say the least. Even eminent biologists of a bygone generation like the late Professor J. A. Thomson agreed to discard the usage in the interest of lucidity.

The stages in the splitting of the chromosomes have been kept well under control, considering that some recent workers in cytology claim to see more than two strings of genes in a chromosome always. Chromosomal basis of the naturally and perpetually occurring variation in living things is explained in a nutshell. Cytoplasmic inheritance is not lost sight of.

Introduction to genetical ratios in human data is excellent. Anthropological physiology is thought stimulating. Inheritance of serological characters is very well treated; lawyers with a biological inclination will find it useful in dealing with evidence on blood groups.

The binding, the paper and the printing are good. The size of the page could perhaps have been smaller. The price is not unreasonable.

S. D. S. G.

GYNÆCOLOGY.—By Herbert H. Schlink, M.B., Ch.M. (Sydney), F.R.A.C.S. 1939. Angus and Robertson Limited, Sydney and London. Pp. xv plus 557. Illustrated. Price, 32s. 6d.

A TEXTBOOK written primarily for students should possess certain features—clearness of expression, interest, good print and illustrations, compactness without sacrificing essentials, and cheapness.

Mr. H. H. Schlink has written a book which has these characteristics with the exception of the last. (The price is high for a student's pocket.)

The author writes with the obvious sincerity and conviction of much experience, and with the desire to give sound instruction to students.

One or two points of his advice might not coincide with the teaching in other schools, in respect to endocrine therapy, the choice of operation for retroversion, and the 'purgation' treatment of peritonitic ileus.

The pathology of some of the ovarian cysts is a little confusing. The terms 'blood cysts', 'tarry cysts' and 'chocolate cysts' are not happy, especially as in one place 'Chocolate cysts' are included under the heading 'tarry cysts' whilst in another they appear under endometriomata, each in the classified list of tumours being made a separate entity. The reader is a little bewildered in this section of the book.

These points are raised with no intention of detracting from the general excellence of the book. Special interest is aroused by the chapter on malignancy, and the photomicrographs are especially helpful and clear. Chapters on examination of the patient, operative gynaecology, and post-operative complications are included.

This book is recommended with confidence to all senior students, and to general practitioners.

K. S. F.

CATALOGUE OF LEWIS'S MEDICAL AND SCIENTIFIC LENDING LIBRARY. PART II. CLASSIFIED INDEX OF SUBJECTS, WITH NAMES OF AUTHORS WHO HAVE WRITTEN UPON THEM. 1939. H. K. Lewis and Company, Limited, London. Pp. 156. Price, Complete 16s. (Subscribers 8s.)

PART I of this useful catalogue was reviewed in the March number. This obvious and necessary corollary has been completed with the same care and thoroughness, and it shows how completely 'Lewis's' covers the whole range of medical subjects.

We mentioned before that the catalogue will form a useful book of reference for any medical library, and for the subscriber to this famous library it will of course be invaluable.

Abstracts from Report

KING EDWARD VII SANATORIUM, BHOWALI, U. P. ANNUAL REPORT FOR 1938

At the request of the committee, the Inspector-General of Civil Hospitals paid a visit to the sanatorium in January to report if it was desirable to keep the institution open during the winter months also. On his recommendation the committee decided that it should remain open throughout the year in future. The result was that patients joined much earlier at the commencement of the year than in the past and the accommodation was occupied for a longer period. The temporary closure of the sanatorium during the winter season not only caused hardship to those patients who wanted to stay during this period but it also affected the continuity of treatment among others who were showing satisfactory response to treatment. His Excellency Sir Maurice Hallett during his visit to the sanatorium on 9th September, 1938, remarked, 'I trust more will remain in future, for I feel sure that many patients would benefit by staying in the healthy surroundings and invigorating atmosphere of Bhowali instead of returning to possible unhealthy residence in the plains'.

Thirty-two patients remained in the sanatorium on 1st January, 1938, from the previous year, and 242 patients were admitted and 203 patients discharged during the year under report. The daily average number of patients treated was 99.40. The largest number of patients was 136, during the months of May and August, and the lowest number on any single day was 29 in the month of January.

The following improvements are worth mentioning:—
Improvements in the 'D' class ward.—The roof has been extended and the verandah closed in by doors and windows, due regard being paid to ventilation. Wooden partitions have been erected up to a certain height dividing the ward into ten cubicles, two patients

occupying each cubicle. This has given a certain amount of privacy. These changes have undoubtedly added to the comforts of the patients of the 'D' class.

A verandah and two rooms have been added to the south side of the recreation hall.

Additions and alterations in the administrative building.—The staff increased during the last two years and office accommodation was required for the newly appointed junior clerk and for the overseer. It was also necessary to shift the ultra-violet-ray lamp from the surgical annexe to the x-ray department, which is the proper place for it.

Post-graduate training.—Two doctors, one of them from Jaipur State, were sent for training for three months.

Since the post-graduate training received in the Bhowali Sanatorium is recognized by the University of Wales for its Tuberculous Diseases Diploma examination, the committee decided to give necessary facilities for training on payment of Rs. 150 as fees for a renewable period of three months and the Superintendent was also authorized to charge Rs. 75 for accommodation for the same period if such accommodation was available in the sanatorium.

Social activities.—The importance of amusement and recreation in the treatment of pulmonary tuberculosis is universally recognized. Anything that can relieve the monotony of long stay in the sanatorium and divert the patients' minds from their disease without detriment to their health is considered as a part of sanatorium treatment. With this object in view a number of social activities and recreative diversions were arranged from time to time.

Library.—A number of books and magazines were presented by the Red Cross Society and other friends for which the sanatorium is very grateful. The library possesses a number of books in Hindi, Urdu, English and Bengali, and they are freely used by the patients.

The sanatorium continued to receive gift copies of the following and is grateful to the editors for them:—

The *Statesman*, *Pioneer*, *Illustrated Weekly of India* and the illustrated weekly edition of the *Leader*.

The *Hindustan Times* and *National Herald* were added as gifts to the above list during the year under report and our thanks are due to the editors of the two dailies.

Horlicks Ltd. continued to supply free copies of the *Sphere*, *Strand* and *Til-bits* and we gratefully appreciate their generous gift.

The sanatorium altogether gets seven dailies, one bi-weekly, three weeklies and eight monthlies for the benefit of the patients.

Donations.—Sir J. P. Srivastava gave a donation for the construction of a block of six rooms for use of the female patients to commemorate the marriage of his first daughter. The cost of the block came to Rs. 5,700 and with the approval of the donor it has been reserved for female patients of the 'C' class.

At the time of his visit to the sanatorium last year, the Honourable Premier was pleased to announce that the Government would give a suitable donation for providing modern amenities to the patients in the newly constructed recreation hall. A non-recurring grant of Rs. 3,000 was sanctioned by the Government for this purpose.

Mr. Shiv Nath Singh gave a donation of Rs. 300 to commemorate the memory of his late wife who was a patient in the sanatorium in 1934 and 1935.

Inspection.—The sanatorium was officially inspected by Colonel J. A. S. Phillips, C.I.E., V.H.S., D.P.H., I.M.S., Inspector-General of Civil Hospitals, on 3rd October, 1938. He was pleased to observe that the whole sanatorium was 'spotlessly clean and the patients comfortable and well looked after', and he congratulated Dr. Shrikhande and the Staff on a 'well-run and well-maintained institution'.

The financial condition of the sanatorium remained satisfactory.

The most pressing need at the present moment is electrification.

An Appeal.—The moving appeal issued by Her Excellency the Marchioness of the Linlithgow on

behalf of the King-Emperor's Anti-Tuberculosis Fund in order to combat the growing scourge of tuberculosis in India has aroused considerable interest. Whatever measures are adopted in connection with the fund, there can be no doubt that the King Edward VII Sanatorium at Bhowali which is the only public institution of its kind in the province will continue to serve its useful purpose. I therefore approach the public for giving increasing support to the institution. Public donations apart from those at the time of its establishment have been very rare and any help, in cash or kind, would be gratefully appreciated.

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL T. C. BOYN has been appointed Inspector-General of Civil Hospitals, U. P., from 10th June, 1939.

Lieutenant-Colonel A. S. Garewal, on return from leave, is re-posted as Superintendent, Central Jail, Jubbulpore, from 5th July, 1939.

The services of Lieutenant-Colonel B. P. Baliga, Superintendent, Dum Dum Central Jail, are replaced at the disposal of the Government of India, for employment in the Military Department, with effect from the date of expiry of the leave granted to him.

Major B. J. Griffiths has taken over charge as Civil Surgeon, Lucknow, from 14th June, 1939, afternoon.

Major R. A. Wesson, on return from leave, took over charge as Civil Surgeon, Allahabad, on 26th June, 1939.

Major F. R. W. K. Allen, on return from leave, is re-posted as Civil Surgeon and Superintendent, Robertson Medical School, Nagpur, from 3rd July, 1939.

Major S. Annaswami, Superintendent, Midnapore Central Jail, is appointed to act as Superintendent, Dum Dum Central Jail, with effect from the 20th July, 1939, or any subsequent date on which he actually takes over charge, *vice* Lieutenant-Colonel B. P. Baliga, on leave.

Major A. N. Chopra, Officer in charge, Medical Store Depot, Lahore Cantonment, whose services are placed at the disposal of the Government of the Central Provinces and Berar, with effect from the 11th July, 1939, forenoon, is posted to the Central Jail, Jubbulpore, for training with effect from 17th July, 1939.

The services of Major E. A. R. Ardesir, which were transferred by the Government of India, Defence Department (Army Branch), to the Civil Medical Department of the Government of Bengal, with effect from the 26th November, 1938, are hereby placed at the disposal of the Home (Jail) Department of this Government, with effect from the same date.

Captain G. W. Miller has been transferred as Port Health Officer, Bombay.

Captain T. Sommerville is transferred to the Civil Jail, Port Blair, in addition to his own duties, with effect from the 22nd May, 1939.

Captain T. Sommerville is transferred to the Civil Branch of the Indian Medical Service. He is appointed to the Medical Research Department, on probation for 2 years, with effect from the 30th May, 1939 (afternoon), and is attached to the Pasteur Institute of Southern India, Coonoor.

Captain F. C. Leach, Civil Surgeon and Superintendent, Robertson Medical School, Nagpur, is posted as Civil Surgeon, Saugor, from 10th July, 1939.

Captain J. W. D. Goodall, Civil Surgeon, Midnapore, is appointed to act as Superintendent, Midnapore Central Jail, in addition to his own duties, with effect from the date on which Major S. Annaswami proceeds to take charge of the Dum Dum Central Jail.

LEAVE

Lieutenant-Colonel D. Clyde proceeded on 3 months' leave from 15th June, 1939.

Lieutenant-Colonel B. P. Baliga, Superintendent, Dum Dum Central Jail, is allowed leave on average pay for 4 months, with effect from the 20th July, 1939, or from any subsequent date on which he is relieved.

Lieutenant-Colonel C. J. Lodge Patch, M.C., Medical Superintendent, Punjab Mental Hospital, Lahore, proceeded on leave on half-average pay for 2 months and 28 days, with effect from the 21st July, 1939.

PROMOTION

Lieutenant (on probation) to be Captain (on probation)

W. S. Hacon. Dated the 11th July, 1939.

RESIGNATION

Captain K. I. E. Macleod resigns his commission. Dated the 25th March, 1939.

Notes

CARDIAZOL

CARDIAZOL is a circulatory and respiratory stimulant with a central action, and is rapidly and completely soluble in water and lipoids; hence its surprisingly prompt action. It can be administered *per os*, subcutaneously, intramuscularly and intravenously which multiplicity of forms of application gives it decided advantages over camphor and also over strychnine. It acts directly on the nervous centres and increases their excitability. The excitant effect on the vasomotor and respiratory centres is especially important. That on the vasomotor centre results in an increase of the volume of blood in circulation, due, primarily, to constriction of the vessels in the splanchnic region, followed by improvement of blood pressure and cardiac performance. The excitation of the respiratory centre brings about a deepening and slowing of respiration, with an increase in respiratory volume. These beneficial results are further supported by direct dilatation of the bronchi. The favourable influence of cardiazol on expectoration deserves to be stressed. Its main indications are circulatory disturbances (especially vasomotor debility), collapse, respiratory paralysis, infectious diseases, poisoning, as well as bronchial asthma. In surgical practice cardiazol is highly valued as a means to overcome incidents during anaesthesia, and as a rousing agent.

A NEW SYNTHETIC ESTROGENIC SUBSTANCE

The sex hormones, particularly the female hormones, have now taken a definite place in the armamentarium of the modern physician. By their use in the treatment of disorders of the menopause in women it is possible to soften the blow and render the stormy passage comparatively smooth and uneventful. Their value is not confined to climacteric disorders but makes itself evident in ovarian deficiency and disorders connected with the female generative system in general.

Until the present all substances used in practice have been hormones derived from the human and animal body consequent on the discovery of Ascheim and Zondek (1927) of their presence in the urine of pregnancy. While the isolation of pure crystalline substances from natural sources has simplified the question of standardization, the process of manufacture is attended with considerable difficulty and expense.

The various researches which led to the elucidation of the chemical structure of the hormones Estrone and its related compounds stimulated efforts to

synthesize them and these in turn led to the search for simpler substances possessing oestrogenic activity. The progress of simplification from the complex sterol derivatives via the tetrahydronaphthalenes to the dihydro-diphenyl derivatives was rapid (Dodds and his co-workers) and a notable point in the search has been reached in the discovery that the even simpler stilbene derivatives possess an activity surpassing that of the natural products.

The Crookes Laboratories now offer to the medical profession one of the most active of such products yet discovered, 4,4'-dihydroxy α , β -diethyl stilbene under the name of Neo-Estranol I.

GYNÆCOLOGICAL INDICATIONS

Menopause—natural or artificial following surgical procedures. Hypoplasia of the uterus, amenorrhœa, hypomenorrhœa without hypoplasia, oligomenorrhœa, dysmenorrhœa, pruritus and kraurosis vulvæ, menorrhagia, frigidity, delayed puberty. Gynæcological hæmorrhage, sterility and habitual abortion. Senile vaginitis, toxæmias and vomiting of pregnancy.

A RESPIRATORY AND CIRCULATORY STIMULANT

'NICAMIDE' nicotinic acid diethylamide, a powerful respiratory and circulatory stimulant, is prepared by Burroughs Wellcome and Co., Snow Hill Buildings, London, E.C.1, and is available to the medical profession as a 25 per cent solution for oral administration, in bottles of 15 c.cm. and 100 c.cm. and as Hypoloid Nicamide, a 25 per cent solution for intravenous or intramuscular injection in ampoules of 2 c.cm. and 5 c.cm. Following the administration of Nicamide, depth and frequency of respiration are stimulated, and the force of cardiac contraction is increased. The drug causes a rise in blood-pressure probably brought about by reflex stimulation of the vasomotor centre through the carotid sinus. Nicamide acts effectively either by mouth or by injection; the indications for its use include all conditions associated with shock and depressed circulatory and respiratory states.

AN IDEAL STIMULANT IN METABOLIC DISORDERS

THE stimulating properties of Brand's Essence—due to the high degree of solubility of its natural protein—make it invaluable to the medical man in all cases where the minimum energy can be spared for digestive effort. Brand's Essence liberates and strengthens the gastric juices; assimilation is speedy, most of the free acid being absorbed by the soluble protein which leaves no solid precipitate or irritant.

In stomach disorders, childbirth, pneumonia, and all febrile conditions there is no tonic so readily acceptable by the debilitated digestive organs, or more markedly stimulating in its effect. It can be given at a moment's notice with a teaspoon and, as it does not cause thirst or diarrhœa, can be taken freely without putting any strain on the kidneys. There is practically no chronic condition in which it cannot be prescribed with safety and advantage, for which reason it has enjoyed the confidence of the medical profession for more than 100 years.

M. & B. 693 IN THE TREATMENT OF PNEUMOCOCCAL INFECTIONS (FOURTH EDITION)

THE considerable extension of the use of M. & B. 693 in the treatment of pneumococcal infections has resulted in the appearance of a new edition of the booklet on this product, a copy of which has been sent to us by the manufacturers, Pharmaceutical Specialities (May and Baker) Limited, Dagenham.

Reference is made in the booklet to a new packing in which the drug is now obtainable, a box of

6 ampoules of the sodium salt of M. & B. 693, supplied in India at Rs. 11-13. The manufacturers emphasize that this product is for intravenous or deep intramuscular injection. Details of administration are included in the booklet.

We understand that Messrs. May and Baker (India), Limited, 11, Clive Street, Calcutta, will be glad to send copies of this booklet on request to members of the medical profession.

A PRONTOSIL BOOKLET

It is not necessary to enlarge upon the importance of the contribution which 'Prontosil' has made towards the treatment of disease. Since its introduction in Germany, in 1935, 'Prontosil' has aroused the greatest interest throughout the world. The abundance of publications in the medical literature, however, makes it difficult for doctors to get a clear idea of the most important experimental and clinical facts that are now known about these drugs.

Bayer Remedies Limited has issued a book in which they have attempted to collect and classify these facts, so that information on any particular question can be readily obtained. Only the more important references (about one-fifth of the total available) have been chosen, and these give chapter and verse for all the statements made. The contents are arranged in three main sections—Experimental Findings, Clinical Experience, and Therapeutics—and are, we believe, more in the nature of a well-balanced review of the subject than a collection of summaries of published work.

The medical profession will find this an invaluable book of reference on this important subject.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

CLINICAL AND PROGNOSTIC FACTORS IN TYPHOID IN INDIA

By R. L. HAVILAND MINCHIN, M.D.

CAPTAIN, I.M.S.

*Late Additional Professor of Medicine, Medical College
and Physician, General Hospital, Madras*

IN spite of improvements in sanitation, the treatment of the enteric group of fevers still forms one of the major problems of the medical man in tropical countries, for example, in 1936, the last year for which complete statistics are available, 1,363 cases of enteric fever were treated at the Madras General Hospital.

Medical literature reveals an astounding series of contradictory statements on the subject of enteric in the tropics. Thus, while Manson-Bahr (1935) speaks of 'the well-known immunity of native races', Rogers and Megaw (1935) state that typhoid is very frequent in India, while Lakin (1937) insists that para-typhoid A is pre-eminent.

During 1936-1938, when the 444 cases of typhoid mentioned in this paper were in hospital, only three cases of para-typhoid A and two of B were admitted, and Uttley (1938) reports a similar overwhelming majority of typhoid infections among the enteric cases in Hong-Kong.

For the purpose of this paper, the case reports of all cases of the enteric group of fevers admitted to three comparable units of the Madras General Hospital during the period under investigation were examined. All the cases showing definite bacteriological evidence were included in the examination; by that is meant all cases from which enteric organisms were isolated or those cases showing a Widal agglutination at least 1 in 200 dilution. This may be an insufficiently high concentration for definite diagnosis: though Box (1937) considers that any agglutination over 1 in 50 should be considered positive, and Lewin (1938) states that after examination of over twenty-thousand sera, he considers that, in the uninoculated, such as were these, a 1 in 100 H and 1 in 200 O agglutination are suitable for diagnosis. Taking these figures he has found an error of under 3 per cent. I agree that a certain rise in blood agglutinins can occur in an old typhoid case or previously immunized individual suffering from any fever; but with the possible exception of tropical typhus, a titre as high as 1 in 200 will very rarely be obtained. In favour of this view is the fact that in only 3.6 per cent of the cases examined was there any rise in agglutinins towards other organisms of the enteric group, and where this did occur the titre was never over 1 in 50.

The methods of examination of suspected enteric cases in this hospital should be mentioned. As a routine, all patients with fever are

first examined for malaria and a blood film is taken. If no parasites are discovered the next day, and if the temperature has not returned to normal, blood is taken for culture and Widal. In this way the blood of many patients showing signs and symptoms suggestive of dengue, broncho-pneumonia or malaria is examined, and it will be seen that a large proportion are found to be culturally or serologically typhoid, a fact that has been emphasized by Box (1937). Unfortunately, it has been found impossible to carry out the routine examinations to a titre of over 1 in 200, and where 1 in 200 is shown as the titre of the serum it should be read as 'at least 1 in 200'.

Consideration of treatment.—In the absence of any universally recognized specific treatment, it is not surprising that individual physicians have their own methods which they are convinced produce satisfactory results. In this hospital, opinion ranges between the classical low diets, almost to the administration of the very high calorific diets advocated by Coleman (1917). It was to demonstrate the comparative complication rate and ultimate prognosis with vastly different methods of treatment that this report was produced. A short summary of the routine lines of treatment followed in the three medical units is given below:—

Physician A, for the first ten days of the fever, allows his patients three pints of citrated milk daily with small quantities of bread and butter, and such light foods as ground rice or blanc-mange *congee*. In addition to this, he gives orange juice, cod-liver oil and Marmite soup to prevent the development of vitamin deficiencies. After the tenth day, the solid part of the food is stopped and only the three pints of milk, blanc-mange and the vitamin concentrates continued. Any constipation is treated by glycerine enemata.

Physician B gives a diet nearer the classical starvation type. During the fever only two pints of milk and a little barley water or arrowroot are permitted with orange juice and glucose. Only after the fever has been normal for two days is higher diet permitted. Constipation is not regarded with concern, but if it is persistent it is treated with glycerine enemata, and, if associated with distension, with fractional doses of calomel.

Physician C (R. L. H. M.) attempts to keep all typhoid cases on a diet of at least 2,500 calories consisting of milk products, ground rice, jellies, biscuits, arrowroot, bread, butter, vegetables, etc.

This diet is maintained throughout the fever provided that the patient is willing to eat it, the only reason for stopping it being the development of abdominal distension, diarrhoea, or hæmorrhage. In addition any constipation of over one day is dealt with by the administration of one drachm of castor oil daily, with the object of obtaining at least one soft motion daily. The idea being that a paralysed gut in constant

contact with toxins is far more likely to become distended, to perforate, or bleed than one kept in a state of mild peristalsis by the use of small doses of an aperient. The method is a modification of that introduced by Cree and Carter (1907) and advocated by Colonel S. G. S. Haughton. It need hardly be mentioned that such a line of treatment is looked upon with horror by the bulk of orthodox physicians (Box, 1935).

It should be mentioned that the lines of treatment given above are what are attempted, and are not always obtained, as certain of the patients refuse to take the diets and medicines prescribed.

Results of treatment

These can be seen in table I, which gives the symptoms on admittance, the complications and results in each unit, and in table II which shows the cause of death.

Table I shows that the average length of fever (in recovered cases) was almost the same in each unit (24 days) and the mortality figures (13.7 per cent) show no real difference, the number of 'bowel complications', i.e., tympanites, perforation, hæmorrhage and diarrhœa being for Physician A (low diet) 23 per cent, Physician B (lower diet) 27 per cent, and Physician C (higher diets and open bowel) 21 per cent. Examination of table II which gives the causes of death in each unit shows that in unit 1 bowel complications produced four deaths, in unit 2 seven and unit 3 three. From these figures it might be argued that the method of open bowel therapy reduces the death rate from the bowel complications; but the total death rate is approximately the same in each unit. Nevertheless, the figures do show that the administration of purgatives in moderate doses produces no adverse effect, and I am convinced that it gives the patient far more relief than the usual method of only emptying the lower bowel by means of enemata.

Symptoms on admittance—table I

Unfortunately patients are liable to be admitted at any stage of the disease and consequently these figures have only a limited value, and the hope that a study of the symptoms on admittance might give a clue as to which cases were likely to prove serious was disappointed; however, the table does bring to light certain significant points. The first is that diarrhœa or constipation as a primary symptom is rare, totalling only 7 per cent. The second is the frequency of cough. The importance of this as a primary symptom in typhoid does not appear to have been realized, though Willcox (1938) mentions that it may occur. Nearly a quarter of the cases were admitted complaining of cough, and as 17 per cent developed bronchitis and 11.8 per cent broncho-pneumonia, a condition having a mortality of 40 per cent (table I), this raises

an important point. The procedure recommended in many textbooks of tropical medicine is to send specimens of blood from all cases of 'fever of unknown origin' for Widal and culture. In my opinion, many cases that have fever which appears to be due to bronchitis or broncho-pneumonia are not submitted to bacteriological examination, and consequently the true nature of the disease is missed. I consider, in tropical countries, all broncho-pneumonias should be suspected as being due to typhoid and investigated as such.

Headache was complained of in 20 per cent of the cases on admittance; the pain was referred to no particular area more than another. The symptom of rigor (6 per cent) should be noted; these might easily give rise to an erroneous diagnosis of malaria.

The absence of rose spots should be noted. The rash can rarely be seen in an Indian skin.

Enlargement of the spleen is not mentioned, actually it is rare, and when found where malaria and kala-azar are rampant is of no diagnostic value.

Epistaxis occurred in none of the cases.

Whatever symptoms a typhoid case showed on admittance to hospital the mortality is almost the same, with the exception of those admitted with diarrhœa who had a mortality of even twice the average.

Bacteriological tests

In all cases reported the blood was examined for the presence of organisms and for the Widal titre; if either was positive, no further bacteriological examinations were made. The patients were uninoculated, and the necessity of finding a rise in Widal titre, which is essential to establish a diagnosis in inoculated persons, was unnecessary. Unfortunately, the pressure of work on the bacteriologist prevented repetitions of the examination. In spite of these obvious deficiencies, and the arrival of many of the patients at a late stage of the disease, 50 per cent of the cases showed a positive blood culture.

There appears to be a widespread belief that blood culture is only normally positive in the first ten days. In this series though 71 per cent of the positive cultures were obtained in the first ten days as many as 11 per cent were found after the 15th day of the disease, one being as late as the 25th day.

Lantin (1933) investigated the cases showing positive culture in Manila and concluded that a positive culture indicated a bad prognosis, the mortality being three times as high as among negatives; and rising with the length of time the organisms persisted in the blood. The cases here do not support this view. In blood-positive cases the mortality was only 16 per cent compared with the average of 13.7 per cent. The period of the disease in which the organisms were isolated made no difference. This finding is supported by Lewin (1938) who found that

the death rates in mice have no relation to the presence or absence of bacteriæmia.

Types of temperature

The severity of the infection or the prognosis bore no relationship to the type of fever.

Complications

As there is yet no generally recognized specific therapy for typhoid, treatment consists

mainly in the prevention and treatment of complications. Some complication occurred in over 80 per cent of the cases.

Perforation.—That perforation is the complication above all others to be avoided is well demonstrated here where there was a mortality of 100 per cent in the four cases perforating. On the other hand, perforation only occurred in 0.9 per cent of the cases. This figures should be compared with the 4 per cent mortality from

TABLE III

perforation mentioned by Lakin (1937) and the 4.7 per cent of Goodall (1928) and the latter's statement that this complication is responsible for a third of his typhoid deaths.

The other important bowel complication was hæmorrhage; this occurred in only 3.6 per cent of the patients half of whom died. An individual case merits special notice as two very large hæmorrhages occurred, necessitating transfusion, the remarkable feature being that they came on not during the fever, but 10 days and 12 days after the temperature had become normal.

Cases developing diarrhoea in hospital were small in number, both on the low and high diets, but the prognosis of these patients was bad, 40 per cent dying.

Tympanitis developed in 11.5 per cent cases and was associated with a higher mortality (22 per cent) than the average.

Toxæmia.—Marked toxæmia was shown by the development of delirium, hyperpyrexia or cardiovascular failure.

Delirium only developed in 5.2 per cent of the cases of which half recovered without special treatment except sedatives, which is exactly the same proportion which Schwartzman, Baehr and Hollingsworth (1936) obtained by treating delirious cases with serum.

Hyperpyrexia occurred in 5 per cent of the cases and was directly responsible for two deaths, though 24 per cent of the cases showing this symptom finally succumbed to the disease.

Cardiovascular failure.—The exact nature of the condition still seems to be undecided. Porter and Bloom (1935) made a study of the heart in typhoid and concluded that this organ presented no significant problem, anyhow when the disease was treated with high diets. Kelly in a paper by Murray and Kelly (1938) stated

on clinical grounds that the cardiovascular failure was due to myocarditis, and Lakin (1937) appears to have the same view; Ying (1935) however came to the remarkable conclusion that his cases of typhoid showing cardiovascular failure were suffering from beri-beri.

Here cardiovascular failure occurred in 6.5 per cent but had a mortality of 72 per cent. It is of interest to note that the lowest mortality occurred in the case of Physician A where vitamin B in the form of Marmite soup was given.

Cardiovascular failure was responsible for 38 per cent of the total deaths and produced a higher mortality than any other single complication.

Bronchitis and broncho-pneumonia.—These have been discussed under cough as a primary symptom. Box (1937) emphasizes this complication.

Relapses

Relapses occurred in 6.5 per cent of cases. Particulars are shown in table III. The mortality was only 6.9 per cent, *i.e.*, under half the standard death rate. This figure is surprising as it would be expected that in weak convalescents relapsing, there would be a higher mortality.

It was hoped that a study of these cases would give some information on the nature of relapses. Unfortunately it is impossible to say which cases are likely to relapse and consequently special study cannot be made in the main fever. It has been suggested that relapses are likely to occur where the rise in blood agglutinins is low in the primary attack, but case A 142 is against this for even a Widal of at least 1 in 1,000 was not sufficient to prevent a relapse. Blood culture was positive in 64 per cent of the cases in the relapse where it was investigated.

Deaths.—Death occurred in 13.7 per cent of the cases. The death rate was approximately the same in each unit despite the different treatments. It is worth noting though not necessarily of significance that all the cases of perforation occurred where the lowest diet was given. Other bowel complications were equal in each unit. This fact demonstrates conclusively that small doses of purgatives as given in unit C have no adverse effect, and I am convinced myself that they give the patient considerably more satisfaction and remove more toxins than do any type of enema.

Over 40 per cent of cases died after the third week of the disease and the mortality was not influenced by the age of the patient.

Treatment.—Financial considerations making the use of Felix serum impossible, routine dietetic treatment had to be relied on. The results obtained by the classical semi-starvation, modified semi-starvation with vitamin preparations

and fairly high diet with modified 'open bowel' methods were almost exactly the same.

Prognosis.—The general mortality is 13.7 per cent. The prognosis in cases admitted with each symptom and developing each complication are shown in table I. The only really bad symptom on admittance is diarrhoea which cases have twice the normal mortality.

Summary

Four hundred and forty-four cases of typhoid have been studied. The only symptom of adverse significance on admittance is diarrhoea. The blood cultures were found to be the same in recovered or dying cases. The chief cause of death was cardiovascular failure. The few cases of perforation gave 100 per cent mortality and all occurred in patients on a starvation diet. Bowel complications were lowest in those cases treated with small doses of castor oil. The general mortality and length of fever was almost the same in each unit in spite of the different treatments.

I am grateful to Lieut.-Colonel G. R. McRobert, I.M.S., and Dr. M. R. Guruswami Mudaliar for permission to use their case reports, to my house physician Dr. B. Devadoss for his untiring assistance in the collection of the figures, and to Lieut.-Colonel M. M. Cruickshank, I.M.S., Superintendent of the Madras General Hospital, for permission to publish this report.

CLINICAL OBSERVATIONS ON WEIL'S DISEASE IN INDIA

By N. R. KONAR, M.B.

Senior House Physician, Medical College, Calcutta

H. K. ROY, M.B.

Medical Registrar, Medical College, Calcutta
and

M. N. DE, M.B. (Cal.), M.R.C.P. (Lond.)

Professor of Medicine, Medical College, Calcutta, and
First Physician, Medical College Hospitals

(From the Department of Medicine, Medical College,
Calcutta)

THOUGH more than fifty years have elapsed since Weil first described his syndrome, and twenty-five years since Inada and Ido described the causal organism, leptospirosis remains only a recently-studied subject in India. A large number of publications have recently been made from different parts of the world, and 142 authenticated cases of the disease in an obvious clinical form have been reported in the British Isles alone (Manson-Bahr, 1938) during the last three and a half years.

The subject of leptospirosis was discussed recently in this journal (May, 1938) by Dr. L. E. Napier in his editorial capacity; he gave a good clinical description of the disease, but we consider that, as Weil's disease is still rare enough in this country to make its recognition difficult unless its clinical manifestations are familiar and the possibility of its occurrence is borne in mind, this further clinical report seems justified. It is true that epidemics clinically suggestive of Weil's disease have been reported from time to time (Tucker in Bombay in 1907; Franklin in Kashmir in 1913; Paramanand in Bombay in 1922; Pandit and Rao in South India in 1932) but it was not until 1937 that Das Gupta and Chopra reported the first proven case of leptospirosis in India from Calcutta. Since then, Das Gupta (1938) has reported five more cases of leptospiral jaundice in Calcutta. Knowles (1928) and Taylor and Goyle (1931) had foreseen the possible existence of Weil's disease in India and bacteriological advancement in the country has at last fulfilled the vision of these workers.

Weil's disease is a serious malady and its mortality rate as recorded by different writers varies from 10 to 50 per cent of all cases. Specific treatment in the form of antiserum will soon be available and may be of great value if administered early and in large doses.

Five cases of Weil's disease were treated in the ward of one of the writers (M. N. D.) during the last year and a half. In addition to these he had under his care another possible but unproven case. The clinical pictures of Weil's disease are not very familiar in this country as it is interesting to note that only one of the cases was admitted as such and the rest were variously labelled, *viz.* pneumonia, catarrhal jaundice, influenza, and malignant malaria.

The diagnosis should escape no one when jaundice, associated with nephritis and nitrogen

retention, has followed upon an acute febrile illness in which severe headache, agonizing pain all over the body specially in the lumbar region, cramps in the calf muscles, conjunctival congestion and scattered hæmorrhages have been well marked. But the difficulty lies in the fact that at least 50 per cent of these cases never become jaundiced. Hæmorrhages from different mucous surfaces are also not very common. Davidson and Smith (1936) found icterus in 60 per cent and hæmorrhages in only 18 per cent of their cases. Moreover, the icterus usually does not appear before the third day of the disease and hæmorrhages are rare before the second week. The disease in Calcutta is not confined to individuals engaged in any particular occupation (Das Gupta, 1938). Nor has it been particularly associated with rats, though scarcely any house in Calcutta is free from rats.

However, in the very earliest stages the clinical picture is suggestive enough to make justifiable the use of serum before the diagnosis is confirmed. Sudden onset of a severe illness with headache, high fever, severe pain and great tenderness in the limb muscles, marked prostration, conjunctival congestion with slight icteric tinge and slightly enlarged and tender liver, should make one suspect the disease.

The very fact that all the cases that have so far been reported from the Medical College Hospitals, Calcutta, should have come under the eye of one physician would suggest that cases must have been occurring but have not been recognized and that a fuller and wider knowledge of the infection and its manifestations would bring to light other cases. It is with this end in view that these cases are here reported in full.

Case 1.—H. C. B., male, aged 28, cook; admitted on 22nd December, 1937. *Complaints:* Fever, cough, pain on the left side of the chest. *Habits:* moderate smoker. No addiction to alcohol. Previous history regarding health satisfactory. A year ago he had an attack of pneumonia.

History of the present illness.—Four days prior to admission the patient had a sudden attack of fever with chill, rigor and vomiting. He had severe headache and marked pain all over the body, especially in the calf muscles and over the left side of the chest. The urine was highly coloured, the bowels constipated. The vomiting, which was present at the onset, persisted and at the time of admission the patient was unable to retain even sips of water.

Physical examination.—Temperature 100°F.; pulse 100, and respiration 26 per minute. Patient looked toxic and was restless, conjunctivæ congested and icteric. Tongue dry and coated, throat moderately congested. Superficial lymph glands not enlarged. Liver enlarged one finger's breadth below the costal margin; it was soft and tender. Spleen not palpable. No other abnormality detected.

Laboratory examinations.—Blood: hæmoglobin 70 per cent. Red blood cells—3,950,000 per c.mm. White blood cells—16,875 per c.mm. Polymorphonuclears 85 per cent; lymphocytes 11 per cent; monocytes 2 per cent; eosinophiles 2 per cent. No malarial parasites seen.

Urine—Slightly hazy, deep yellow; specific gravity 1010; alkaline, albumen and bile—present; occult blood—nil. No other abnormality detected.

Van den Bergh reaction—Immediate direct strongly positive; bilirubin content—16 units. Direct examination of 6 smears from peripheral blood under the dark-ground illumination showed no leptospira. Examination of half a dozen films stained by Tribondeau's modification of Fontana's method showed no leptospira.

Blood culture (6th day of disease):

(a) on glucose broth—sterile,

(b) on Fletcher's medium—a scanty growth of leptospira on the 30th day of culture.

Animal inoculation (6th day)—Two young guinea-pigs were given intraperitoneal injections with the patient's blood. Both the animals developed typical signs of leptospiral infection and died on the 7th and the 8th day of inoculation, respectively.

Urine examination for leptospira—Centrifugalized deposits of five specimens of freshly-voided urine obtained between the 15th and 25th day of illness were examined under the dark-ground illumination with negative results. Protection experiments—The patient's serum protected guinea-pigs against the strain isolated from the patient himself, but failed to do so in guinea-pigs inoculated with a different strain.

Progress of the case.—Fever, headache, vomiting and toxæmia persisted for the first four days after admission. Temperature gradually settled down on the 8th day of the disease. On the 9th day it shot up to 101°F. but came down again to normal on the next day. There was a secondary rise of temperature to 102°F. on the 21st day of the illness. This, however, came down to normal within twenty-four hours. Bowels were constipated throughout the illness. The urinary output was quite good varying between 30 and 60 ounces in twenty-four hours. The jaundice gradually lessened and was completely absent a month after admission. Throughout the whole course the patient was markedly weak and prostrated.

Case 2.—M. B., male, aged 28, bearer; admitted on 14th October, 1938. *Complaints:* Bleeding from the gums, passage of tarry stools, jaundice, marked diminution in the urinary output, hiccough and vomiting.

History of the present illness.—Fifteen days prior to admission, the patient had a sudden attack of fever with headache, chill, rigor, vomiting and pain all over the body. The fever lasted for two days. He started having melena and bleeding from the gums three days prior to admission. The day of illness in which jaundice was first noticed could not be ascertained.

Physical examination.—Patient looked seriously ill and was in a semi-conscious state; temperature 98°F.; pulse 88 and respiration 26 per minute; jaundice marked; tongue dry and coated; conjunctivæ congested; gums bleeding; petechial spots scattered over the body; face, legs and feet oedematous; superficial lymph glands not enlarged; abdomen tympanitic; liver soft, tender, two fingers' breadth below the costal margin; spleen not palpable; heart sounds faint; no other abnormality detected.

Laboratory examinations.—Blood: hæmoglobin 45 per cent. White blood cells—12,000 per c.mm. Polymorphonuclears 90 per cent; lymphocytes 9 per cent; monocytes 1 per cent. No malarial parasites seen.

Urine—Deep brown, alkaline, hazy, specific gravity 1010, albumen and bile present; occult blood test negative. Microscopically—bile stained epithelial cells.

Blood culture—No growth; agglutination reaction to enteric group of bacilli—negative. Wassermann reaction of blood strongly positive.

Blood chemistry—Urea 410 mgm. per cent; N.P.N. 245 mgm. per cent; cholesterol 262 mgm. per cent. Van den Bergh reaction—immediate direct strongly positive; bilirubin content—32 units.

Blood examination for leptospira—Blood was taken for serological tests alone, the patient having come to the hospital on the 16th day of illness. As the serum did not give any significant reaction with the local strain and as it failed to protect young guinea-pigs against this strain, a little of it was sent to

Professor Schöffner's Laboratory at Amsterdam. The serum reacted with a rat strain isolated from a field rat (*R. brevicaudatus*) in Semarang (Java) in a high dilution (1 in 1,000).

Progress of the case.—The jaundice and coma deepened and complete suppression of urine followed. Bleeding from the gums continued. The temperature ran a subnormal course except on the day of death, when it went up to 99°F. Blood pressure recorded on the day prior to death was 130/90 mm. of Hg. Patient died on the 18th day of illness.

Case 3.—M. A., male, aged 55, labourer; admitted on 18th March, 1939. *Complaints:* Fever and jaundice. Previous history regarding health satisfactory.

History of the present illness.—Eighteen days prior to admission the patient had an attack of fever which came on insidiously without any chill, rigor or vomiting. He had headache and marked pain all over the limbs. He developed jaundice three days after the onset of the illness. His urine was high coloured and bowels were constipated.

Physical examination.—On admission the temperature was 97°F.; pulse 100 and respiration 24 per minute; prostration marked; tongue very dirty; conjunctivæ markedly icteric. Superficial lymph glands not enlarged; liver soft, tender and enlarged, one finger's breadth below the costal margin; spleen not palpable. A few petechial spots on the chest and the back; no other abnormality detected.

Laboratory examinations.—Blood: hæmoglobin 65 per cent. Red blood cells—3,400,000 per c.mm. White blood cells—15,600 per c.mm. Polymorphonuclears 88 per cent; lymphocytes 11 per cent; monocytes 1 per cent. No malarial parasites seen.

Urine—Brownish, acid, hazy, albumen—present. Bile—nil. Indican—present, urobilinogen test strongly positive. Occult blood test positive. Microscopically a few pus cells, occasional red blood cells and a fair number of hyaline and granular casts.

Fæces—Occult blood test positive.

Blood and urine cultures—No growth. Widal reaction negative.

Blood chemistry—Urea 32 mgm. per cent; N.P.N. 22 mgm. per cent, calcium 8 mgm. per cent; chloride 410 mgm. per cent. Van den Bergh reaction—immediate direct positive; bilirubin content—11 units.

Serological reaction for leptospira—The serum of the blood taken on the 17th day of the disease reacted with 'Strain Chopra, Calcutta' (Das Gupta, 1938) in 1 in 80 to 1 in 160 dilution. The leptospira could not be isolated from urine.

Progress of the case.—The temperature was almost normal except on the 20th day of illness when it went up to 101°F. It came down on the next day and remained normal till his discharge. During the period, following a dose of calomel, his temperature rose to 102°F. but came down to normal within twenty-four hours. Along with this rise of temperature, his stools became very loose and continued to be so for a week. The urinary output was all along low, varying between four and thirty ounces in twenty-four hours. Bowels were very constipated except during the period following the intake of calomel. Generalized weakness was a very prominent feature. The jaundice gradually lessened and disappeared completely within a month from the onset of illness.

Case 4.—G. B., male, aged 40, gardener; admitted on 28th November, 1938. Patient was admitted in a semi-conscious state; he was having persistent hiccough and it was learnt that he had not passed any urine during the last twenty-four hours.

History of the present illness.—Seven days prior to admission the patient had a sudden attack of fever with chill, rigor and vomiting. The fever lasted for seven days. Since the morning of the day of admission, patient had hiccough and became drowsy. His bowels were constipated.

Physical examination.—Patient looked seriously ill, was semi-conscious and at times delirious; temperature 96°F.; pulse 70 and respiration 28 per minute; conjunctivæ congested; tongue dry and heavily coated;

jaundice marked; hicough present; abdomen tympanitic; liver soft, tender and enlarged two fingers' breadth below the costal margin; spleen not palpable; heart sounds faint, rhythm irregular; no other abnormality detected.

Laboratory examinations.—Blood: hæmoglobin 65 per cent. Red blood cells—3,760,000 per c.mm. White blood cells—12,500 per c.mm. Polymorphonuclears 80 per cent; lymphocytes 15 per cent; monocytes 3 per cent; eosinophiles 2 per cent. No malarial parasites found.

Blood chemistry.—Urea 150 mgm. per cent; N.P.N. 120 mgm. per cent; cholesterol 133 mgm. per cent; chloride 398 mgm. per cent. Van den Bergh reaction—immediate direct strongly positive; bilirubin content—45 units.

Serological test for leptospirosis.—As the serum did not give any significant reaction with the local strain, a little of it was sent by Dr. Das Gupta to Professor Schüffner's Laboratory at Amsterdam where it reacted with strain 'Andaman CH' in 1 in 30 dilution. No leptospira could be isolated from the blood or urine of the patient.

Progress of the case.—The patient became more and more drowsy. Complete suppression of urine ensued. Patient ultimately died on the 9th day of the disease.

Case 5.—G. H., male, aged 20, unemployed, admitted on 17th June, 1939. **Complaints:** Fever, headache, pain all over the body. Previous history regarding health satisfactory. Moderate smoker but not addicted to alcohol.

History of the present illness.—Three days prior to admission patient had a sudden attack of fever with chill, rigor and vomiting. He had severe headache and marked pain all over the body. The urine was clear. Bowels were constipated.

Physical examination.—Temperature 100°F.; pulse 100 and respiration 26 per minute. Patient looked toxic, dull and apathetic. Skin: generalized erythema. Conjunctivæ congested; tongue heavily coated; throat markedly congested. There was a slight icteric tinge of the conjunctivæ. Superficial lymph glands not enlarged. Liver soft, tender and enlarged one finger's breadth below the costal margin. Spleen not palpable. No other abnormality detected.

Laboratory examinations.—Blood: hæmoglobin 75 per cent. Red blood cells—4,100,000 per c.mm. White blood cells—10,608 per c.mm. Polymorphonuclears 78 per cent; lymphocytes 18 per cent; monocytes 2 per cent; eosinophiles 2 per cent. No malarial parasites found.

Urine.—Light yellow, hazy, alkaline, specific gravity 1020, albumen—present. Bile—nil. Occult blood test was negative. Microscopically no pus cells, no red blood cells, no casts.

Fæces.—Occult blood test positive.

Blood culture and Widal reaction were negative.

Blood chemistry.—Urea 33 mgm. per cent; N.P.N. 25 mgm. per cent; cholesterol 130 mgm. per cent; chloride 384 mgm. per cent. Van den Bergh reaction—immediate direct positive; bilirubin content—4 units.

Serological reaction for leptospirosis.—The serum of the blood taken on the ninth day of the disease reacted with 'Strain Chopra, Calcutta' (Das Gupta, 1938) in 1 in 80 to 1 in 160 dilution. Leptospira were isolated from the urine taken on the 10th day of illness.

Progress of the case.—The temperature went up to 102°F. on the evening of admission. It ran a remittent course varying between 99°F. and 101°F. On the twelfth day of disease, temperature came down to normal. The patient had a secondary rise of temperature to 100°F. on the twenty-fourth day of the disease which persisted for four days. The headache and pain all over the body persisted for a week from the onset of illness. The urinary output was quite good all along; it varied from 50 to 70 ounces in twenty-four hours. Bowels were very constipated. Prostration was marked.

In the following case, we suspected the possibility of leptospirosis but unfortunately the

diagnosis could not be confirmed by special investigations. In fact, there was no time for such investigations as the patient died within a short time of his admission.

Case 6.—S. M., male, aged 35, plumber, admitted on 19th September, 1939, in an unconscious state on the 6th day of illness with a history of fever for the first two days. On the morning of admission patient felt very weak. He became unconscious in the afternoon. Bowels were said to be constipated. Urine was small in quantity and high coloured.

Physical examination.—Patient unconscious and at times hoisterous. Conjunctivæ markedly icteric. Abdomen tympanitic. Liver and spleen were not palpable. No evidence of paralysis or paresis. Pupils equal and reacting to light. Neck soft. Plantar responses flexor. Tendon jerks slightly exaggerated. No other abnormality detected.

Laboratory examinations.—Blood: hæmoglobin 65 per cent. White blood cells—6,864 per c.mm. Polymorphonuclears 82 per cent; lymphocytes 13 per cent; monocytes 2 per cent; eosinophiles 3 per cent. No malarial parasites found.

Urine.—High coloured, clear, slightly alkaline, albumen present. Acetone—trace. Bile—present. Microscopically a few pus cells and epithelial cells. Biochemical and serological investigations could not be undertaken.

Progress of the case.—The depth of coma gradually increased. Urinary output was markedly diminished. On the morning of his death, his temperature shot up to 101.5°F. Pulse became imperceptible, respiration hurried, and patient expired on the 7th day of his illness from pulmonary oedema.

Comments

It will be noticed that though the occupation of the different patients varied, all of them belonged to the poorer and working class of society. They resided in rooms on the ground floor where rat infestation is quite common. It is probable that rats were not responsible for the infection in these cases; they might have derived the infection from water or mud. The work of a gardener, labourer and plumber particularly favours such a mode of infection. Wolbach and Binger (1914) in America and Taylor and Goyle (1931) in the Andamans have been able to demonstrate leptospira in water and soil of places where leptospirosis was prevalent. No work in this connection has yet been carried out in India. Though rat infestation in the houses of Calcutta is quite common, leptospiral infection of the local rats is extremely rare. Knowles and Das Gupta (Knowles, 1932) found only two rats infected out of 193. Das Gupta (1938) reported that none of the 162 rats he examined showed leptospira. Nor was the agglutination reaction of the serum of these rats with local human strain of leptospira positive in any case. The observations of Taylor and Goyle (1931) in the Andamans also disprove the direct rôle of rats in the epidemiology of leptospirosis.

It will be further seen that the diagnosis of leptospirosis is particularly difficult in the tropics. Apart from diseases such as influenza, catarrhal jaundice, secondary syphilis, and septicæmia, tropical conditions such as malaria,

black-water fever, dengue, typhus, relapsing fever, and yellow fever have to be specially borne in mind. The first step in diagnosing leptospirosis is to remember the possibility of the disease. The next essential step is to undertake full bacteriological and serological tests. Regarding the latter, it is evident from case 2 and case 4 that it is not sufficient to test the serological reactions with local strains alone. It is necessary to match the reactions against strains isolated from different parts of the world. This has also been pointed out by Das Gupta (1938).

Summary

(1) A brief history of leptospirosis in India has been given.

(2) Complete case notes of five proved cases and one suspicious case have been recorded.

(3) Possible sources of infection in the reported cases have been discussed. It has been pointed out that water and soil may play an important part in the epidemiology of the Indian leptospirosis.

(4) Difficulties in the diagnosis of leptospirosis in the tropics have been pointed out. A plea has been made for the undertaking of full bacteriological and serological tests (using widely different strains of the organism) in all suspected cases.

Our sincerest thanks are due to Prof. B. M. Das Gupta for the special bacteriological and serological investigations carried out in all the cases. We are grateful to Lieut.-Col. J. C. De, I.M.S., Superintendent, Medical College Hospitals, Calcutta, for his kind permission to publish the cases, to Prof. P. De for the biochemical reports, to Prof. B. P. Tribedi for the bacteriological reports and to Dr. J. C. Banerjee for his valuable suggestions.

TREATMENT OF LOBAR PNEUMONIA WITH M. & B. 693

By N. D. JEKYLL

CAPTAIN, I.M.S.

Indian Military Hospital, Peshawar

MUCH has been written about the treatment of lobar pneumonia with M. & B. 693 (2-sulphanilyl-aminopyridine), but it might be of some interest to record its action on pneumonias met with in the North-West Frontier Province of India.

During the past winter 15 cases have been treated with this preparation in the Indian Military Hospital, Peshawar. The majority were young healthy males leading an active life, and consequently one would not expect a high mortality rate. For the same period in 1937-38 the death rate in this hospital from lobar pneumonia was ten per cent.

Unfortunately, no typing of the organism was carried out.

Administration of the preparation was commenced on the second, third or fourth day of the disease, the cases previously receiving local treatment and, if necessary, hypnotics at night.

A typical case.

The results, which are also given in the accompanying table, were as follows :—

Eleven patients had an immediate response in 24 hours, their general condition being considerably improved and within 48 hours the temperature had fallen to normal by crisis.

One patient immediately responded by lysis, his temperature being normal by the eighth day.

One patient showed an immediate response, but developed signs in the opposite lung. Continuation of the preparation brought about a crisis on the eighth day.

One patient responded in 72 hours.

The remaining patient was admitted in an extremely toxic condition requiring oxygen and stimulants before administration was started and died after receiving only four tablets.

With this single exception it was found that none of the patients required any other drugs,

as their general condition never gave rise to anxiety. They slept well and were not troubled by dyspnoea, cough, pain, or delirium after the onset of treatment with M. & B. 693. Whereas

onset of the treatment being nearer the crisis or to the formation of some immunity.

(2) Where less than a total of eight tablets were given on the first day of administration or

TABLE
Summary of cases treated with M. & B. 693

Case number	Severity of condition	Day of onset of treatment	Day temp. reached normal	Day pulse reached normal	Day resp. reached normal	Temp. at onset of treatment	Temp. 24 hrs. after onset	Dosage number of tablets	Number of days	Complications	Further progress
1	+	3	5	5	8	103.8	102.0	20	3rd to 5th	None	Rapid recovery.
2	+	4	5	7	9	103.0	97.8	20	4th „ 6th	„	„

In column 2 { 0 = Case of average severity.
+ = Case of marked severity.
++ = Case of extreme severity.

in past years many cases have required constant nursing, oxygen and stimulants, this year no case treated with this preparation has needed any of these.

The average day on which the temperature reached normal was the fifth day, the pulse rate on the sixth day and the respiration rate on the ninth day.

The dosage which seemed to give the best results was a total of eight 0.5 gramme tablets on the first day of treatment made up of an initial dose of four tablets followed up by two tablets four hourly. On the second and third day a daily total of six tablets made up of two tablets four hourly and if necessary a further three tablets on the fourth and fifth days in four-hourly doses of one tablet. No tablets were administered during the night.

One of the above patients had very slight vomiting, but showed no other ill effect. Systematic blood counts were carried out and no ill effect was observed.

The following two points were noted during administration:—

(1) Treatments started on the fourth day appeared to give slightly better results than those started earlier. This may have been due to the

less than six on the second day the cases did not tend to show such a dramatic recovery.

THE DIAGNOSIS OF KALA-AZAR IN DISPENSARY PRACTICE

By L. EVERARD NAPIER, M.R.C.P. (Lond.)
School of Tropical Medicine, Calcutta

Two plates illustrating the aldehyde (Napier, 1921) and the antimony (Chopra, Gupta and David, 1927) tests were prepared at the request of a senior administrative officer in a province where kala-azar is prevalent. This short note on diagnostic methods in kala-azar has been prepared as an introduction to these plates and the accompanying diagnostic tables.

The clinical picture in a well-established case of kala-azar is very characteristic, but in all kala-azar endemic areas there are other conditions that may simulate this disease so that it is seldom justifiable to make a diagnosis solely on the clinical findings. On the other hand, practically all the signs and symptoms of kala-azar may be absent even in a patient who has had the disease for six months or more. Therefore, in every case of suspected kala-azar, or of undiagnosed fever, of splenic enlargement or of

PLATE XXI
Aldehyde (Napier) test

Positive.

Doubtful (+).

Doubtful \pm .

Nega

The technique

Take 5 ccm of blood from a vein with a sterile and dry syringe, and allow it to stand until the serum separates.

Place 1 ccm. of clear serum in a test tube, $\frac{1}{2}$ inch by 4 inches, and add one drop of commercial formalin. Mix well by rotating the tube between the hands.

Reading the result

The final result should be read at the end of 24 hours, but with experience a very good idea of the probable result will be obtained in half an hour.

Positive. Solid, white and completely opaque (hard-boiled egg); no light transmitted through the serum (plate XXI, a). If complete opacity is produced in 20 minutes, the result is +++, if in two hours, ++, and if in 24 hours, +.

Doubtful (+). Solid, with milky appearance which looks opaque against a dark background, but shows the shape of the window when held up to the light, after 24 hours (plate XXI, b).

Doubtful \pm . Solid, slightly milky but quite transparent, after 24 hours (plate XXI, c).

Negative (-). Solid but crystal clear, after 24 hours.

Negative - ive. Serum unchanged (fluid), after 24 hours (plate XXI, d).

Interpretation of results

Size of spleen	Aldehyde test reading	+++, ++, or +.*	(+)	\pm	(-)	- ive
Below the navel	Kala-azar	Doubtful	Not kala-azar.	Not kala-azar.	Not kala-azar.
Four inches or more below costal margin but not below the navel.		Kala-azar	Probably kala-azar.*	Possibly kala-azar.	Probably not kala-azar.	Not kala-azar.
Two inches or more but less than four below costal margin.		Kala-azar	Kala-azar*	Possibly kala-azar.	Probably not kala-azar.	Doubtful
Palpable, but less than two inches below costal margin, or not palpable.		Kala-azar	Kala-azar*	Possibly kala-azar.	Doubtful	Doubtful

* Except when there are obvious signs of advanced tuberculosis or leprosy.

PLATE XXII
Antimony (Chopra) test

Positive.

Doubtful.

Negative.

The technique

Take 1 c.cm. of blood from a vein with a sterile and dry syringe, and allow it to stand until the serum separates. The serum is diluted ten times with double distilled water in a capillary pipette with a rubber teat and is put into a miniature test tube, $2\frac{1}{2}$ inches to 3 inches long with an internal diameter of 3 to 4 mm. A 4 per cent solution of urea-stibamine in double distilled water is then slowly run down the inside of the tube from a clean capillary pipette.

Reading the result

Positive. This is indicated by a heavy flocculent precipitate forming almost immediately (plate XXII, a); this settles as a flocculent mass in the course of half an hour or so (plate XXII, b).

Doubtful. This is indicated by a fine granular precipitate which settles more slowly (plate XXII, c), but forms a more compact mass at the bottom of the tube (plate XXII, d).

Negative. In a negative result no precipitate occurs (plate XXII, e).

Interpretation of results

Antimony test reading. Size of spleen	Positive	Doubtful	Negative
Below the navel ..	Doubtful	Not kala-azar.	Not kala-azar.
Four inches or more below costal margin but not below the navel.	Probably kala-azar.	Doubtful	Not kala-azar.
Two inches or more but less than four below costal margin.	Kala-azar*	Doubtful	Probably not kala-azar.
Palpable, but less than two inches below costal margin, or not palpable.	Kala-azar*	Doubtful	Doubtful

* Except when there are obvious signs of advanced tuberculosis or leprosy.

unexplained continued ill health, in a kala-azar endemic area, one or more of the simple serum tests for this disease should be carried out, even if one of the methods of demonstrating the presence of the causative organism is not adopted.

Methods of demonstrating the presence of the parasite

Examination of the peripheral blood for parasites is a simple method that should not be neglected. If four films are taken and made in such a way that most of the white cells are drawn to the end of the film to form a 'leucocytic' edge, as described by Wright for the opsonic index technique, this edge can be rapidly examined. By examining four such films, which will take only about 20 minutes, parasites can be found in 60 per cent of cases of kala-azar.

Other methods of demonstrating the parasite are sternal puncture and spleen puncture.

Sternal and spleen punctures.—We do not propose to describe the technique of either of these methods; for this, reference may be made to two recent papers in this journal (Napier, 1936, and Napier and Sen Gupta, 1938).

For the last three years we have been doing sternal puncture as a routine examination in all forms of anæmia. In a certain number of cases of anæmia due to kala-azar we found leishmania in the smears made from the sternal fluid; we reported this in the *Annual Report of the Calcutta School of Tropical Medicine* for 1937. During the last 18 months we have adopted sternal puncture as a routine examination in kala-azar, only doing spleen puncture in those cases in which there was a negative finding by the former method.

Our findings to date can be summarized as follows:—

Untreated kala-azar

Leishmania found in sternal puncture material	51
Leishmania not found in sternal puncture but found in spleen puncture material	15
Leishmania not found in smears from either spleen or sternum, but grown in culture from spleen puncture material	2
	68

The positive sternal puncture findings are thus 75 per cent.

If we exclude the first 27 cases, reported in our 1937 annual report, on the grounds that in all these early cases the films were not searched specifically for leishmania, the numbers are reduced to:—

Leishmania found in sternal puncture	33
Leishmania not found in sternal puncture	8

The positive findings in this series are 80.5 per cent. The present writer (1923) found leishmania in 90.8 per cent of first spleen punctures.

Thus, even if one takes the more favourable figures, the sternal puncture findings are considerably inferior to the spleen puncture findings. In the average spleen puncture there are parasites in large numbers in every field, but in a

sternal puncture smear, even when parasites are present, a search has often to be made before they are found. It is important to emphasize this, as recently there has been a tendency in the literature to suggest that sternal puncture can now replace spleen puncture entirely (Chung, 1938; Schretzenmayr and Lancaster, 1938).

The advantages of sternal over spleen puncture are that it is probably safer in inexperienced hands, though the writer claims over six thousand spleen punctures without any untoward results, and that it can also be done in early cases in which the spleen is not palpable.

Cultural methods.—These will only be possible when the services of a well-equipped laboratory are available. Cultures of the peripheral blood will be 'positive' in every untreated case of kala-azar, if the technique is faultless, but it may be three weeks or even a month before there is any sign of growth in the medium. Cultures can also be made from the spleen puncture or sternal puncture material, and in both these instances an earlier positive finding may be expected.

The limitation of the serum tests

The changes in the blood which are demonstrated by the serum tests take place slowly. The antimony test is the more delicate test and therefore signs of these changes will appear earlier; on the other hand, in all cases of splenomegaly the antimony test is liable to give equivocal results, and, in some cases of marked splenomegaly in which kala-azar can be excluded, it will give a positive result. The approximate times of development of the two reactions are shown in the table below: in the second column the approximate sizes of the spleen at different stages of kala-azar are given. Histories are notoriously inaccurate in this

TABLE

Duration of symptoms	Probable size of the spleen below costal margin	Aldehyde test	Antimony test
Less than 1 month	0	—ive	—ive
One month ..	Palpable	—ive	±
Two months ..	1 inch	(—) or ±	±
Three " ..	2 inches	± or (+)	± or +
Four " ..	3 "	(+)	+
Five " ..	4 "	+	+
Six " ..	5 "	+ or ++	+
Over six months	6 "	++ or +++	+

disease, as the patient often finds it difficult to state when he first became ill, and therefore the size of the spleen is usually a better indication of the duration of the disease than the history itself. For the interpretation of the results of the serum tests we have therefore used the size of the spleen as one of the criteria.

Advanced tuberculosis and leprosy are mentioned as likely to give rise to confusing, though seldom definitely positive, results.

Schistosomiasis and typanosomiasis, which do not occur in the kala-azar endemic areas in India, may also give confusing results with the serum tests.

Notes on the interpretation of results.—By means of the aldehyde test, in the small-spleen cases, where the infection may be recent and the serum changes not fully developed, it is not possible to make a negative diagnosis, but if the spleen is large one may assume that, had this enlargement been due to kala-azar, the serum changes would be fully developed and the test positive; if it is not positive then there is some other cause for the splenic enlargement and a negative diagnosis may be made. Theoretically, it might be possible for a patient with an already enlarged spleen to contract kala-azar, but in actual experience this appears to occur very seldom.

In the tables of the interpretation of results, where the diagnosis is given definitely as 'kala-azar' or 'not kala-azar', this means that, in an endemic area such as Calcutta, the chances are about 100 to 1 that this diagnosis is correct.

With the antimony test a positive diagnosis can often be made at an earlier date (see table, page 601), but where the spleen is markedly enlarged a positive diagnosis cannot be made with safety and the aldehyde test should be done. That is to say, both tests should be done in all but the very early case, where little help will be obtained from the aldehyde test.

When a doubtful result is given by these tests, one of the methods of demonstrating the parasite (see above) should be adopted, or the patient marked as 'pending' and, if other diseases are excluded, a full course of cinchona febrifuge given. In the early case, there is little disadvantage in delaying the diagnosis as the 'positive-aldehyde' case reacts better to treatment than the 'negative-aldehyde', or early, case. In no circumstances should a few doses of antimony be given as a therapeutic test, but, if in a 'probable' case it is decided to undertake treatment for kala-azar, a full course of treatment should be given and a failure of response to the first few injections should not be considered an indication for discontinuing treatment. Once treatment is commenced diagnosis is made more difficult.

If in a 'pending' case there is no advance in serum reactions in a month's time, the case is probably not kala-azar.

THROMBOCYTOSIS AND SPLEEN EXTRACTS

By C. R. DAS GUPTA, M.B. (Cal.), D.T.M.
 and

L. EVERARD NAPIER, M.R.C.P. (Lond.)
 School of Tropical Medicine, Calcutta

S. M., son of a cultivator, aged about 10 years, was admitted to the Carmichael Hospital for Tropical Diseases for the treatment of microcytic hypochromic anæmia. The boy had not been well for the last two years and was gradually becoming weaker and weaker. He also gave a history of occasional diarrhoea.

On examination he was found to be thin and rather tall for his age. The spleen and liver were not enlarged, no abnormality was found in any of the organs, and there was no manifestation of any involvement of the nervous system.

Laboratory findings

Blood.—This showed a moderate degree of microcytic hypochromic type of anæmia with a very high platelet count—2,187,000 per c.mm. of blood (see table for details of counts, and chart).

Coagulation time, bleeding time and the fragility of the red cells were all within normal limits.

Sternum puncture.—There was a slightly normoblastic reaction, but the marrow did not show any great excess of megakaryocytes.

Fractional gastric analysis.—The acidity was within normal limits and the peptic digestion was complete.

Stools.—Hookworm ova, 300 ova per gramme of stool.

Treatment.—The boy was given ferrous sulphate tablets, grains six, twice daily after food for 21 days—the routine hospital treatment for microcytic hypochromic anæmia. There was some improvement in the blood picture but the platelets continued to be at the higher level.

He was then given two courses of carbon tetrachlorethylene at an interval of seven days, after which the blood picture came down to the original low level and the platelets continued to be high.

The failure of the iron treatment together with the persistent high platelet count led us to think that this was not a simple case of iron-deficiency anæmia, but that some other factor or factors were responsible for this anomalous combination of anæmia and thrombocytosis.

The patient was now put on spleen substance, 5 c.cm. each week intramuscularly for 5 weeks on the assumption that, as the removal of the spleen causes an increase in the circulating

(Continued from previous column)

thrombocytes in many cases of essential thrombocytopænia, conversely administration of this tissue might lead to a reduction in the number of platelets in the peripheral circulation, as was observed by Troland and Lee (1938) in animals after administration of splenic extracts from patients with essential thrombocytopænia.

This treatment was associated with a reduction in the number of circulating platelets from 2,187,500 to 401,400 per c.mm. in a period of 5 weeks, though the blood picture still continued at a low level. However, a second course of ferrous sulphate—gr. 12 each day for 21 days—now brought up the blood almost to the normal level—the blood platelets remaining within normal limits. The patient was kept under observation for another three weeks, during which time the blood picture and the platelets remained at the normal level.

There are two hypotheses—
(i) A hyperfunction of the spleen which leads to over-destruction of platelets with a consequent reduction in the number of platelets in the blood (Kaznelson, 1916). The effect of splenectomy in correcting the disorder in these cases is explained as due to the removal of the culprit organ.

(ii) A primary megakaryocyte deficiency which is due to the depressant action of the spleen on the marrow (Frank, 1915). The removal of the spleen means the withdrawal of the depressant action; the marrow then functions normally producing and sending to the circulation the requisite number of platelets.

This latter hypothesis seems to be more reasonable as hæmolysis and thrombocytolysis, as functions of the spleen, are dependent on theories which are not tenable on the basis of our present-day knowledge. The most powerful

Discussion.—Of the various functions attributed to the spleen, regulation of the thrombocytes is undoubtedly one, as is illustrated by

the beneficial effect of splenectomy often seen in suitable cases of essential thrombocytopænia (Spence, 1928). But how this is brought about has not been conclusively proven.

argument against an active splenic hæmolysis is the blood crisis invariably seen after splenectomy. The crisis occurs within a few hours of the operation with a profuse shower of nucleated erythrocytes in the peripheral circulation as if the regulating mechanism of erythropoiesis was thrown out of gear by removal of the spleen. The blood crisis seen after splenectomy cannot be explained as being due to the removal of a hyper-hæmolyzing organ taxing the bone marrow, as the effect in such a case would have been a slow and gradual recovery of the marrow and disappearance of all the pathologic cells from the circulation. As it stands, the crisis is only explicable as due to an inter-relationship between the spleen and the marrow. But this inter-relationship between the spleen and the marrow is not clearly understood as the action of the spleen on the marrow is not always the same—sometimes the spleen stimulates, while at other times it inhibits the action of the bone marrow.

TRANSPLANTATION OF URETERS FOR INOPERABLE VESICOVAGINAL FISTULA

A REPORT OF TWO CASES

By HERSCHEL C. ALDRICH, B.A.,
M.D. (Ohio State Univ., U. S. A.)

American Methodist Mission Hospital, Nadiad

COFFEY (1911) and Stiles (1911) described somewhat similar techniques for the transplantation of ureters. Operations for transplantation previous to this date, suggested by various surgeons, were not satisfactory, and resulted in a high mortality rate. Coffey modified his first technique, designating it as Coffey II (1927), and Coffey III (1931). It is not until quite recently that more than a few cases have been operated on successfully for the transplantation of ureters to the rectum. Turner (1929) reported 17 cases by the Stiles' technique. Woodman (1936) reported a series of cases also by the Stiles' technique. Orr (1937) reported a series of 13 cases (5 cases by Coffey II, 1 case by Coffey III, high transplantation 1 case, and 6 cases by the Stiles' technique). In this series of 13 cases, the 5 cases done by the Stiles' technique were entirely successful, whereas those done by the other methods were unsatisfactory for various reasons.

Essentials for a successful transplantation are :—

(1) The anal sphincter must be undamaged and in good condition, in order that the urine may be retained in the rectum without leaking.

(2) The ureters must be transplanted one at a time, with a sufficient interval between the two operations to permit the first kidney to recover from the temporary incapacity accompanying the pyelo-nephritis that invariably sets in immediately following the implantation of the ureter into the septic rectal field.

(Continued from previous page)

Morawitz tries to explain this seemingly anomalous function of the spleen as a 'conditioned' function of the spleen. In the case cited above, the 'conditioned' action of the spleen is well illustrated. The patient had anæmia with thrombocytosis denoting inhibition of erythropoietic function with stimulation of the megakaryopoietic function. The administration of spleen substance effected an immediate correction in the thrombocyte formation and paved the way for the correction of the anæmia with iron, which had not responded previously to the same dose of iron.

(3) The distal $2\frac{1}{2}$ inches or 3 inches of the transplanted ureter must have some suitable drain placed within its lumen to prevent a complete destruction of kidney function from a blockage of the lumen, which might occur if this were not done, because of the rather sharp reaction, with oedema, that must occur from this sepsis.

Vesicovaginal fistula is a very common condition in India; where, as a rule, most cases are delivered in their homes by untrained *dais*. Many of these cases of vesicovaginal fistula are totally beyond repair surgically, as frequently the whole bladder trigone, together with the sphincter and a portion of the urethra are completely torn out. In such cases the transplantation of the ureters to the rectum or sigmoid, preferably by the Stiles' technique, is to be strongly recommended. Where this is not done, the woman is outcaste by her husband and friends. She is put to no end of discomfort from the excoriation and irritation of skin, and the foul smell, which are a part of the continuously dripping urine. Following a successful transplantation, the woman is completely freed from this inconvenience, and can live a normal life, once again taking her place in the family.

We are reporting the two following cases operated on by the Stiles' technique; four separate operations in all. Both these women are very pleased with the outcome of the operation. One of them has now been at home for a period of about a year and a half; the other has recently been discharged from the hospital.

Case 1.—Female, 17 years of age, Hindu, Patel by caste. This woman first presented herself at our hospital on 24th June, 1937, with the history of having had a forceps delivery in another hospital some three months ago; following this there was a continuous dripping of urine, and a partial paralysis of both legs. Patient could only walk with the greatest of difficulty. This was her first pregnancy, and the child was delivered at term.

On examination the patient was found to have a rather markedly contracted pelvis. Vaginal examination:—The entire base of the bladder, together with the sphincter, urethra, and lower portion of the triangular ligament completely torn out. The anal sphincter was found to be in good condition, with normal control. This patient was operated on on 30th August, at which time the right ureter was transplanted into the rectum by the Stiles' technique.

Following this operation, for 7 days there was an irregular temperature ranging from a 104°F. to normal. The temperature on the 8th day was normal, and remained so until the second operation on the 16th of September (transplantation of left ureter and ligation of tubes to prevent further pregnancies). Following this second operation, there was a rise of temperature to 101.8°F. on the second day, and an irregular low fever ranging between normal and 99°F. , for a period of some five days, following which it was again normal. After each operation, there was a rather marked decrease in the output of urine from the kidney on the side operated upon, during the first 48 hours, which however, soon returned to normal after this interval.

This patient was discharged on the 29th of September, 1937, with full control of the urine per rectum, and with no complaints.

We have since heard from this patient on two different occasions. We saw her personally six months after the operation at which time she came to the hospital bringing another patient. She was so well satisfied with the result of the previous operation, having no complaints, that she had nothing to say concerning her own case until we inquired from her as to how she was getting along. We again heard from this patient through her husband over a year after the operation, and he reported that she was well and happy with no complaints.

Case 2.—Female, aged 25, Patel by caste. This patient presented herself at our hospital on 26th April, 1938, with a history of having incontinence of urine, following the birth of the last child 12 months ago. She had had six previous uncomplicated pregnancies with three children living. On examination, the entire base of the bladder, together with the sphincter, and a portion of the urethra, were found completely torn away, and there was a continuous dripping of urine through the vagina. The cervix was found to be somewhat soft, and there was a moderate purulent discharge. The patient was scheduled for operation on 2nd May, 1938, at which time the abdomen was opened, and the uterus was found to have the appearance of about a two months' pregnancy. Under the circumstances, we did not feel justified in proceeding with our proposed uterine transplantation, and so the abdomen was closed. The patient was discharged on 18th May, and instructed to return after the delivery of the child. This she did about one year later, 10th April, 1939, with the history of having delivered a baby at term, which died shortly after birth. The right ureter was transplanted to the rectum by Stiles' technique on 14th April, and at this time both tubes were ligated to prevent future pregnancy. The reaction following this operation was very similar to that of the first case reported. There was an irregular temperature ranging from 102°F. to 99°F. for the first week post-operative. The left ureter was transplanted 22 days after the first operation, 5th May. Following this operation the patient had a rise in temperature to 100°F. for one day only, after which there was a slight irregular fever for about a week. The output of urine was as in the first case; that is, much diminished the first 48 hours from the side transplanted. The patient was discharged on 26th May with full control of the urine per rectum, and with no complaints, fully satisfied with the results.

In both these cases it will be noted that there was a rather sharp reaction following the first transplantation and only a comparatively slight reaction following the second. We are considering in the future the use of an autogenous vaccine of *B. coli* made from a culture obtained from the rectum pre-operatively. This might well be done during the week's pre-operative preparation which is routinely followed in the Stiles' technique.

WHAT MAY WE EXPECT FROM THE SUBTOTAL HYSTERECTOMY ?

By L. M. SZAMEK, M.D. (Vienna)

Calcutta

(Former Director of the Frauenkrankeninstitut, Charité in Vienna)

THE question, whether subtotal hysterectomy should be regarded as a recognized method of treatment in cases of uterine lesions has not been decided yet.

Weibel (1939) brought this topic before the Gynaecological Society of Vienna in 1924 and his conclusions were that this operation should be eliminated entirely because of its many disadvantages and replaced by total hysterectomy. This should be the operation of choice every time, when the uterus has to be removed by the abdominal route.

Actually, it should be obvious at first sight that complete removal of an organ may indicate more surgical judgment than a partial one, and that a stump left behind may have troublesome sequels, particularly the later development of a carcinoma.

Therefore, we are not at all surprised that many clinicians have completely discarded subtotal hysterectomy as a worthless operation. But reviewing the literature we find on the other hand that this operation is by no means unanimously condemned.

Almost all the Vienna gynaecologists took part in the general discussion, which followed Weibel's lecture. I myself (1924) had the opportunity of expressing an opinion derived from experiences of 268 cases at Latzko's Clinic in Vienna. Summarizing these, I felt authorized to intercede for the maintenance of subtotal hysterectomy because I was in a position to explain the reasons for our having obtained good results by this procedure. I also called special attention to the factors which had brought this operation into discredit; these factors persist to this day and are due to loose indications.

Subtotal hysterectomy should be reserved for absolutely clean cases, i.e., cases without any sign of inflammation either in the intra-peritoneal parts of the sexual apparatus or of the cervix.

The group of cases in which subtotal hysterectomy is definitely indicated would include conditions such as following: fibroid disease of the uterus, indefinite bleedings such as can be grouped under the term 'metropathia hæmorrhagica', particularly when this condition occurs in relatively young women. To this we would

Note.—The figure in the 'dose' column is the number of grains per day.

Dates are shown as day and month.

Cessation of entries means the particular case was not seen again.

for seven days, and all were passing trichuris eggs a few days later.

Eleven persons, all adults, received four grains of ferrous ammonium sulphate three times a day for seven days and three of them had a repetition of the treatment for a second week. In none of them could any effect on trichuris be observed.

Two adults and one child aged three years were given three, six and two grains respectively, of ferrous sulphate three times a day for three weeks and they passed trichuris eggs throughout the treatment and afterwards.

Discussion

The fact that in our series five cases were negative after one week of treatment is of no significance that iron had any effect on trichuris, because in a series of examinations which were carried out for another purpose some time ago, it was found that 14 out of 40 persons that were positive at the first examination were negative one month later. This particular investigation was conducted on the same persons for a period of twelve months at monthly intervals and absence of eggs in some cases with their re-appearance at a subsequent examination was

noted every month, so one or two consecutive negative examinations when trichuris eggs are not numerous is not evidence of absence of infection even when the direct centrifugal flotation method is used, as was done in this series of examinations and all the others mentioned in this paper.

It is true that our dosage of iron and ammonium citrate was not quite so large as that employed by Vazquez Pausa, except in the case of the three in-patients who received 90 grains of iron citrate a day, and in these the drug was only administered for seven days instead of the ten to fifteen days recommended by the above worker. But in the out-patients eight had three weeks' treatment and five of them had four weeks' treatment, which is much longer than Vazquez Pausa used. It might also be argued that there is no evidence that the out-patients took their medicine, but it is not likely they did not do so or they would not have troubled to return for more.

The anæmia cases that were treated with ferrous iron are not strictly comparable with those of Vazquez Pausa either, because this form of iron is now used in treating certain forms of anæmia on account of its greater absorbability

than the ferric salts, therefore less would remain in the intestine to come in direct contact with the worms. They have been included, however, because in certain forms of successful treatment claimed for trichuris infection and other intestinal helminths, notably the intravenous injection of oil of chenopodium for trichuris by Lambert (1923), the drugs are supposed to act after absorption and alteration in the body and not directly on the worms in the gut. It might be held that iron acts in this way but these cases do not support that idea.

In the light of our practically negative results it is difficult to understand the high cure rate

Conclusion

It is considered that evidence has been produced that the forms of iron in common use for treatment of certain types of anæmia are of no use in removing trichuris.

TABLE II

Showing comparison between D. C. F. and Stoll's counts

District	Number examined	Number positive	Percentage positive	Average number eggs per gramme of stool in infected persons	Percentage + D. C. F. and + Stoll	Percentage + D. C. F. and - Stoll	Percentage - D. C. F. and + Stoll
I	1,558	1,465	94.03	1,031	73.65	26.34	*
II	3,199	2,565	80.11	320	47.41 †	51.81	0.77
III	1,990	1,518	76.28	232	38.80 †	61.19	*

* The records did not permit of this information being obtained so in these instances this figure is included in the column '+ D. C. F. and + Stoll'.

† These differences are statistically significant.

claimed by Vazquez Pausa, even admitting that our treatments were not quite so intensive as his. There is no mention in his paper of the method used for egg demonstration in the faeces, so it is possible that it is in this direction that the explanation may lie. Nevertheless, one must assume that he used the same technique of stool examination before treatment as he did afterwards so this should not be the explanation. However, if a crude smear method were employed, diminution in numbers but not total absence of eggs might lead to failure to find them on post-treatment examination, and hence the claim made that cure had been effected. In this connection table II is of interest as it shows the great influence two different methods of egg recovery have in disclosing the number of trichuris infections when the number of eggs varies. These results have been collected from records of survey work done previously in which both D. C. F. and Stoll's dilution counts were done, the one for diagnosis and the other for estimating the severity of the infections found. The counting method was the same as that originally recommended by Stoll (1923), except that twice the amount of diluent was used, because our experience was that this gave higher counts than the dilution he advocated, possibly because 'camouflage' was reduced. The three different sets of figures represent different districts in which trichuris infection was found to vary considerably both in frequency and intensity. One was in the Bengal Dooars, one in the Assam Valley and the other in the Sylhet district of Assam.

(From the Biochemical Standardization Laboratory, Government of India; All-India Institute of Hygiene and Public Health, Calcutta)

Introduction

As early as 1907, Major-General Sir John Megaw, late Director-General of the Indian Medical Service, called attention to the frequency with which patients seeking treatment for malarial fevers in various hospitals and dispensaries failed to receive the doses of quinine which were prescribed for them. Later, Megaw, Ghosh and Chatterjee (1928) conducted an enquiry on the quality and quinine content of nearly 100 stock solutions obtained at random from various hospitals and dispensaries in Bengal and Assam. The results of this survey revealed that no less than 25 per cent of the samples were 25 per cent or more weaker than the stated strength.

The Drugs Enquiry Committee appointed by the Government of India in 1930-31 (Chopra *et al.*, 1931) collected a large number of quinine tablets from the various provinces of India through the co-operation of the witnesses who tendered evidence before the committee, and found on analysing them that a very large percentage were either adulterated or contained comparatively smaller proportions of quinine than that claimed by the manufacturers.

In the course of an all-India survey of the quality of drugs and medicinal chemicals, the Biochemical Standardization Laboratory has, during the last two years, analysed more than 150 samples of quinine and cinchona preparations. The results indicate, in no uncertain terms, that the unsatisfactory state of affairs, which existed 30 years ago in this country with regard to the deficiency in the strength of quinine mixtures and other preparations of similar category and which had been the subject of repeated warnings, still continues with unabated intensity even to this day. If the condition has changed at all, it has changed for the worse. In view of the gravity of the problem, it seems desirable that the medical profession should be aware of the real situation so that they can co-operate, if necessary, in any programme to eradicate the evil. The present paper is published with this idea in view.

Procedure

(a) *Collection of samples.*—Through the courtesy of the heads of medical and public health administrations of the various provinces of British India, a fairly representative collection of quinine preparations of different categories was made. These included stock quinine sulphate mixtures from the various hospitals and dispensaries, quinine sulphate tablets and powders, quinine bihydrochloride tablets, powders and mixtures, and a host of other quinine and cinchona preparations such as ammoniated tincture of quinine, quinine ethyl carbonate, quinine tannate, 'quinetum', cinchona febrifuge, tincture of cinchona, compound tincture of cinchona, etc. The stock solutions of mixtures were received generally in sealed bottles with a label containing a statement regarding the amount of quinine said to be present per ounce of the mixture. The tablets and powders of the quinine salts and other solid preparations of cinchona were obtained generally in sealed paper packets and, sometimes, in original unbroken glass or tin containers. A few brands of quinine tablets were bought by the officers of the laboratory from the open market, while a few others were presented to the laboratory for analysis by certain commercial firms and independent medical practitioners. The names of the manufacturers were obtained in as many cases as possible, but information regarding the dates of purchase, countries of origin, and conditions of storage of the samples were not available in some instances.

(b) *Methods of analysis.*—The analytical methods employed for the determination of purity of the preparations mentioned above are chiefly those described in the *British Pharmacopæia*, 1932. Cinchona febrifuge samples have been assayed according to the details laid down under 'quinetum' in the *British Pharmaceutical Codex* (1934) and also under 'totaquina' in the *British Pharmacopæia*, 1932.

To determine accurately the quinine content of the stock mixtures of quinine, an aliquot portion (about 10 c.cm.) was first made alkaline with ammonia or caustic soda solution and then extracted with chloroform until complete extraction of the alkaloids took place. The chloroform containing the alkaloid in solution was then removed, treated with about 1 to 2 c.cm. of 95 per cent alcohol, and evaporated to dryness at 110°C. till constant weight was obtained. The residue, which represents the quinine base, was weighed and the weight of the corresponding salt calculated from this figure. The cinchona febrifuge mixtures are treated in almost the same manner as the quinine mixtures, the content of total alkaloids being determined, instead of quinine alone, in such cases.

In a large majority of cases, duplicate analyses have been carried out by two chemists working independently. There are a number of instances, however, where this was not possible, owing to insufficient quantities of the specimens being supplied for analysis by the parties concerned.

Results

A summary of the results of analyses of 100 so-called 'quinine mixtures' is presented in table I. The majority of these samples (82 out of 100) are stock mixtures of quinine sulphate, this being the salt of quinine most commonly employed for routine treatment in Indian hospitals and dispensaries. A few cinchona febrifuge mixtures are also included in the series. Out of a total of 100 samples, only 20 stock mixtures (20.0 per cent) are up to standard or are found to agree with the claims made by the senders, on the labels attached to the bottles. Sixty-four samples have shown a deficiency of quinine, of which as many as 23 samples (nearly one-third) are found to contain less than 60 per cent of the stated strength of quinine. Eleven samples contain from *nil* to about 30 per cent of the quinine salt claimed. This is certainly a very disquieting state of affairs, particularly when it is observed that the majority of the samples reported upon in this paper have been received from government or government-controlled hospitals and dispensaries. If samples could be secured at random from private and charitable dispensaries, there is little doubt that a worse state of affairs would be found to exist.

Slight variations in the quinine content of hospital mixtures may well be ignored and may presumably be accounted for by inaccuracy of

dispensing but, when the deficiency goes down to nearly 80 per cent or less of the stated strength, there is strong reason to believe that some fraud is being perpetrated in the compounding room or at the dispensing counter, and the situation demands prompt remedy. When a mixture is found to contain less than 50 per cent of the stated strength of quinine, it is only to be expected that such a mixture will fail to produce curative effects on patients suffering from malaria.

An interesting observation, for which we were not prepared, is the finding that a few quinine sulphate mixtures actually contained a higher percentage of quinine than that stated on the label. Out of 100 quinine and cinchona mixtures referred to in table I, as many as 16 samples were above standard, a not insignificant figure. Two samples in this group have shown as alkaloidal content nearly 1.5 times as much as the stated strength. This is of course not as bad as a frank deficiency of quinine, but, nevertheless, proves gross neglect and inaccuracy in the dispensing service.

The analytical results of 40 quinine tablets are summarized in table II. Unfortunately details regarding the countries of origin of all the different brands could not be obtained. It may however be stated from the records of 22 tablets at our disposal that they represented samples of Indian, Javanese and European manufacture. Twenty samples (50 per cent)

revealed a distinct deficiency of their quinine contents. Of the 'below-strength' tablets, 9 brands (nearly one-third) showed less than 60 per cent of the stated strength of quinine. One sample contained as low as 6.6 per cent of quinine, and another brand contained no quinine whatsoever. A redeeming feature of this dismal picture, however, is that quite a number of brands contained nearly 90 per cent of the stated strength of quinine. A slight diminution of the strength of quinine of this type, though not desirable on ethical grounds, is not of any serious significance from the therapeutic viewpoint.

To determine whether the quinine sulphate, quinine bishydrochloride, and cinchona febrifuge powders, available in the market or supplied to hospitals or dispensaries for preparing stock solutions for daily prescription service, are of standard strength and proper quality, 28 samples were subjected to analysis, both for the content of active principles and for the presence of any adulterants in them. In table III, the origin, the sources from which the samples were obtained, and the analytical findings of 13 specimens found to be below standard are presented. Though the data in this group are meagre, there is sufficient evidence to indicate that at least some quinine salts and preparations sold in the market are below standard. Most of these samples contained as adulterants, inorganic salts and other cinchona alkaloids. Five

TABLE I

Quantity of alkaloids in 100 samples of quinine and cinchona mixtures

Alkaloid present per cent of claim	Below standard (64)					Approximately correct (20)	Above standard (16)			
	<i>Nil</i>	0-30	30-60	60-80	80-95	95-105	105-120	120-140	150-160	180-190
Number of samples	2	11	12	16	23	20	7	7	1	1

TABLE II

Quinine tablets, their country of origin and analytical results

Total number of samples assayed—40 (Indian 10, foreign 12, unknown 18); up to the standard claimed—20 (50 per cent); below standard—20 (50 per cent).

Country of origin of below standard samples			Quantity of alkaloid in per cent of the claim in below standard samples			
Indian	Foreign	Unknown	<i>Nil</i>	0-40	40-60	80-96
5	6	9	1	3	5	11
25 per cent	30 per cent	45 per cent	5 per cent	15 per cent	25 per cent	55 per cent

TABLE III

Quinine salts and cinchona febrifuge, their country of origin and analytical results

Total number of samples assayed—28 (Indian 16, foreign 10, and unknown 2); up to the standard claimed—15 (53.57 per cent); below standard—13 (46.43 per cent).

Name	Total	Indian	Foreign	Result
Quinine sulphate ..	5	3	2	Inorganic salts and other cinchona alkaloids present.
Quinine bihydrochloride ..	1	1	..	Anhydrous quinine 79.69 per cent.
Cinchona febrifuge ..	5	4	1	Crystallizable alkaloids { 3.3 per cent—1. 45–65 per cent—4.
Quinctum ..	1	1	..	Quinine and cinchonidine 47 per cent.
'Ionized quinine' ..	1	1	..	Quinine trace, Sb, Al and Mg salts present.
Total below strength ..	13	10	3	

samples of cinchona febrifuge (including 'quinctum') gave from 45 to 65 per cent of crystallizable alkaloids. As no definite standards have been fixed for cinchona febrifuge, it is difficult to make any comment on the wide variations that are often noticed from sample to sample. However, as the B. P. 1932 has fixed a definite standard for 'totaquina' (70 per cent crystallizable alkaloids), it seems desirable that all samples of cinchona febrifuge should contain at least 70 per cent of total alkaloids to ensure uniform therapeutic results. Judging from this standard, the cinchona febrifuge samples tested in this laboratory are definitely below par in quality. A sample of foreign origin, contained as low as 3.30 per cent of crystallizable alkaloids, which is the lowest figure on our record. Such a sample is obviously useless and it is surprising how such worthless preparations gain entry into India.

A proprietary preparation called 'ionized quinine' was tested and it was found to contain only a trace of quinine along with certain inorganic metals and salts. It is not known whether a combination of this type can be of any therapeutic utility but certainly the name leads the public to believe that the preparation contains at least a certain amount of quinine. The negligible trace of quinine found in it cannot be expected to do any good in malarial fevers for which the drug is meant to be used. Such preparations are likely to create a false sense of security in the minds of the consumers, and in the interests of the public their sale should be prohibited.

Comment

Medical officers attached to Government or public hospitals in the mofussil areas have repeatedly complained that quinine mixtures and tablets have failed to bring under control cases of malaria under their care. Cases of malaria which are 'quinine resistant' are also

reported from time to time. Clinical reports of this type have often led to a lack of faith in the efficacy of quinine as an anti-malarial remedy. In view of the findings presented above, it seems likely that many fallacies in the field of quinine treatment of malaria may be explained by the fact that quinine administration in proper dosage was not possible in a large percentage of cases, because of the distribution in the hospitals and dispensaries in this country of under-strength quinine mixtures, and of the sale in the Indian market of quinine tablets and quinine salts of inferior quality.

It must be remembered that there are two variables in clinical therapeutics—the *patient* and the *drug*. When a particular remedy fails to bring about an expected cure or alleviation of symptoms, medical men are prone to look for the cause in the *patient* and try to explain the atypical findings, on the basis of the 'susceptibility', 'tolerance' or 'idiosyncrasy', etc., of the individual. The blame is seldom cast on the *drug*, as it is naturally believed to be of standardized quality. This view-point apparently needs revision. Quinine still remains one of the best curative agents in malaria and cases of chronic malaria which have been described as 'quinine resistant' must be very rare, if they exist at all.

Quinine is acknowledged to be one of the most important of all drugs for the malaria-stricken masses of India. The sale of poor quality quinine preparations in India or any tampering with the quality or strength of quinine prescriptions that may take place in the hospitals and dispensaries, therefore, constitutes one of the most cruel forms of injury to the public.

The question that naturally arises in this connection is—'Is there any remedy for such a state of affairs?' Sir John Megaw thought that one of the reasons for the finding of stock solutions of quinine under stated strength in dispensaries might be the fraudulent misappropriation

of quinine by those responsible for the compounding and dispensing of mixtures. Inaccurate dispensing and carelessness on the part of compounders appear also to be important factors, as in a few specimens quantities larger than the stated strength were also found to be present. A suggestion that has been made in the past is that medical men in charge of hospitals and dispensaries should institute a periodic checking of the quality of the stock mixtures of quinine without any previous notice to the dispensary staff. Megaw, Ghosh and Chatterjee (1928) described a simple, roughly quantitative method of determining the amount of quinine in quinine mixtures which does not require elaborate laboratory equipment and which can be carried out in most of the smaller dispensaries and hospitals.

We are not aware of many hospitals and dispensaries where such checking is carried out regularly and zealously. The truth is that medical men in charge of hospitals and out-patients' departments can seldom spare enough time to attend to analytical work and to the checking of dispensary stock and mixtures prepared therein, in addition to their heavy routine duties. Even if some medical officers are enthusiastic enough, they cannot be of much service in appraising the quality of pharmaceuticals and galenicals in general, as expert chemical and pharmacological knowledge are necessary to carry out drug analysis and assay.

The only way by which this state of affairs can be remedied is to institute some form of state control by which regular periodic checking and standardization of drugs, both from hospitals and dispensaries and from the market, may be carried on in special provincial or central government laboratories, specifically set up for the purpose and manned by expert analysts who will be competent to undertake the testing of all kinds of drugs in common use in clinical practice. It seems also imperative that the profession of pharmacy in India be placed on a better footing so that the 'compounders' who compound, dispense, or otherwise distribute drugs are given such training and status as to enable them to discharge in a more able and trustworthy manner the duties and responsibilities attached to their calling. Medicine and pharmacy are intimately related to each other and one cannot make any headway without the other progressing also. The profession of pharmacy is very poorly developed in this country compared to nearly all other civilized countries in the world. Unless this aspect of the problem is dealt with, all sorts of trickery and fraud and inaccuracies in compounding and dispensing service will continue. Definite measures are urgently called for.

Summary

One hundred samples of so-called 'quinine mixture' (including cinchona mixtures), forty samples of quinine tablets, and twenty-eight

specimens of quinine salts and cinchona febrifuge powders, obtained from the various provincial hospitals and dispensaries through the courtesy of the surgeons-general, inspectors-general and the directors of public health were analysed for their purity and quinine (or total alkaloids) content, according to the methods and standards laid down in the *B. P.* 1932, the *B. P. C.* 1934, and other recognized books of reference.

Eighty 'quinine mixtures' were found not to conform to the standards claimed for them. Sixty-four samples (64 per cent) showed a deficiency of quinine. Curiously enough, as many as sixteen mixtures were found to contain a higher percentage of quinine than expected.

Forty samples of quinine tablets, representing several different brands of Indian, Javanese and European make, were tested and in this group also, 50 per cent samples showed a deficiency of quinine content.

Out of twenty-eight samples of quinine sulphate, cinchona febrifuge powders and other miscellaneous solid preparations of this category, thirteen specimens were found to be below standard. Quinine sulphate powders gave tests for the presence of inorganic salts and other cinchona alkaloids indicating the presence of adulterants in them. Cinchona febrifuge specimens were found to contain a considerably lower percentage of the crystallizable alkaloids than that laid down for 'totaquina' in the *B. P.* 1932.

This survey clearly reveals the unsatisfactory state of affairs that exists in this country regarding the importation, sale, and distribution of an essential remedy for malaria, one which is of paramount importance to the malaria-stricken masses of India. It is pointed out that effective control from this kind of fraud in the drug trade and dispensing service can only be exercised by the creation of a state organization for the analysis and standardization of drugs, and also by the improvement of the profession of pharmacy which is at present in a very backward state in India. In view of the gravity of the problem, it seems desirable to institute definite measures to safeguard public health as early as possible.

Acknowledgment

The completion of such an extensive survey is naturally not possible without the co-operation and team work of a number of workers. It is our pleasant duty to acknowledge the help rendered in this work by Mr. R. C. Guha, M.Sc., Mr. K. B. Sehra, M.Sc., and Mr. B. K. Ghosh, M.Sc., our assistant chemists.

AGES OF EPIPHYSIAL UNION AT THE ELBOW AND WRIST JOINTS AMONGST INDIAN GIRLS*

By RAI BAHADUR RAGHUNANDAN LALL, M.B.
Head of Department of Radiology, King George's
Hospital, Lucknow

and

R. S. TOWNSEND, M.C., M.D., M.C.O.G.
COLONEL, I.M.S.

Inspector-General of Civil Hospitals, North-West
Frontier Province, Formerly Reader in Forensic
Medicine, Lucknow University

THE work on which this report is based was carried out by the first writer in the radiological department of King George's Medical College,

It is difficult to define in a skiagram the point at which union may be said to be complete, but for our purpose an epiphysis was considered as definitely united only if the epiphysal space was, in bony architecture and density, indistinguishable from the epiphysis and diaphysis in its neighbourhood. Cases of recent union, where a thin line was still seen in the place of epiphysal cartilage, were classified as marginal cases.

We have divided the girls into eight age-groups of 10-11, 11-12, 12-13, 13-14, 14-15, 15-16, 16-17, and 17-18 years.

Summary of observations

Our observations can be tabulated as follows:—

Number showing union in each age group

	Years							
	10-11	11-12	12-13	13-14	14-15	15-16	16-17	17-18
Number of girls ..	17	7	6	18	21	19	17	20
Lower end of humerus	0	0	3	16	21	19	17	20
Medial epicondyle ..	0	0	3	14	19	19	17	20
Upper end of radius ..	0	0	0	10	18	19	17	20
Lower end of radius ..	0	0	0	0	3	9	10	13
Upper end of ulna ..	0	0	0	15	21	19	17	20
Lower end of ulna ..	0	0	0	0	5	9	10	13

Lucknow, at the suggestion of the second who was at one time reader in forensic medicine at the Lucknow University. The paper is complementary to that of Lall and Nat (1934).

The object of the investigation was to ascertain the ages of the union of epiphyses of Indian girls, as it is commonly believed that they unite at an earlier age than do those of European girls.

The skiagraphic method was thought to be preferable to the purely anatomical method of the study of the epiphysal union of long bones, as investigations could be carried out on a larger number of normal subjects whose ages were definitely known.

We had to face great difficulties in obtaining subjects for this work, on account of the *purdah* system, and also of the prejudices of parents. However, we managed to enlist the co-operation of three local girls' schools to supply the material, and we examined 125 girls of different communities, varying in age from 10 to 18 years. The total number of skiagrams taken was 250, both antero-posterior and lateral views being taken to make sure of the unions.

The figures given in the table do not, however, easily lend themselves to generalization about the union of epiphyses, but, taking the age group of maximum increase in percentage of union and the youngest age group showing union of 90 per cent or over as criteria for our generalization, we may summarize the results of this investigation as follows:—

1. Lower end of humerus.

Union takes place before the age of 15 years.

Considering the high percentage of union (90 per cent) one is justified in stating that union takes place mostly early in the 13-14 age group, that is, about the end of the 13th and the beginning of the 14th year.

2. Medial epicondyle. Unites at 15 years.

3. Upper end of radius. Unites at 16 years.

4. Upper end of ulna. Unites at 15 years.

5. Lower end of radius and ulna. Unites at 19 years.

These results are at least about two years ahead of the figures given in various European textbooks of anatomy, and about a year ahead of the comparative figures obtained for Indian boys by previous research, carried out in this department (Lall and Nat, 1934).

Simultaneously, with the above radiological observations, we recorded the following data on the eruption of the teeth and onset of menstruation on the same cases. The results can be tabulated as follows :—

Age in years	Number of teeth erupted	Age in years	Number of teeth erupted
10-11	24-26	15-16	28-29
11-12	26-28	16-17	28-30
12-13	28	17-18	30-31
13-14			
14-15			

Out of the total number of 125 cases examined, 73 gave a history of the onset of menstruation as shown in the following table :—

Number of girls	Age of the onset of menses	Number of girls	Age of the onset of menses
6	11	17	14
13	12	9	15
27	13	1	16

From the above table we came to the conclusion that the menstruation starts in the majority of Indian girls between the ages of 12-14 years, and we also noticed that most of the girls examined showed signs of maturity at the age of 13 years.

Discussion

The calculation of age by radiography is not as accurate a science as lawyers and some doctors seem to think. What we are striving at is to get an approximate age for Indian girls from skiagrams which, together with puberty, teeth and general appearance, will enable us to give more accurate evidence of age in court.

Table showing the ages in years when union at the elbow and wrist joints occurs amongst Europeans and Indians

Parts	European standards	Indian boys	Indian girls
Lower end of humerus	16-17	15-16	14-15
Medial epicondyle ..	18	17	15
Upper end of radius ..	17-18	17	16
Upper end of ulna ..	16	16	15
Lower end of radius ..	20	19	19
Lower end of ulna ..	20	19	19

In 1936 in conjunction with his assistant, Rai Sahib Dr. Bhandari, the second writer drew up a table, summarizing the work done to date in India as regards the elbow and wrist joints. These joints have been chosen because more detailed examination of other bones is beyond the finances of an ordinary hospital; and also the examination of these joints can be carried out without undressing the children. These are important considerations in such an investigation.

Since this table was prepared the only Indian work on the subject is on 'Bengali Girls' by Basu and Basu (1938). We have incorporated these in the table below. It will also be noted that we have left out the head of the ulna. In our opinion this is one of the most difficult epiphyses in which to judge union, and there is such divergence of opinion by all authors that we have not been able to place reliance on it.

With regard to comparative figures given for England and America, we have taken anatomy books and x-ray specialist books on fractures, which are generally accepted as standard works on the subject. All have been quoted in the various Indian articles on this subject.

THE TITRE OF COMPLEMENT IN A SAMPLE OF HOSPITAL POPULATION IN CALCUTTA

By R. K. GOYAL, D.Sc., Ph.D., M.R.C.P., F.R.S.E.
and

S. LAL, M.B., B.S.

(From the School of Tropical Medicine, Calcutta)

As there are no published records of the titre of complement in the blood of Indians, it was thought desirable to examine a series of apparently-healthy individuals. In this paper are recorded the results of the examination of 204 individuals of the type that attend a hospital out-patient department. The methods employed are summarized below. It was felt, however, that the estimation of complement without the determination of the hæmolysin present in the serum would give fallacious results and therefore hæmolysin present in each sample of serum was estimated.

Technique.—Three to four cubic centimetres of blood were drawn from the ante-cubital vein and kept in the incubator for 30 minutes, then left in ice-chest for three to four hours. The serum was separated, the complement titre and hæmolytic activity were then determined. A three per cent suspension of sheep cells and six

units of hæmolytic amboceptor were used. The test was put up as follows :—0.25 c.cm. of the serum under test, 0.25 c.cm. of the sheep-red-cell suspension and 0.5 c.cm. of normal saline. Sensitized red cells were used for the estimation of complement, the hæmolytic amboceptor was omitted in testing the hæmolytic property of the serum. The results were read after 30 minutes.

The complement titre was found to be equal to the hæmolytic titre in a certain percentage of cases, showing thus the absence of complementary activity of the serum as such. So the following calculation was adopted to determine the amount of complement as distinguished and free from normal hæmolysins. Complete lysis of red blood corpuscles with undiluted blood was taken as equivalent to one unit, a trace of lysis equalled 0.25 unit, partial lysis 0.5 unit and almost complete hæmolysis 0.75 unit. In this way, almost complete hæmolysis by 1 in 12 dilution of serum could be expressed as the serum containing 11.75 units. It was thus possible to deduct the hæmolytic figure from the complement figure and state the amount of corrected complement in a particular case.

In referring to the complement, we would mention data regarding corrected complement only unless otherwise stated.

(Continued from previous page)

Summary.—(1) In India, estimating the age of adolescents has only in the last few years been determined by x-raying epiphysial union.

(2) The subject, especially in females, has great medico-legal importance. No Indian medico-legal textbook has published any authoritative tables.

(3) Investigations at present published are confined to Bengalee and United Provinces girls.

(4) The number of cases examined so far are too few to generalize upon.

We can, however, say that the Indian girl is at least a year ahead of European girls in development between the ages of 10 and 20 as far as bony union is concerned.

We wish to thank the Lucknow University for placing at our disposal the means to carry out this work, and also Dr. A. P. Verma, who, as Kunwas Inderjit Singh's research scholar, has rendered valuable assistance.

We are hoping that this article will reach a wider circle of readers than the previous article in the *Indian Journal of Medical Research*. We apologize to any authors whose work on the subject has passed unnoticed.

TABLE

	Num- ber of cases	Percentage distribution						
		Negative	Dilutions					
			0	2	4	8	12	16
Complement	204	1.5	0.5	22.5	58	12.7	2.9	1.9
Hæmolysin	204	8.3	8.3	40	41	2.4

It will be seen from the table that titre of complement present in the blood of hospital class Indians is somewhat lower than the figure obtained in Europe and America. In a series of 204 Indians, the average amount of serum to produce complete lysis of sensitized red cells was 0.06 c.cm. (range between 0.0156 c.cm. to 0.33 c.cm.), 1.5 per cent cases had no complement (uncorrected) in 0.25 c.cm. of the serum. The average amount of corrected complement was 0.147 c.cm. with a range between 0.017 to 1 c.cm. in positive cases. No complement could be demonstrated in 0.25 c.cm. of undiluted serum in 40.7 per cent cases. Hadjopoulos and Burbank (1928) examined a series of two thousand apparently-normal Americans; the average hæmolytic complementary titre was found to be represented by 0.04 c.cm. of active serum. Veil and Buchholz (1932) found the complement titre of normal blood in central Europe to range between 0.02 c.cm. and 0.06 c.cm. with an average volume of 0.05 c.cm. A similar titre was found by Tilden (1935) in America. Sera from a small series of (seven) apparently-healthy middle-class Indians gave a

lower figure, i.e., an average volume of 0.08 c.cm. (42.8 per cent positive, average complement 1.46 units, limits 0—8 units). A study of the table will show that hæmolysin, as distinct from complement, is present in the sera of a large number of individuals.

A similar examination carried out in a small series (nine) of apparently-healthy Europeans living in Calcutta showed a high titre of complement (complement present in all, average units of complement 5.05, limits 0.5—16.0). A similar series (15) of Anglo-Indians had complement present in 60 per cent (average units of complement 2.0, limits 0—10.5).

Analysis was made as regards age, sex, diet and the complement titre of the series examined. As the figures in the various groups are not enough for statistical analysis much significance is not attached to the conclusions which are as under :—

The complement titre was the same in various age groups. It was less in females (18 examined, 33.3 per cent positive, average units 0.87, limits 0—3.5) than males (186 examined, 61.8 per cent positive, average units 1.77, limits 0—14). As regards diet, a greater concentration of complement was present in non-vegetarians (16 examined, 81.25 per cent positive, average units 2.7, limits 0—6.5) than in vegetarians (37 examined, 65 per cent positive, average units 1.4, limits 0—7.75).

Bengalees take an excess of rice, whilst the non-Bengalees generally take starch in the form of bread. No marked difference was found between these two classes of people (Bengalees 130, 62.3 per cent positive, average units 1.85, limits 0—11.5. Non-Bengalees 74, 54 per cent positive, average units 1.41, limits 0—13.5).

The constitution of the individual appeared to have no effect on the complement present in the blood; 61 individuals suffering from filariasis attending the out-patient department apparently in good health gave results similar to the healthy individuals (55.7 per cent showing complement, with an average of 1.54 units, limits 0—14). Eleven diabetics were examined, all showed considerable amount of complement (percentage showing complement being 81.8, average units of complement 6.7, limits 0—13.5). In this connection it would be of interest to point out that Hadjopoulos and Burbank (*loc. cit.*) also found a high complement titre in pathological conditions giving rise to high metabolism.

Summary

An examination of the sera of 204 Indians revealed complement titre of 0.147 c.cm. as distinguished and free from hæmolysin.

OBSERVATIONS ON SOME IMMUNOLOGICAL ASPECTS OF LEPTOSPIRAL INFECTIONS

PART II

By B. M. DAS GUPTA

(From the Department of Protozoology, School of Tropical Medicine, Calcutta)

IN a previous paper, we (Das Gupta, 1939) have noted that passive immunity can be induced in guinea-pigs following injections of anti-sera obtained from different sources, and the duration of the protection thus acquired is decidedly short and varies according to the nature of the anti-sera used.

This investigation was carried out to determine whether transference of passive immunity from the mother to the descendants does occur in leptospiral infection as in the case of some bacterial disease, such as diphtheria, and, if so, how long this congenital immunity would persist.

Method

Guinea-pigs were immunized either by inoculations of increasing doses of formalized cultures or by a single dose of 2 c.cm. of rich live culture followed 24 hours after by 0.25 c.cm. of immune rabbit serum given intraperitoneally. The latter procedure was found to be a very efficient and quick method of immunizing guinea-pigs against leptospiral infection. The sera of these animals agglutinated the homologous strain in a dilution of 1 : 10,000 in every case. This titre had not decreased till the 192nd day after the inoculation, when the sera were last examined. Besides, these sera showed well-marked protective power against infective inoculations—0.1 c.cm. protected guinea-pigs against 2 c.cm. of virulent culture. Animals of the same weight (serving as controls) which received 0.1 c.cm. of normal rabbit serum before the infective inoculation succumbed to leptospiral infection in from 7 to 10 days.

Five well-nourished adult immunized females were caged with full-grown males. After a period varying from 78 to 94 days these females gave birth to 3, 2, 3, 3 and 1 young ones, respectively. As the mother no. 4 killed all her young immediately after birth, the fourth litter could not be experimented on.

The gap between 62 and 188 days was purposely kept; for, the worker wanted to see whether congenital immunity would pass on to the second generation, although apparently unlikely. When the guinea-pig (a) of litter V was four months old it was caged with a male, but when it did not show any sign of pregnancy for six months it was given an infective inoculation lest its susceptibility to infection should have decreased with increasing age.

It was not possible to keep controls side by side for individual cases, but six guinea-pigs which were born of normal mothers and were

TABLE

Number of litters	Serial number of young ones in each litter	Time of inoculation with the infective material	Nature and dosage of infective material	REMARKS
I	(a)	Within 5 minutes of birth.	0.5 c.cm. of virulent culture	Remained alive and well for 3 weeks.*
	(b)	Within 30 minutes	Do.	Do.
	(c)	" 20 hours	Do.	Do.
II	(a)	On the 7th day of birth	1 c.cm.	Died two days after infective inoculation of some inter-current disease.
	(b)	" " 14th " " "	1 c.cm.	Remained well and alive for 3 weeks.
III	(a)	" " 28th " " "	1.5 c.cm. of liver emulsion of an infected guinea-pig containing innumerable leptospiræ.	Do.
	(b)	" " 45th " " "	1.5 c.cm. of virulent culture	Do.
	(c)	" " 62nd " " "	Do.	Do.
V	(a)	" " 188th " " "	2 c.cm. of virulent culture	Died of leptospiral infection on the 9th day of inoculation.

* Animals that remained alive and well for three weeks after the infective inoculation were considered to be protected against the infection.

of varying ages (20 hours, 4 days, 10 days, 32 days and 6 months respectively) were inoculated with the same strains and proved extremely susceptible to the infection, although the guinea-pig no. 6 of this control series showed an unusually long incubation period.

Remarks.—It will be seen from the foregoing table that young guinea-pigs born of immune mothers up to the age of 62 days remain insusceptible to infection with the homologous strain. This finding is significant because it shows that the use of guinea-pigs born of immunized mothers for diagnostic inoculations would lead to fallacious results because of their acquiring a considerable degree of refractoriness to the infection up to 2 months of their age, *i.e.*, the period when they are suitable for inoculations for purposes of diagnosis.

During our investigation into leptospirosis for the last two years, it has been our experience that a certain number of guinea-pigs inoculated with the infected material develop the disease but recover spontaneously. These animals acquire absolute immunity against further infection.

Summary

Young ones born of mothers (guinea-pigs) actively immune to leptospiral infection exhibit marked resistance against homologous infection. This resistance persists till the 62nd day after birth but not up to the 188th day. It is therefore suggested that the female guinea-pigs which have acquired immunity by some means or other

should not be used for breeding purposes as the young born of these animals are unsuitable for diagnostic inoculations.

A HOME-MADE 'TOMOSCOPE'*

By WILFRED G. JONES, B.Sc., M.D.

Medical Superintendent of the Wanless Tuberculosis Sanatorium, Wanlesswadi

and

E. W. BRADLEY-BOWRON

Manager

A TOMOSCOPE is an apparatus that takes an x-ray film of a narrow section of the body. Just as a book on anatomy shows relationships in a cross section, a sagittal section (an antero-posterior plane), or a lateral section, so a tomogram (the film made by a tomoscope) is an x-ray of a similar 'section' of the body. These tomogram sections are usually made in a lateral (side to side) plane; *e.g.*, in figure 1, we have a rough cross section of the chest at the level of the heart. A series of tomograms at sections A, B, C, D, and E would include most of the lung tissue, and any cavity, x, would be found, unless it was very small, as cavity y. If we know approximately where the cavity is, the tomograms may be taken close together as at D, G, and E. Usually, for

* Selected for special tuberculosis number but held over on account of lack of space.—Editor, *I. M. G.*

the sake of economy, the tomogram may be limited to a half or a quarter film, so the process is not expensive, as four such exposures are sufficient for most cases.

A sectional tomogram as described above is not a competitor of an ordinary postero-anterior x -ray film, but is extremely useful when the cavity is invisible on the flat film on account of obscuring densities, pneumonic consolidation, or overlapping bone shadows; or when the cavity is mistaken for a pneumothorax pocket, or is lost in a hilar shadow.

Fig. 1.—Cross section of the chest.

The original tomoscopes were developed in Germany, and are quite elaborate affairs, selling for Rs. 7,000 or so. To understand the principles involved we constructed a simple cardboard model, illustrated in figures 2 and 3. Two boards are connected together by a cross member HJ. On the larger board is drawn a diagram representing a cross section of the body. The smaller board represents a cassette holder. Lines projected from the x -ray tube A, through

Fig. 2.

Fig. 3.

- A .. x -ray tube.
- F .. Chair with adjustable sliding seat.
- G .. Stand for cassette holder.
- HJ .. Connecting rod between chair and cassette stand.

a point y in the body, fall on point y_1 on the cassette, and these two points remain in line (i.e., in focus) even when the boards are rotated about 90° to position in figure 3. Similarly, any other point on the focal plane BH will be in focus and hence clearly projected to the cassette and its film. This is not true of any other point in the body not in this focal plane, e.g., the point v which is projected to point 1 on the

cassettes in figure 2, and to point 2 in figure 3. The image will therefore not be a point but a blurred line. Similarly all other tissues not on the focal plane BH will be blurred as the body and cassette are rotated.

It will be noticed that the focal plane BH is fixed, as the anterior board rotates on the two fulcrums at F and H. But the focal plane may be set at any part of the body by merely placing the body diagram forward or backward on the board. In figures 2 and 3 the double outlines represent a chair seat with a body on it. A sliding adjustment of the seat on the board would give a flexible arrangement which is mechanically simple to reproduce.

The cardboard model which was made by one of us (E. B.) clearly demonstrated also that the lines of x -ray projection are not altered in the least whether the x -ray tube be moved through an arc while the body is stationary, or the tube be motionless and the chair and cassette be rotated as illustrated in figures 2 and 3. (In the first instance, when the x -ray tube is rotated, it is the tube and cassette that are coupled together to give synchronous motion.)

This demonstration settled for us the matter as to which method to employ in our home-made model. Rotation of the x -ray tube through an arc necessitated a shock-proof apparatus which we did not have, and entailed expense that we could not consider. In the German models the movement of the tube is from head to foot of the patient, i.e., perpendicular to the axis of the ribs. While this is theoretically correct we found out by actual practice that rotation of the chair parallel to the ribs did not seriously interfere with the demonstration of cavity shadows in our cheap machine.

Moreover the vertical position of the patient which is obtained in the model we have developed allows for the natural position of the lungs during tomography and clearly reveals levels of fluid in pulmonary cavities. This is of great value in locating cavity shadows, which at times is not easy.

Our machine is exceedingly simple. Two vertical axes (Ford front wheel axes) are set in a solid wooden base, about 16 inches apart. A chair is firmly fixed to the anterior axle. The chair seat with its back is set on two sliding bars mounted on the rotating base, and there is a pin arrangement to lock the seat firmly at any desired position relative to the fixed point—the axle which is the centre of the focal plane. On the right side of the chair base is a scale showing in centimetres points in front or behind the focal plane, which works in conjunction with a pointer on the sliding seat, and a corresponding scale on the chair back readily permits calculation of the focal plane in relation to the chest of the patient sitting in the chair.

On the rear axle is mounted a wooden frame to which the cassette holder is fixed, and which can be adjusted to the height of the patient. During exposure the cassette rotates in such a

way that it is always parallel to the focal plane of the chair. The wooden frame must be made of such materials that will not permit vibration of the cassette during the exposure of the film, whilst it is rotating. A connecting bar from chair base to cassette stand insures equal and simultaneous rotation of the two parts.

An x-ray tube is set in front of the patient approximately at a distance of four feet (see figure 4). The patient is rotated so that his

Fig. 4.—Tomoscope. Seat focus adjustment.

face is at an angle of 45° to the x-ray tube. On release of the catch the patient and the cassette rotate towards the x-ray tube about 90° by means of a series of opposing springs that are put under tension by the rotation. While they are so rotating an x-ray exposure of approximately $\frac{3}{4}$ to 1 second is made. At 100 MA the KVP is about 10 volts more than for an ordinary x-ray exposure at the same distance. The cost of this machine was Rs. 50.

The number of exposures that will be necessary in any case depend on the estimated size

of the cavities to be located. From four to six exposures 1.5 to 2.0 cm. apart are usually sufficient, though we have taken as many as nine at a 1-cm. interval in two cases.

In the following section we give a number of examples of cases showing definite cavities. Equally important, however, is the fact that we have found the value of a negative result also very great. We can rely on the absence of cavities of any appreciable size in such negative cases, and therefore have an assurance that collapse therapy is not imperative for closure of cavities but simpler measures may be sufficient.

Case 1.—Male, aged 30, admitted with a left pneumothorax, tuberculous empyema and an adherent apex (figure 5). The right side showed diffuse involvement also. The general condition of the patient was poor.

Figure 6 shows the true condition of the left apex, and explains why the pneumothorax was not effective in curing the patient. He should never have had continuance of the pneumothorax but thoracoplasty to close the cavity before empyema and contralateral spread made any treatment impossible.

Case 2.—Enid, age 20. Figure 7 shows the large amount of bilateral disease present on admission. Figure 8 taken nearly one year later shows an almost complete pneumothorax, but the sputum remained positive.

Several tomograms of the right apex had failed to show any cavities. But a tomogram of the left apex (figure 9) taken a little later shows an unsuspected buried cavity.

The pneumothorax was therefore abandoned and thoracoplasty done (figure 10). The disease on the right side cleared away spontaneously. The cavity is now closed, the sputum persistently negative, and the case discharged as apparently arrested.

Conclusion.—1. Tomography in chest surgery is very helpful in locating cavities not visible in the ordinary flat film.

2. A simple tomoscope can be constructed at low cost and it functions quite efficiently.

A Mirror of Hospital Practice

NOTES ON CASES OF PHTHISIS TREATED WITH PARENTERAL GOLD

By S. K. DAS, M.B. (Cal.)

Visiting Physician, Islamia Hospital, Calcutta

Case 1.—Moderately advanced bilateral lesion treated with gold alone.

A European male, aged 20, stated he had been treated in Rangoon with sanoerysin, calcium, and later solganol. He gave a history of hæmoptysis, sometimes profuse, for the past 18 months, and he had a dry cough with a slight evening rise of temperature for the past six months. His appetite and digestion were good and he complained of dyspnoea and palpitation on exertion.

The man was very emaciated and weighed 8 st. 13 lb. He had crepitations on the upper zones of the lungs on both sides, more on the left and there was congestion of the throat.

He was placed on 'home sanatorium' regime and a total of 3.2 gm. of myocrysin was given at weekly

intervals in accordance with the dosage table given in the *Indian Medical Gazette*, 1939, Vol. LXXIV, p. 328. The urine remained free from albumin throughout.

The result of treatment was a gain of 9 lb. in weight; sputum and cough stopped; hæmoptysis stopped; temperature remained normal; dyspnoea and palpitation with moderate exercise disappeared; the vital capacity remained and the sedimentation rate of the red cells fell from 68 to 8.

X-ray plates taken before (figure 1), and after (figure 2) treatment showed concentration of the lesions with formation of dense productive infiltration on both sides.

Case 2.—Moderately advanced bilateral lesion treated by phrenic evulsion on the more active side and gold therapy.

The patient was a Hindu male, aged 25 years. He had a troublesome cough and a large amount of expectoration. Hæmoptysis which began about a year ago was profuse. He had a continuous temperature ranging between 99.5°F . in the morning and 101.5°F .

Case 5. Fig. 2.

in the evening. His appetite and digestion were bad. He complained of palpitation and dyspnoea even at rest and had pain on both sides of the chest. He was very emaciated. He had syphilis and gonorrhoea six years previously.

The man's weight was 6 st. 4 lb. There were crepitant râles on both sides of the upper part of the chest and signs of cavitation on the right. The urine contained a trace of albumin, casts and red blood cells. The x-ray showed soft infiltration of the upper and middle zones with a cavity on the right, there were scattered small foci in both bases.

Four inches of the right phrenic nerve was removed and this was followed for a few days by an enormous amount of purulent sputum and a high febrile reaction. After complete rest the temperature became lower but was never normal. Twenty-four c.cm. of 25 per cent glucose solution was given intravenously and 10 units of insulin hypodermically for three days and the albumin and casts disappeared. The first two doses (see table) of myocrysin in oil were given without any bad effect on the kidneys. The temperature fell a little, the appetite improved, the sputum became thin and scanty and contained much fewer bacilli. A few crepitations were still present on the right side.

The patient was now considered fit for sanatorium treatment in a cooler climate so he was sent away from Calcutta and is now living in the hills. He is afebrile, can take moderate exercise and has gained 9 lb. in two months. X-ray plates are not available.

Case 3.—Artificial pneumothorax combined with gold treatment with apparently more rapid improvement than with artificial pneumothorax alone.

The patient was a Hindu female, aged 28 years. A 4 para. Her mother died of tuberculosis three months ago.

She had had a dry cough for three months and profuse hæmoptysis. X-ray examination showed soft infiltration in the left sub-apical and middle zones. Left-sided artificial pneumothorax was performed and after four refills crisalbin in glucose solution was administered intravenously and a total of 2.8 grammes was injected. Eighteen months later x-ray showed the lesion in the middle zones as a simple scar and the sub-apical one had disappeared.

The patient is living an active life and has gained 2 stones in weight.

Case 4.—Early lesion of moderate severity; given artificial pneumothorax which was followed by usual complications.

A Hindu male, a student, aged 20 years. Has a slight cough and had a moderate hæmoptysis 15 days previously. Complained of weakness and loss of weight. A skiagram (figure 1) showed soft infiltration in the right upper zone and to a less extent in the middle zone. The left lung was normal. He weighed 6 st. 12 lb. Artificial pneumothorax was induced and was carried on for nearly three months and all symptoms showed abatement. An x-ray (figure 2) taken at this time showed beautiful selective collapse but there was a little fluid at the base. Treatment was continued and four weeks later the patient had a continuous high temperature for four days with pain on the right side and cough. There was succussion splash on the right side and dullness up to the fourth rib. Clear serous fluid was found on exploration and some of it was removed, but complete evacuation was not possible as it was in separate pockets. Calcium and diuretics were prescribed and some of the fluid was absorbed. Artificial pneumothorax was abandoned on account of adhesions. Gold therapy was advised but could not then be undertaken. An x-ray (figure 3) a month after this attack showed the right chest to be filled with fluid up to the second rib and there was an early infiltration in the left sub-apical area.

Myocrysin injections were begun and are still being given. The patient is now symptom free. A skiagram

(figure 4) shows great improvement, the fluid is absorbed and the lesions show definite productive reaction and the weight is now 7 st. 8 lb.

Case 5.—Unilateral lesion with failure of artificial pneumothorax and phrenic evulsion performed later.

A Hindu female, aged 22 years—primipara. Complained of cough for six months with scanty expectoration. Epistaxis (? hæmoptysis) six months ago. Appetite bad, digestion good but says she is subject to vomiting, bowels regular. Had a left pleural effusion about five years ago treated by removal of fluid and gas replacement, and had dysentery about the same time.

The patient weighs 77 lb. Wassermann reaction doubtful. There is amphoric breathing in the left sub-apical region and crepitations in the right middle zone. A skiagram (figure 1) showed soft infiltration in the right apical and sub-apical regions and patchy infiltration in the lower zones and a very small patch in the left sub-apical region. Pleural thickening of both bases and small calcified spots on the left side.

Artificial pneumothorax on the right side was induced but failed so $3\frac{1}{2}$ inches of the right phrenic nerve was removed. Intravenous treatment with crisalbin was begun five weeks later. The patient had an attack of malaria during this treatment which was treated with atabrin. A total of 2.75 grammes of crisalbin in glucose was injected according to the dosage given in the table (*Indian Medical Gazette*, 1939, Vol. LXXIV, p. 327.)

The patient is steadily improving, she is gaining in weight, has no symptoms, her temperature is normal and she can take a moderate amount of exercise. A second x-ray plate (figure 2) shows disappearance of the infiltration and formation of scar tissue.

HYDATID DISEASE OF THE LUNGS

A CASE REPORT

By R. N. CHOPRA, C.I.E., M.A., M.D., Sc.D. (Cantab.),
F.R.C.P. (Lond.)

BRIVET-COLONEL, I.M.S.

C. L. PASRICHA

MAJOR, I.M.S.

and

S. LAL, M.B., B.S.

(From the School of Tropical Medicine, Calcutta)

MAPLESTONE (1933) after reviewing the recorded cases of hydatid infection in India suggests that there is a strong probability that the incidence of hydatid disease is commoner in India than the records in the medical literature indicate. Sami (1938) drew attention to the relatively high incidence of hydatid disease in certain rural areas in the Punjab. This author records 27 cases of hydatid infection proven by operation and 13 others in which a clinical diagnosis of hydatid infection was made but operation was refused. These patients were seen in the course of six years and the *Indian Medical Gazette* (Editorial, 1938) commenting on this report stresses that these figures probably only represent a fraction of the actual cases that really exist in the area. A search through the published records in India reveals only two recorded cases of hydatid cysts of the lungs, Tulsi Dass and Prithi Chand (1934) and Ukil (1937). The following patient was brought to one of us for opinion with a history of long-standing lung trouble and with a knowledge of

the existence for years of a hydatid cyst of the lung which had been confirmed by x-ray photograph. As the condition is comparatively rare in medical literature in India it was thought advisable to record this case.

Case record

The patient, a middle-class Bengalee Hindu male, 38 years of age, resident of the district of Hooghly, gave a history of general ill health for the past 12 years and that 10 years ago after being under suspicion for some time as a tuberculous patient x-ray examination revealed the presence of a dense mass in the left apical region which was thought to be a hydatid cyst. His general health had been fair and he had not suffered at any time from marked pulmonary symptoms. Three months prior to being seen in November 1938 the patient had rigors almost daily and had suffered from pain in the right side of the chest. He was admitted to the Carmichael Hospital for Tropical Diseases for further investigation.

On physical examination there was an area of dullness and absence of breath sounds in the left upper lobe. Liver was enlarged to the umbilicus but showed no irregularities of the surface or the border. The spleen was just palpable. There was moderate degree of hypochromic anaemia and the differential count was within normal limits with 3 per cent eosinophil cells. Sedimentation rate was increased and was 25 mm. in the first hour and 110 mm. in the second hour with a cell volume of 34.3 per cent. Nothing else abnormal was noted. Antero-posterior and lateral skiagrams showed a large circular opacity in the upper zone of the left lung. When seen stereoscopically this opacity appeared to be globular in shape and the size of a small coconut. The lung tissue at the lower and inner margin appeared to be compressed. There was no evidence of a cyst in the liver or the spleen, both of which were enlarged and denser than normal. When compared with the skiagram taken ten years previously the shadow now is denser and about one inch larger in diameter. There is no infiltration of the lung tissue, which appears to be pushed aside. The characteristic clear-cut sharply-defined outline of the cyst is well seen.

The intradermal test of Casoni gave a well-marked reaction. The fluid used for this test had been obtained three days previously from a hydatid cyst removed by operation from the mesentery of a patient. This fluid injected into healthy individuals gave no reaction.

During his stay in the hospital the patient had rigors almost daily with rise of temperature to 102 or 103°F. Repeated examinations of the blood showed no malarial parasites. The rigors were brought under control by a course of atabrin, after which the patient improved in general health.

LYMPHO-SARCOMA OF ILEUM

By A. E. STEVENS, F.R.C.S.D.

Chief Medical Officer, The Salvation Army, Thomas Emery Hospital, Moradabad, U. P.

THE rarity of this condition prompts the publication of this report.

The patient was an Indian male, aged 24 years, unemployed. Admitted to hospital 7th April, 1939.

History.—Pain in the abdomen for three months, usually all over, but often worse on the right side. Frequent attacks, lasting about 24 hours. Occasional vomiting. Appetite poor. No loss of weight noticed. No cough. No fever. Bowels constipated. No urinary symptoms.

Past history.—No serious illness.

Examination.—Healthy looking man. Tongue clean. Abdomen—Small tumour, size of an egg palpable just below and to the right of the umbilicus. Easily movable but tender to touch. No rigidity of muscles. Liver and spleen not felt. Heart and lungs normal.

Laboratory findings.—Blood—Haemoglobin 55 per cent. Red blood corpuscles 2,384,000. Total leucocytes 10,200. Polymorphs 72 per cent. Lymphocytes 21 per cent. Large mononuclears 2 per cent. Eosinophiles 2 per cent. Myeloblasts 3 per cent. Malaria parasites not seen. Kahn test negative. Urine normal. Stools normal.

10th April, 1939.—Laparotomy performed. Growth found in the ileum about two feet from the ileo-caecal junction. Two glands present in mesentery. Excision of growth and glands with one foot of intestine. Intestinal anastomosis. Other abdominal viscera appeared normal.

Convalescence was satisfactory though he suffered from a little post-operative diarrhoea.

1st May, 1939.—Discharged from hospital. Wound healed. No pain. Bowels acting normally. Appetite improving.

Patient was seen on 21st June, 1939, when he had started to gain weight, his bowels were acting normally, and his general condition was very good.

Pathological findings.—Macroscopically the growth was a white homogeneous sessile mass 1½ inches long by 1 inch wide, projecting into the intestine for about half an inch. There was no ulceration. The glands were of a homogeneous consistency and rather white.

Microscopic report.—Lymphosarcoma with metastases in the lymphatic glands.

Comment.—Most cases of sarcoma of the small intestine are reported from the post-mortem room, as they have manifested themselves by their secondary deposits. This case presented itself in the early stage before there was gross glandular involvement, and so was amenable to total eradication.

I am indebted to Dr. Hameed, Provincial Pathologist to the United Provinces, for the pathological report of this case.

Indian Medical Gazette

OCTOBER

THE QUININE FRAUD

THE pages of the *Indian Medical Gazette* have often been the scene of the struggle between the champions of two methods of quinine administration, the oral and the intramuscular. In these discussions, we have, at any rate during the last decade, kept an open mind, but with a slight prejudice in favour of the supporters of the oral method which we believe is the method of choice in ninety-nine cases out of a hundred. It is not our intention to revive this controversy.

Sir John Megaw, a former editor of this journal, analysed the reasons for the failure, or apparent failure, of quinine by mouth, and one of the first reasons he gave was the absence of quinine from the mixture which was supposed to contain it. He collected samples of so-labelled quinine mixture from a large number of government dispensaries from all over India and tested them for their quinine content; he found that the vast majority were under strength, that many samples contained no quinine or other cinchona alkaloid, and that in many more the quinine was reduced to a dose which would be ineffectual in controlling malaria in patients to whom it was given. In such circumstances, it is not surprising that failures of oral quinine are frequently reported and that intramuscular quinine which is given in the form of a sterile solution made from specially prepared, often proprietary, tablets gains favour.

It was at least thirty years ago that Sir John started this campaign against under-strength quinine mixtures, and the subject was again revived by the Drugs Enquiry Committee under Colonel R. N. Chopra in 1931. They found a similar state of affairs and used this evidence to strengthen their recommendations regarding the legislative control of the drug trade, and of the profession of pharmacy. Not many of the excellent recommendations of this committee have yet been put into operation, but a beginning has been made by the establishment of a Drug Standardization Laboratory at the All-India Institute of Hygiene and Public Health in Calcutta. Elsewhere in this number will be found a paper from this laboratory reporting their experience in connection with quinine and cinchona alkaloid mixtures and tablets, collected from dispensaries and also purchased in the open market. Their findings show that this quinine fraud—one can call it nothing less—is still being practised widely, not only in government and other charitable dispensaries, but on the purchasing public.

Of the 100 samples of quinine mixture examined, 64 were below strength; of these, two

samples contained no quinine or other cinchona alkaloid, 13 less than 30 per cent of the amount claimed and 25 less than 60 per cent. The quinine tablets were little better, as 22.5 per cent contained less than 60 per cent of the amount claimed on the label. Tablets of Indian and foreign origin were equally represented amongst the deficient samples, but, of the quinine salts and cinchona febrifuge powders tested, 62.5 per cent of the Indian samples were below strength.

It is hard to believe that those who refuse to take any measures to remedy such a state of affairs and who repeatedly shelve legislation directed towards the proper control of the drug trade can appreciate the significance of some of these findings. Malaria is a common disease in this country, but it is also a very fatal disease. Malarial attacks vary in their seriousness, and we all know perfectly well that in the large majority of cases, even if no drug is taken, the fever will last a few days and then subside, but we also know that there are heavy malignant tertian infections, with numerous parasites to be seen in every field of the blood film, in which immediate treatment is necessary to save the life of the patient; if in such a case the 'quinine' which is given is not quinine at all, but bicarbonate of soda or some inert substance—as was the case in several of the samples tested by Dr. Bose and his co-workers—that patient will almost certainly die. The man who withheld the quinine from that tablet or mixture or who allowed it to be labelled 'quinine' when he knew that it was not quinine was as surely the murderer of that unfortunate patient as he would be had he thrust a knife into his back; the accessories are the doctors who did not see that the quinine came from a 'reliable source' and the authorities who make no effort to ensure that every source available to the public is a 'reliable source'.

Surely, if it was possible, as in the recent emergency, to take strong punitive action against the opportunist profiteers, it should be possible to take action against this chronic and deadly form of profiteering. The police do not wait for the murderer to strike; they arrest him as a suspicious character for carrying a knife. Similarly treated, the purveyor of quinine-less 'quinine' tablets would find it much more difficult to establish his innocence than would his fellow suspect with the knife.

That some of the deficiencies of quinine in the mixtures is due to carelessness and not all to dishonesty is shown by the fact that 16 samples were actually over strength, some to a dangerous degree. Carelessness in a dispenser is however as great a crime as dishonesty and this only emphasizes the need for legislation to control the profession of pharmacy.

The Government of India have shifted the responsibility on to the provinces; will not some of the more progressive provincial governments

shoulder this responsibility and rise to the emergency—as an emergency it must be con-

sidered—in the way they have done so admirably in the recent national emergency?

Special Article

A NOTE ON THE MEDICAL ETHNOLOGY OF TUBERCULOSIS IN THE HILLS AND FRONTIER TRACTS OF ASSAM

By E. S. PHIPSON, C.I.L., D.S.O., M.D., F.R.C.P.

COLONEL, I.M.S.

Inspector-General of Civil Hospitals, Assam

INTRODUCTION

IN attempting to introduce, for the first time, among primitive oriental peoples, a concept of tuberculosis based on scientific truth, the acceptance of which, even in the western world, is little more than fifty years old, it is plainly of interest, and of some importance, to endeavour to ascertain the nature of the beliefs regarding tuberculosis which are actually current among the primitive tribes themselves.

Perhaps the most important single point to discover in such an enquiry is whether or not the disease, which is well recognized among all the principal tribes of Assam, is, apart from all the extraneous trappings of superstition and ignorance, recognized as communicable from one person to another. It is upon this one basic fact, more perhaps than upon any other, that every rational scheme for limiting the ravages of the disease must necessarily be founded, and if it can be established that this single concept of the disease is embodied in, or at least not obviously at variance with, tribal beliefs, there is at once some ground in common and a foundation on which it may be found possible to build.

The population of Assam, according to the 1931 census, is about 9½ millions; of these about one million are classified in the *Census Report* as tribal, i.e., 'persons who still worship their tribal deities in their own fashion'. The tribal inhabitants of Assam naturally preponderate in the hilly and mountainous regions which constitute more than half the area of the province, though they are represented in every administrative district, as shown approximately in the following table, abstracted from the 1931 *Census Report* (Chap. XII—Appx. ii).

District	Tribal inhabitants
Goalpara	89,000
Kamrup	20,000
Darrang	44,000
Nowgong	53,000
Sibsagar	32,000
Lakhimpur	15,000
Balipara Frontier Tract ..	1,000
Garó Hills	137,000
Khasi and Jaintia Hills ..	201,000
Naga Hills	148,000
North Cachar Hills	5,000
Lushai Hills	60,000
Sylhet	4,000
Cachar Plains	5,000
Sadiya Frontier Tract ..	23,000
(Manipur State)	155,000
APPROXIMATE TOTAL ..	992,000

The problems, therefore, towards the solution of which the present enquiry was directed, concern a group of inhabitants who comprise nearly one-ninth of the population of Assam but who may be said to inhabit an area equivalent to over half the total area of the province, and on these grounds alone deserve and require special study.

Apart from a very limited personal acquaintance with the medical ethnology of hill tribes in Assam, the data on which this brief study is principally based, were forthcoming as the result of an enquiry which the writer instituted among the officers administering the areas included in the Khasi and Jaintia Hills, the Naga Hills, the Hills of Northern Cachar, the State of Manipur, the Sadiya Frontier Tract, the Balipara Frontier Tract, the Garó Hills and the Lushai Hills; and the writer is greatly indebted to these administrative officers for collecting and placing local information at my disposal.

The principal object, then, of this enquiry was to ascertain if, and to what extent, the basic principles of the management of tuberculosis could be grafted on to or interpolated between tribal beliefs, so as to avoid any serious clash between scientific truth and tribal superstition. On the whole the result of the enquiry may be regarded as fairly favourable.

THE SCOPE AND NATURE OF THE ENQUIRY

The original enquiry, the scope of which was afterwards extended, had particular reference to the Naga tribes, and an outline of the propaganda was devised, and simple measures designed to meet the requirements of the Naga and similar tribes were circulated for opinion among the officers responsible for the administration of the various areas indicated above. The proposals circulated were as follows:—

A. Simple propaganda

(1) That the spread of the disease from one member of the family to the other is by means of the sputum which the sufferer spits on the floor of his house and which, after it has dried, is mixed with the dust of the house, and when stirred up by wind or by sweeping, rises into the air and is inhaled by other members of the family who are then liable to contract the disease, and that even the act of coughing, apart from spitting, infects the ground with some of the dangerous material.

(2) That the sputum, which is full of minute 'flies' only visible under a 'hospital telescope', and which is coughed up by the sufferer on to the floor of the house, particularly in the dark inner rooms of a tribal house, remains dangerous

for weeks or months but its power for causing harm can be abolished by the action of the sun and still more rapidly by fire, and for this reason, when a sufferer spits on ground outside a house and the sputum is exposed to many hours of sunlight it is not likely to infect anyone else, but it is extremely dangerous on the floor of an inner room of a house where sunlight never penetrates.

(3) That if the sputum of the sufferer is collected in a special vessel and the contents poured into the ashes of the family fire every day and the fire built over the ashes the poison will be destroyed and cannot harm any one.

(4) That if healthy members of the family live in the same room as a sufferer they are much more likely to contract the disease than if they live and sleep in another room of the same house. This is because the sufferer spreads the disease by coughing and sneezing as well as spitting. If, therefore, the sufferer has a room to himself the rest of the family are likely to escape the disease altogether, particularly if the sputum is collected and burnt as described above.

(5) That if, in addition to the provision of a separate room for the sufferer at the back of the house, the roof can be extended backwards or sideways covering a small open verandah connected with the back room of the house where the sufferer can spend most of the day in the open air but protected from the weather, not only will the rest of the family be much safer but it will be of great value to the sufferer himself.

(6) That in the larger villages, where there may be several cases of phthisis in different families, much good would be done by the building of a *basha*, or shed, of a suitable size with at least one open side and containing *machangs* or beds, where the sick persons can remain during the day, having their food brought to them and returning to their houses at night, or they could eat their morning meal in their own room in the house and probably the evening meal too. The reason for this is that the patient himself is much better in the open air provided that he is protected from the weather, and that at least during the daylight hours members of his family are protected from any close contact with him which might spread the disease.

B. Preventive measures proposed

The propaganda detailed above was intended to furnish intelligible reasons for the actual measures to be adopted, which may be summarized as follows :—

(1) *Provision, free of cost, of specially designed spittoons* of a simple and distinctive character, if possible in brightly coloured glazed earthenware and provided with a loosely-fitting lid secured by a piece of cord. This spittoon could, of course, be made of other material such as brass or other metal, but its shape and character should be such that it is not likely to be used

for any other purpose. A stock of these spittoons might be kept in district and sub-divisional headquarters and in outlying dispensaries and issued as required on application by the *gaon-buras*, and in schools by the *pandits* or schoolmasters, or by chiefs who would be instructed to see that every household in which there is a sufferer is provided with one, to be replaced as required, and the family instructed how to use it.

(2) Home segregation of the patient

There can be no doubt that the method of segregation within the family itself, provided it is of a nature which would be accepted by the people, would have an important effect in reducing the spread of the disease and the type of partial segregation indicated in A(4) above might have a good prospect of gradually being accepted by the people themselves and recognized as a regular means of dealing with the disease.

(3) Some simple form of open-air treatment for the patient

The construction of the usual tribal house is such that in many cases the small verandah extension referred to in A(5) above could be added at a very little cost, as building materials are everywhere cheap, and, as stated, would have the double advantage of improving the patient's chances of recovery to a substantial degree and of protecting the other members of the family.

(4) Provision of communal segregation for larger villages

In the larger villages, containing a hundred or more houses, it is quite likely that there may be more than one house containing a sufferer from the disease, and in such cases the provision of a specially made open-sided *basha* as described in A(6) is likely to prove of considerable value. The communal *basha* could be in the village itself, if the nature of the ground permits, and need not, and should not, be at any great distance from it, with the object both of reducing the difficulty of sending food to the sufferer and of preventing the growth of any idea that the sufferers are outcasts, who have to be segregated in the same way that lepers are segregated. It is important to prevent any such idea developing among a primitive people who are quite familiar with the disease and who have hitherto attended the sufferer in his own home.

RESULTS OF THE ENQUIRY AMONG THE DIFFERENT TRIBES

I. Tribes of the Naga Hills

Phthisis is a complaint well known among Nagas and its prominent symptoms of cough, fever, loss of weight and spitting of blood are recognized as those of a definite disease which is capable of spreading from a sufferer to other members of the family. It is regarded as a disease which, once contracted, is, sooner or later, always fatal and the idea of a possible

cure does not appear to enter their minds. They believe that the disease has become more prevalent in recent years than it used to be, and they would welcome any practical means of reducing its ravages. In view of their experience of the fatal nature of the disease, when once contracted, they have no doubt that any efforts to deal with it should be in the direction of prevention in which they, in their own interests, are quite willing to co-operate.

The first development of the disease in any particular family and, to a lesser extent, the spread of the disease in that family after one member has been infected, is usually bound up in some way with tribal beliefs. Thus the *Kukis* regard it as the result of the accumulated sins of one's ancestors being too heavy for one man to carry. They do not expect it to appear in every generation but they say it continues in families. The tribal cure for this disease, which is not always effectual, is by doing certain *gennas* in killing dogs.

The *Western Rengmas* assign no particular reason for contracting the disease, which they call *kenghye*, but they have a cure for it, by administering with water a powder made from pounding the dried bodies of the flying lizard (*tsengonyaizhu*). It is significant that *Rengmas* will not drink or eat from the vessels used by sufferers from the disease.

The *Eastern Angamis* believe that the disease is contracted by brave or wealthy men, who eat flesh, fish, fowl or vegetables which are taboo.

The *Semas* believe that the killing of some other person's live-stock will be punished by the development of the disease, but it may be cured by drinking that person's water and be yours.

The *Southern Sangtams* believe that one can give the disease to one's enemy by giving him earth from a grave to eat.

Among the *Lhotas* the disease is regarded as the operation of a family curse which is the penalty of entering the house of a family or tribe formerly, or still, at enmity with the tribe or family of the person entering the house, who will eventually develop phthisis as a penalty for his imprudence. The supernatural reason assigned for the first case in the family does not hold to the same extent with later cases occurring in the family, except in the limited sense that though later cases may be the result of the operation of the curse, the rest of the family do not necessarily adopt a resigned and fatalistic attitude, but, on the contrary, would be quite willing, and even anxious, to adopt any measures that can be taught them to avoid contracting the disease, and moreover the idea of defeating the operation of the curse in other members of the family is one which appeals to them, not only as being worth doing for their own sakes but as evidence that the curse is lifting and is not so powerful as it was believed to be, the family honour being therefore proportionately enhanced.

The way is thus open for the introduction of simple measures designed to limit the spread of

the disease, and, as these in themselves do not appear to run counter to any tribal customs, there appears to be no reason why they should not be freely accepted and adopted, perhaps even with some degree of enthusiasm, as affording a means of defeating the operation of the family curse, or whatever other cause is believed to be operating.

II. Tribes of the Khasi and Jaintia Hills

These tribes are, generally speaking, in closer touch with civilizing influences, and both the propaganda and actual measures would be likely to be effective with the co-operation of the missions and school teachers.

As regards the *Khasis* of old, it is a remarkable fact, which I have on the authority of Dr. H. Lyngdoh of Jowai, whose specialized knowledge has been of great value in the preparation of this portion of this note, that the *Khasis* in the early days had no knowledge of any disease prevalent among them presenting the symptom-group cough, emaciation and spitting of blood, and that, unlike most of the hill tribes in Assam, had in consequence no ancient name for it.

The existing name for the disease among *Khasis* is *pang swai* (debilitating disease) or *bampong tor* (ulceration of the lungs). These names and a certain knowledge of the disease itself, have arisen only in the last thirty years or so, since their contact with western civilization—and no doubt to a large extent as a result of it, and there is a very good reason to believe that when they first began to contract the disease and had no natural or acquired immunity, the disease ran, and indeed still runs, a more rapid and virulent course, in much the same way as the introduction of measles into the virgin soil of the South Sea Islands in the last century led to an epidemic of exceptional severity attended with a high mortality.

In view of the ignorance, until recent years, among the *Khasis* of any disease presenting the symptoms of pulmonary tuberculosis, which is easily recognizable as a definite disease no matter what cause may be assigned to it, it is of particular interest to record that among the *Syntengs* (inhabitants of the Jaintia Hills) a disease having the symptoms of cough, increasing emaciation and spitting of blood, has been known to exist in their tribe from the earliest days. It is called by the *Syntengs* *pang kymbat* (*pang* meaning 'illness' and *kymbat* 'drug' or 'poison', or, perhaps, 'virus'). The name does not appear to indicate that a person suffers from the disease only after he has been drugged or poisoned, but it is believed that there are certain families in the tribe that possess some mysterious power of communicating the disease to others, and that persons who eat or drink in the houses of such families or take food touched by members of these families are likely to suffer from the disease. People, therefore, shun these suspected families and will avoid eating and

drinking in their houses or taking food that they have touched. The idea underlying these beliefs is clearly that the disease is communicable from one person to another.

The Wars (inhabitants of the southern slopes of Khasi and Jaintia Hills) have similar beliefs. They call the disease *krah* or *ai bih* which mean 'poisoned'.

It seems likely, therefore, that among the tribes of the Khasi and Jaintia Hills there is a reasonable prospect of some success attending the introduction of preventive and possibly curative measures based on the modern conception of the disease.

III. Tribes of the Garo Hills

Phthisis is known to the Garos as *gitok asi nanga*. It is not regarded as a common disease among those living in the hills, but is recognized as more frequent in the plains, and especially among the Nepali settlers in the hills, particularly those engaged with milk trade; the older Garos do not regard the disease as very contagious or dangerous to others, but look upon it as a curse on the family of a murderer for having taken food or drink with the family of the murdered person without making some peaceful compromise beforehand. It is generally considered that once the disease is contracted no cure is possible, but the idea of preventive measures would have to be instilled by careful propaganda.

IV. Tribes of the administered area of the Balipara Frontier Tract

The tribal elements in this area are scanty, and consist of Yanno Dafflas, Miris and Garos to the number of about 1,200. No information is available from the tribes in the unadministered area.

V. Tribes of the Sadiya Frontier Tract

The principal tribes are the Abors and Mishmis; and tuberculosis is well known to both. Examples of tribal beliefs in connection with tuberculosis are those of certain Abor tribes which follow.

Beliefs held by Abors.—The Pasis and Minyongs and Padams attribute tuberculosis to having incurred the displeasure of either of the spirit *doying-angong* who lives in the clouds, and *siking-kedeng* who lives on the earth. (These two are husband and wife, and may also cause other illnesses as well, but only serious ones.) The displeasure is invariably incurred by not having carried out a pujah correctly. Two of the more important pujahs are given below, failure to carry them out correctly being considered to invite a visitation of the disease: (i) *Abgang* (the pujah after hunting), (ii) *Mopun* (the pujah specially devoted to the two spirits mentioned above, and held in May. This is the pujah to ensure good crops in the

ensuing year.) The cures for them are roughly as follows:—

If, after the necessary ceremonies have been carried out by the old men of the village, it is discovered that it is due to not having carried out (i) correctly, then it is also necessary to find out which of the two spirits is angry.

If it is the dweller in the sky, then a red cockerel must be tied to a pole outside the house. It must be a red one or the spirit will not be placated. If it is the spirit of the earth, then the entrails of the cockerel are placed on the ground.

If it is due to failure to carry out (ii) correctly and the spirit of the sky is angry, then a squirrel (the small variety, called *bongko* by the Abors) must be tied to a post in the sufferer's house. If the spirit of the earth is angry, then the squirrel must be buried head foremost in the ground with rice and *apong*. There are several other details connected with the spirit of the earth of which the most important is that it is useless to bring the squirrel in any spot, as the spirit only lives in certain places. If a dog (which must be a red one) is used, or a pig, then they must be buried head first. Naturally it is first necessary to determine which offering will be acceptable.

The Gallongs do the same, with slight variations in the procedure. For instance, they eat the rest of the cockerel, after the entrails have been placed on the ground, and naturally their names for the spirits are different. The spirit of the sky is known as *talang*, the spirit of the earth is known as *sirumder* and they do not know them as husband and wife.

Beliefs held by Digaru Mishmis.—The symptoms of tuberculosis are recognized by the Digarus although it is probable that attacks of influenza and pneumonia, which end in the death of the sufferer, are sometimes mistaken for the same disease.

Dokhain is the tribal name for tuberculosis and its presence is usually accounted for by the village priest (*gwok*) of whom there is one in most, though not in all, villages. The *gwoks* say the disease is sent by a very evil spirit who cannot be appeased by any sort of pujah, the disease thus proving incurable. It is not however regarded as fatal until a second spirit, the death spirit, is sent into the sufferer. Pujahs are therefore performed with the object of trying to persuade the spirit of the village concerned not to send this second spirit into the sufferer as that would prove fatal at once. The pujahs are performed by killing fowls or pigs, half of which are put out for the spirits and half eaten by the people of the village. It is fatal to perform pujahs, however, without first consulting the *gwok* who thereby becomes the community-doctor, and is rewarded by gifts of opium and other suitable offerings. The only medicines used by the Mishmis for this are *Fatakkani* (Mishmi opium) and Mishmi *teeta*. The Government opium is said to be good to eat but is

of little use as a medicine compared with the Mishmi variety.

VI. Tribes of the North Cachar Hills

The population of the North Cachar Hills includes the following—Kacharis, Nagas, Mikirs and Kukis. Phthisis is believed to be fairly common among all tribes, but is more frequent among Kukis and Kacharis than among the others. The disease is well known among the hill tribes; the Kacharis call it *joka*. The Kacharis have certain medicines for it, but they do not claim to be able to cure it. It does not appear to them to be connected with any legendary beliefs, in contrast to the Kukis, who look on the disease as the result of their ancestors' wrong-doings.

Kacharis' houses are closed on all sides and measure about 30 feet by 15 feet with a mud plinth very seldom raised more than one foot from the ground; there are usually two openings, front and back; both of these are doors, there being no windows. The house is divided into two portions by a partition 12 feet high at the centre and 6 feet at the eaves. The first room is a sleeping room and the other is used as a kitchen. Separation or segregation of a tuberculous member of the family is therefore impossible in a house of this type, which has no verandah.

The Kuki's house is of the *chang* type, that is, it is built on posts, about at a height of some 3 feet from the ground. The floor is made of bamboo matting. There are no compartments, the house consisting of a single room, but it has a small back verandah which has no roof. This verandah might be roofed and used for a tuberculous person. The Mikir's house is similar to the Kuki's but higher off the ground, sometimes as much as 10 feet.

VII. The Manipuri tribes

There is some divergence between the customs and mode of life of the Manipuris of the hills, mostly tribes allied to Nagas, and those of the plains. Regarding the Manipuris of the plains, especially those who live in and near Imphal, there is one custom, which has a striking relevance to an anti-tuberculosis campaign,—that of building a *sangoi* or open shed, used for weaving and feasts, as part of the equipment of almost every Manipuri house, and which could readily be adapted as an open-air shelter for a tuberculous case, and might well be imitated by other communities as a communal *basha* if constructed on a rather larger scale.

VIII. Tribes of the Lushai Hills

In the Lushai Hills there is an excellent system, devised by the superintendent, Lushai Hills, by which matters of public interest are referred to the village welfare committees, under the presidency of the Lushai chiefs of villages.

These were formed so that executive orders could tend to be replaced by the acceptance by the people of good ideas for their own benefit from the point of view of health and otherwise. The organization, therefore, was of particular value in eliciting the kind of information the writer hoped to obtain through the good offices of the superintendent, Lushai Hills.

A questionnaire was addressed to these welfare committees including the following questions:—
(i) What did the Lushais of old think of tuberculosis or *ngawr*, and what method of treatment did they adopt and how did they treat those who were ill in this way? (ii) Was or is the belief held that *ngawr* is incurable? (iii) Was or is the belief held that this disease can be passed from one person to another? (iv) Was or is there any belief that *ngawr* was some form of vengeance or punishment by the evil spirits of old?

Added to this was a list of suggestions, based on the modern view of the prevention and cure of tuberculosis, and the committees were asked to say whether the suggestions would be acceptable to the tribesmen concerned and whether they would, on the whole, receive the support of the village committees.

The condensed answers to these questions are as follows:—

(i) Tuberculosis was regarded by the Lushais of old as a disease which went in families and it was not the general opinion that it was communicable between one family and another. It was generally believed that there was a danger of the disease persisting from one generation to another in the same family but the original infection was attributed to one of two causes in the case of the ordinary villages. The infection was either the result of witchcraft or of some offence against the social order as in the case of a man who ill-treated animals unnecessarily. In the case of chiefs or wealthy men infection was often held to be the result of jealousy on the part of a wizard who has hatred in his heart, or perhaps of over-feeding or drinking.

Sufferers from tuberculosis would always be well fed and nourished on the best available food which the patients might demand. At death if the symptoms included total swelling all over the body a public holiday or cessation from all ordinary occupation would be ordered. For the alleviation of suffering people resorted to sacrifices of various kinds. These sacrifices were called *mubu vial* or *sut zo ai*. If a priest was called in to perform sacrifice he would, on his return to his residence, have to perform a sacrifice before entering his home and if it so happened that the priest himself failed to cure the patient he himself would be in imminent danger of contracting the disease.

(ii) The disease was never considered to be incurable but the sacrificing priest should be stronger than the bewitching wizard responsible for the original infection. If the wizard was

detected the patient would seek the permission of the chief to kill his enemy and it was generally accepted by the Lushais of old that a cure would result from eating a portion of the dead man's liver. Some people were found to have dark marks on their skins, marks which could not be erased by washing. In such cases only the disease was considered to be incurable. Sacrifices involving the drinking of dog's blood, with or without turmeric, were said to be often efficacious in effecting a cure.

(iii) The general view to-day among the better-read and better-informed Lushais is that the disease can be spread through medium of a small germ invisible to the human eye except under a microscope, but the public, generally speaking, do not yet fully subscribe to this new idea. The older idea is that the disease, as already stated, was a family disease inherited from generation to generation till finally cured, and that it is not contagious at all.

(iv) There is no trace of the belief that tuberculosis was a disease associated with vengeance from superior gods or spirits. It was capable of generation by a wizard directing a spirit of hatred towards one of whom he was jealous. The object of this bewitching was the gain of property or mere personal hatred.

(v) It appears that in almost every case the people are quite willing to subscribe to the suggestions set before them and in many cases it is said that certain of the conditions such as partial segregation of the infected persons from the rest of the family are feasible and in themselves desirable. Only in one case in a distant village, not far from the Burma frontier, was it said that partial segregation would not be acceptable because the majority of the villagers did not believe that the disease could be communicated among people by germs.

Thus, among the tribes of the Lushai Hills there appear to be, on the whole, no insuperable obstacles, from the point of view of tribal customs or beliefs, to the introduction of a system of prevention and cure based on modern knowledge.

DISCUSSION OF THE RESULTS OF THE ENQUIRY

From the ethnological standpoint, there are certain obvious points of resemblance between the beliefs held by the several tribes as to the nature of tuberculosis, and a general tendency to regard some kind of sacrifice as holding out a prospect of cure. In practically all the tribes considered, even including such linguistically dissimilar tribes as the Khasi-Syntengs and the Naga tribes, the original infection is believed to be due to supernatural causes, either by way of retribution for infringement of some tribal taboo, or, by means of witchcraft, in satisfaction of some personal vendetta. The Abor tribes, on the other hand, ascribe the disease to the action, more arbitrary than connected with any idea of

retribution for tribal or personal misdeeds, of specially powerful spirits.

It is fortunately possible, nevertheless, to discern in the beliefs of nearly all tribes quite clearly in the case of some, and more dimly in others, the concept of tuberculosis as a disease which is either a 'family' disease (which, in turn, might be hereditary or the result of the very close association inevitable in tribal houses), or actually communicable from an infected person to a person outside the family, the exception being in the beliefs of the Abor tribes, who alone, among the tribes considered, regard the disease as the result of more or less arbitrarily-acting spirit-forces.

It is reasonable to suppose, therefore, that propaganda, suited to the intelligence of the tribes concerned, and based on the fundamental conception of tuberculosis as a communicable disease, is more likely to receive acceptance and bear fruit among the tribes of the former group than of the latter, among whom the seed seems destined to fall on stony ground.

It is, on the other hand, disappointing to find no trace of any type of tribal 'cure' which is worth encouraging for its own sake, comparable, for instance, to that which is in vogue among certain African tribes. Among the Somali tribe which I have in mind, the cure consists of living alone under a particular banyan tree at an altitude of about 4,000 feet for six months, subsisting solely on camel's milk, and never entering a dwelling-house during that period. The difference between this form of 'cure' and the simpler form of modern sanatorium treatment of tuberculosis is merely one of detail, and, as a cure, it is unquestionably effective in appropriate cases.

In Assam we must deal with beliefs as we find them, and it is some encouragement to be able to establish that pulmonary tuberculosis has long been recognized among many tribes as communicable, a fact which was long in dispute even in western countries until it was finally established by the work of Robert Koch less than sixty years ago.

The essential importance of the concept of tuberculosis as a communicable disease lies in the fact that, if the disease be communicable, it must, *ex hypothesi*, be in some degree preventable, and it is this idea, above all others, that needs to be inculcated in the primitive mind, not only to enlist active tribal co-operation but also to combat the idea, often concurrently held, that infection with the disease is either predestined or the result of the action of supernatural forces, whether vindictive, retributive, or arbitrary.

The measure of success to be achieved in any anti-tuberculosis campaign among primitive tribes may well prove to be the measure in which the rational element in tribal beliefs (the germ of which exists, as this enquiry has shown) can be fostered and, at least in this sphere, made eventually to supersede the irrational.

Medical News

WARNING NOTICE TO REGISTERED MEDICAL PRACTITIONERS

As a number of cases of advertisement by registered medical practitioners, in the lay press and by means of hand-bills, have come before the Madras Medical Council in recent months, the Council has, at its last Meeting, held on the 17th April, 1939, decided to warn all registered medical practitioners that all kinds of advertisement—including even the opening of private institutions, inviting laymen to attend functions connected therewith and publication of same in lay papers—by registered medical practitioners will be considered as advertisement under section 6 of the WARNING NOTICE published by the Medical Council, and will be dealt with accordingly.

(Sd.) N. M. WILSON,
MAJOR-GENERAL, I.M.S.,
President, Madras Medical Council.

IMPERIAL SOCIAL HYGIENE CONGRESS

A REVIEW of the provisions made for children in residential houses in the province of Bombay was made by Dr. Shakir Mohamedi, D.O.M.S., L.M.S., at the Imperial Social Hygiene Congress, at B. M. A. House, Tavistock Square, W.C.1, on 10th July.

The Congress, which opened on 10th July and lasted the week, was attended by 150 delegates from all parts of the Empire. A message of goodwill from the High Commissioner for India was read to the Congress at the opening session, and Indian delegates included representatives of the Government of Burma, of the universities of Allahabad, Bombay, Punjab and Rangoon, of the Bombay Presidency Women's Council and the Bombay Social Hygiene Council.

Dr. Mohamedi told the Congress that institutions, provided in Bombay for the reception of children who are orphans, homeless, ill-treated, or offenders, fall mainly into three classes. These are:—

1. Schools established and run by the Government.
2. Schools established by voluntary organizations and practically maintained by Government.
3. Schools established by voluntary organizations and aided by Government in respect of children committed in court.

These schools accommodated altogether 2,050 children.

The schools, he said, were regularly inspected and provided a varied curriculum covering a number of industries. One of the difficulties which had to be faced, he pointed out, was that education had to be provided in at least three languages.

Employment was not easy to secure for boys owing to unfavourable economic conditions in the cities.

In the case of girls, the aim, he said, was to marry them from the institutes whenever possible because there were no openings for safe employment of girls. Marriage negotiations were in most cases carried out by a managing committee of the various institutions, and a careful selection of candidates was made among suitable applicants. The girls, Dr. Mohamedi said, made the final selection. As a rule they were married within their castes.

'IRON LUNGS' FOR INDIAN HOSPITALS. SIX IN CENTRALLY ADMINISTERED AREAS. LORD NUFFIELD'S GIFT

Six hospitals in centrally administered areas which are considered suitable for the supply will benefit from Lord Nuffield's offer of 'iron lungs', or respirators, to hospitals in the British Empire about which an announcement was made some time ago. These hospitals are the following:—

1. Ross General Hospital, Port Blair.
2. New Victoria Hospital, Ajmer.

3. Civil Hospital, Mercara.
4. Irwin Hospital, New Delhi.
5. Lady Hardinge Medical College and Hospital, New Delhi.
6. Civil Hospital, Quetta.

Provincial Governments have been asked to communicate their requirements direct to the High Commissioner for India for transmission to the appropriate authorities.

Only those hospitals have been selected for receipt of the 'iron lungs', which can provide for skilful handling and maintenance of the apparatus in perfect working condition. The apparatus is worked by electricity, but in an emergency can also be operated by hand. Hand operation is, however, laborious and the machine is not recommended for use where electric supply is not available.

Though associated in the popular mind almost exclusively with the treatment of respiratory paralysis following upon infantile paralysis, the machine is of value in many other conditions of respiratory disorder as well. For example, it is used extensively in the United States of America for the treatment of loss of consciousness following gas poisoning and poisoning from other drugs.

A film has been made demonstrating both how the machine can be kept in order and how nurses have to deal with patients in the machine. The film is 16 mm. in size and can be had at a cost of approximately £3 from School Films Ltd., 498a, Oxford Street, London, W.1.

The respirator is delivered free at Cowley, Oxford, and transport and other charges have to be borne by the recipient. The total weight of the apparatus is just under 4 cwt. and it takes up slightly more room than a single bed. It is anticipated that deliveries will begin shortly.

It is Lord Nuffield's intention to manufacture the necessary number of 'iron lungs' and then to close down this part of his works.

POST-GRADUATE STUDY IN GREAT BRITAIN

WOMEN medical students and doctors who are planning post-graduate studies abroad are invited to correspond with the Chief Medical Officer, Women's Medical Service, Countess of Dufferin's Fund Office, Viceregal Estate, Simla (summer), Red Cross Building, New Delhi (winter), from whom advice can be obtained before leaving India about the various diplomas and courses of study available, the qualifications needed for each, and in general about facilities for residence and study abroad.

In England the services of the High Commissioner for India are available for similar advice.

Applications should be made to the High Commissioner's Education Department which is assisted in this matter, where necessary, by the Countess of Dufferin's Fund Medical Adviser in London.

Students are strongly advised not to leave India without assurance that they are qualified for admission to the examinations they intend to take.

(Sd.) G. STAPLETON,
Chief Medical Officer, W. M. S.

DR. H. DE SA SILVER JUBILEE PRIZE

THE Bombay Obstetric and Gynaecological Society has selected the following subject for the thesis for the above prize for 1939-40:—

Displacements of uterus.

The prize is open to all medical persons registered with the Bombay Medical Council and of not more than five years standing. Time to submit the thesis will be some time in March 1940.

For further particulars write to Honorary Secretaries of the Society, Empire Automobile Building, Queen's Road, Bombay, 4.

ACTION OF QUININE AND THE SYNTHETIC DRUGS ON MALARIA

(FROM 4TH GENERAL REPORT OF LEAGUE OF NATIONS MALARIA COMMISSION)

Issued by Malaria Institute of India

	ACTION ON TROPHOZOITES		ACTION ON GAMETOCYTES		ACTION ON ACUTE SYMPTOMS		Action on frequency of relapse	Action on spleno-megaly	Effect on general condition of patient
	B. T. + Q.	M. T.	B. T. + Q.	M. T.	B. T. + Q.	M. T.			
Quinine	Daily dose of 1 g. (15 grs.) causes disappearance, 5 to 7 days.	Daily dose of 1.3 g. (20 grs.) causes disappearance, 5 to 7 days.	Affects pre-gameto-cytes and gameto-cytes.	Affects pre-gameto-cytes but gameto-cytes only very slightly.	Marked action from 3rd day (2nd paroxysm).	Variable action from 3rd or 4th paroxysm.	Acts on all species but in B. T. and Q. relapse rate may reach 50 per cent.	Acts on all species but effect is transient where reinfection or relapses are frequent.	No effect if treatment is limited to number of days essential.
Atebrin	Daily dose of 0.3 g. causes disappearance, after 3 days. Effects last longer than quinine.	Daily dose of 0.3 g. causes disappearance, after 4 days in 90 per cent of cases.	Similar to quinine but slightly more marked.	Similar to quinine.	Very marked action. Fever falls by 2nd paroxysm.	Marked action. Fever usually falls by 3rd paroxysm (but with some strains effect is less than quinine).	Action slightly more than quinine especially in B. T. and certain strains of M. T.	Effect somewhat slower than quinine but seems to last longer.	Sometimes yellow coloration of skin.
Plasmochin	Slight action only.	Practically no action.	Definite action in both species.	Marked action in minimum doses of 0.02 g.	No indications for using plasmochin alone for treatment of acute attack.		Definite effect in B. T. and Q. In association with quinine and atebrin it has a marked effect in reducing relapses in all 3 species.	Insufficient data.	In the doses now used (e.g., 0.02 g.) it seems to have no depressing effect.

Notes

A.—ACTION OF COMBINATIONS OF DRUGS

1. There is no advantage in combining quinine and atebrin in treatment.
2. Quinine + plasmochin simultaneously produce less frequent and less intense toxic symptoms than atebrin + plasmochin, but are best given consecutively where possible. Quinine (15 to 20 grains daily, 7 days) + plasmochin (0.02 g. daily, 5 days*) are probably the best treatment for B. T. and Q. malaria.
3. Simultaneous administration of atebrin and plasmochin aggravates the toxicity of each and is not recommended. Consecutive treatment with atebrin (0.3 g. daily, 5 to 7 days) and plasmochin (0.02 g. daily, 5 days*) has no advantage in the primary attack, but acts on gametocytes and relapses in the same manner as quinine and plasmochin treatment.

B.—PRACTICAL SUGGESTIONS FOR TREATMENT

1. *Individual treatment.* Quinine (15 to 20 grains) or atebrin (0.3 g.) 5 to 7 days, followed by plasmochin (0.02 g.) 5 days, or quinine + plasmochin simultaneously.
2. *Treatment in field.* Quinine (15 to 20 grains) or atebrin (0.3 g.) 5 to 7 days, followed by plasmochin (0.02 g.) 5 days if funds and medical supervision are available. But if, as is usual, this is not so, short treatments with the cinchona alkaloids are more suitable.
3. *Mass drug prophylaxis.* Daily doses of quinine (0.4 g. or 6 grains), or bi-weekly doses of atebrin (0.2 g.).

*For gametocidal purposes alone, however, one dose of 0.02 g. plasmochin followed by a second dose, if necessary, on the 5th day is equally effective. It may be noted also that in one mass treatment experiment (in Sardinia), the daily administration of 0.02 g. plasmochin had to be stopped after 3 days on account of toxic symptoms.

TUBERCULOSIS ENQUIRY. INVESTIGATIONS AMONGST JUTE MILL OPERATIVES. DANGER TO CHILDREN IN OVERCROWDED HOUSES

A TUBERCULOSIS enquiry undertaken by the All-India Institute of Hygiene and Public Health, Calcutta, is in progress at the Angus Jute Mills, 23 miles from Calcutta, which employ 5,000 labourers from various parts of India. It is fortunate for the investigation that the mill possesses a good laboratory and a useful x-ray plant.

Two hundred and sixty-three workers have been selected as samples from various departments of the mill (ten in number) and put to a thorough examination including physical, sputum and blood tests, and chest skiagraphy. The previous life of the worker, the details of industrial life with age at entry, duration and nature of work, his financial status, housing and other relevant points have been recorded.

About 1.9 per cent of the workers were labelled as 'definite' cases of pulmonary tuberculosis, 5.3 per cent as 'possible' cases and 59 per cent as 'arrested' or healed lesions.

The 'batching', 'preparing' and 'spinning' departments have been taken up first and so far 1,360 workers have been tested and examined. Physical findings suggestive of pulmonary tuberculosis have been found in 48 cases. Both exaggerated tuberculosis reaction and suspicious physical findings have been detected in twelve. Bronchitis has been detected in 224, and catarrh in 49 persons.

The different processes through which the jute-fibre passes to be finally baled produce a large amount of dust. In order to determine the size and concentration of suspended dust particles, 144 samples from various departments have been examined. A majority of the dust particles were below five microns in size.

EXAMINATION OF CHILDREN

About 221 children below 15 years have been examined and followed up since last year, bringing the total to 838. Owing to the difficulty of a home survey of scattered houses and of bringing the contacts for x-ray and other investigations and to certain unavoidable difficulties about x-ray service in the hospital, the progress has not been as rapid as was expected.

It is proposed to examine completely 1,000 cases before final deductions are drawn. As soon as the homes of tuberculous patients are surveyed, a study will also be made of a certain number of homes of non-tuberculous individuals, if possible, for purposes of comparison.

In all, 110 tuberculous homes, containing 319 children, have been surveyed, of which 94 contained 'open' pulmonary tuberculosis cases. Sanitary condition was bad in 56 per cent of the houses and 39 per cent of the houses were one-room tenements. About 49 per cent of the houses contained inmates with a low economic status; the average monthly income per head being less than five rupees. Nearly 56.7 per cent of the contact children lived in houses with bad hygienic conditions and 36.6 per cent in one-room tenements.

Out of 319 children, 196 slept in the same room with the patient who was the source of infection. As the majority of cases belonged to the poor classes, no significant correlation could be found between the incidence of infection, morbidity rate and economic status.

FOURTH MAHARASHTRA AND KARNATAK MEDICAL CONFERENCE

THE joint honorary secretaries of the Fourth Maharashtra and Karnatak Medical Conference, Nasik, inform us that the fourth session of the Maharashtra and Karnatak Medical Conference will be held at Nasik on 3rd to 5th November, 1939 (both days inclusive). Dr. V. R. Khanolkar, B.Sc., M.D. (Lond.), head of the pathology department and professor of

pathology, S. G. S. Medical College, Parel, has kindly consented to preside. There will be discussions on the streptococcal infections, their bacteriology, diagnosis and treatment. All medical men are requested to attend the conference.

OPIUM SMOKING IN INDIA. HABIT DECLINING

INVESTIGATIONS on opium smoking in India have been completed at the School of Tropical Medicine, Calcutta.

It has been found that while the habit is particularly prevalent in Assam and the Central Provinces, it is met with in one form or other on a small scale in many of the large towns of India. The habit has considerably declined during the last 30 years.

The method of preparing opium for smoking, the modes of indulgence, the type of addicts have been studied. In areas where this practice is common, social and economic factors were instrumental in the spread of the habit.

The main causes of addiction have been found to be association with other addicts, disease or minor ailments, hard work, worry or strain. The dosage in a series of 300 cases studied ranged from 1 to 180 grains of opium daily.

The effects produced by the habit have been studied. The conclusions briefly are that excessive indulgence produces (1) economic loss by reducing the earning capacity of the addicts; (2) damage to health and loss of physical energy and deterioration of intellect; and (3) curtailment of longevity.

The work on the hemp drug habit in India is nearing completion.

BULLETIN OF THE HEALTH ORGANIZATION. VOL. VIII, NOS. 1-2

THIS new number of the *Bulletin* starts with the *Annual Report of the Health Organization of the League of Nations*.

Prevention and treatment of malaria, cancer, leprosy, bilharziasis and rabies; medico-social action in the sphere of rural hygiene, nutrition, housing and physical education; epidemiology and health statistics; biological standardization; campaign against narcotic drugs; unification of pharmacopœia; and anti-epidemic action in China—such are the headings of this report, the mere enumeration of which shows the wide field of action covered by the League of Nations in its work of international co-operation and in its efforts to raise the standard of health.

The second article, entitled *Health Indices*, is a skeleton standard report for use in surveys of the state of health and vitality of a given population. It contains numerical indices, incorporated in various chapters, which can be applied equally to urban or rural areas, or to a whole country, thus rendering the results numerically comparable.

Next comes the report drawn up by M. Vignerot (France) on *Rural Housing and Planning*. The first part of this article deals with the rural house and its outbuildings; the author reviews the general measures which should be taken to improve rural housing. The second part is concerned with community planning, and the third part with questions of area planning, showing the present situation and tendencies in the various countries.

The last article in this number of the *Bulletin* consists of a vast study of 260 pages drawn up by Dr. Walch-Sorgdrager on *Leptospirosis*. This comprehensive report deals with the epidemiology, clinical features and prophylaxis of leptospirosis in man and describes the various clinical forms of human leptospirosis, symptomatology, diagnosis, complications and treatment. The bibliography is the most complete one to be found on the subject.

BENGAL COUNCIL OF MEDICAL REGISTRATION

IN pursuance of section 7 of the Bengal Medical Act, VI of 1914, as amended by Bengal Act III of 1928, it is notified for general information that Lieutenant-Colonel J. C. De, M.A.C.P. (London), I.M.S., Officiating Principal, Medical College, Calcutta, has been duly elected to be a member of the Bengal Council of Medical Registration under clause (d) of section 4 of the said Act, *vice* Lieutenant-Colonel T. C. Boyd, D.P.H., I.M.S., I.M.S.

RAI SHAMBHU DAYAL SAHIB GOLD MEDAL

1. A gold medal called the 'Rai Shambhu Dayal Sahib Gold Medal' will be presented for the best prize essay on a public health subject to be announced each year.

2. The subject of the next essay is 'A Scheme for Physical Culture in Rural Areas'.

3. The competition will be open to the general public, including the medical and the public health workers in the United Provinces.

4. The essay is to be written in simple Hindi and should not exceed 3,000 words in length.

5. Essays should reach the Medical Officer In-charge, Provincial Hygiene Institute, United Provinces, Lucknow, by 15th November, 1939.

6. The name and address of the competitor must be distinctly written on each essay submitted and the envelope should have the words 'Prize Essay' in the top left-hand corner.

7. The Director of Public Health, United Provinces, shall judge the merit of the essay and his decision with regard to the award of the medal shall be final.

8. No correspondence will be entered into on the subject of the competition.

9. No essay will be returned.

MEDICINE AND THE PRESENT EMERGENCY

THE following message from members of the British medical profession has been sent to American citizens at the World Assembly for Moral Re-Armament, Golden Gate Fair, San Francisco:

'In the continuing uncertainty of world affairs, medical practitioners in common with others are deeply concerned to restore the security essential to normal living. It is vital to create confidence during an emergency, but even more urgent to prevent catastrophe and to lay the foundation of a just and lasting peace.'

'Science has made great advances, but without corresponding moral progress we risk losing even the benefits already achieved.'

'Behind much disease, as behind world unrest, are fear, self-indulgence, jealousy and resentment. These are problems for which Medicine might provide a radical solution.'

'It is still our privilege to enjoy unrivalled contact with the homes and people of the nation. Our immediate task is to teach men that health is not the mere absence of disease but includes a moral and spiritual foundation for life and the replacing of conflict and apathy with a purpose that claims the whole personality in the service of our fellows.'

'A growing body of people in many countries is calling for this "moral re-armament" to provide the discipline and the direction needed by both individual and nation. Our profession can give a lead to such a programme which is in accord with the highest ideals of our tradition. To achieve it we realize that the highest standards of honesty and unselfishness must be the touchstone of our professional and private lives. Only through insistence on these spiritual values will the resources of science be liberated and a new world built in which men can attain to their inherited capacity for physical, moral and spiritual development.'

Current Topics

Clinical Aspects of Pneumothorax Therapy as Illustrated by the Results obtained in 191 Cases of Completed Treatment*

By OLI HJALTESTED

and

KJELD TÖRNING

(Abstracted from the *British Journal of Tuberculosis*, Vol. XXXIII, January 1939, p. 4)

WITH a view to showing a statistical justification for pneumothorax therapy and to establishing the value of this therapy, the authors give an account of the late results of this treatment in 191 patients within the period 1925-31. The results are recorded under three sections: first, results in relation to the factors known at the institution of the treatment; second, in relation to the anatomical character of the pneumothorax obtained; third, correlation and comparison of the results with regard to original factors and to the subsequent phenomena occurring in the course of the treatment.

The results of the treatment according to sex, age, disposition to tuberculosis, duration of illness prior to treatment, localization of the disease, presence and size of the cavity, differ slightly as the distribution of 'good' and 'poor' pneumothorax in these groups is almost uniform. The results are distinctly favourable in unilateral cases, afebrile and sub-febrile cases and in cases with sedimentation rate under 30 in the

beginning. The late results depend on the pneumothorax obtained. Pneumothorax is generally poorer in febrile cases and it is incomplete in cases with unseverable adhesions. With ideal pneumothorax 80 to 90 per cent of the patients became well, whereas with incomplete pneumothorax the same percentage of patients died. The authors concluded that the adhesions to the chest wall should be severed by cauterization, pneumothorax once instituted should be carried out completely, and that incomplete pneumothorax should be given up and replaced by other operative treatment. In empyema, the prognosis being poor, early radical treatment is indicated.

P. K. C.

The Pathogenicity of B.C.G. after Prolonged Cultivation on Glycerinated Egg Medium

By W. H. FELDMAN

(Abstracted from the *Tubercle*, Vol. XX, March 1939, p. 253)

IT is stated by Calmette that the strain of tubercle bacilli known as B. C. G. is definitely and permanently innocuous and it is also said that to preserve its avirulent state the strain should be periodically subcultured on ox-bile-glycerinated potato medium. Attempts to increase the virulence of B. C. G. by culture were made by many workers. No evidence of increased virulence was observed by most of them. According to the author, the term 'virulence' should be distinguished from the term 'pathogenicity'. That the organism has at least a limited pathogenicity has been admitted by Calmette and demonstrated by many. The author made an attempt to increase its pathogenicity by sub-culturing the organism for fifty-

*This, and the following eight abstracts, were selected for the special tuberculosis number, but were excluded on account of lack of space.—EDITOR, I. M. G.

nine generations on glycerinated egg-yolk slants. The bacteria were then inoculated into guinea-pigs and rabbits subcutaneously, intra-peritoneally, or intravenously. The observation was extended for 453 to 455 days when the surviving animals were killed. When the animals died or were killed, they were carefully examined at necropsy. The principal organs were histologically examined and tissues were emulsified for making cultures and for inoculation of additional animals. In no instance was a progressive tuberculous disease observed. Tuberculosis-like lesions were observed in some instances, consisting of epithelioid tubercles which were frequently quiescent or atrophic. Attempts at re-inoculation by tissue emulsions of these lesions failed invariably. Thus, the findings indicate that cultivation of B. C. G. for fifty-nine generations (approximately 6 years) on glycerinated egg medium did not increase its virulence for guinea-pigs or for rabbits.

S. R. G.

A Study of the Results of Treatment of Pulmonary Tuberculosis in Mexican and White Patients

By F. R. HARPER

(Abstracted from the *American Review of Tuberculosis*, Vol. XXXVII, May 1938, p. 556)

THE form and the course of tuberculosis had been studied in 290 white and 53 Mexican patients. All these were workers on the railways. In the group of Mexican patients 66 per cent had hæmatogenic and exudative forms of disease and only 25 per cent showed a predominantly productive type of disease. As a marked contrast amongst the white group only 8 per cent were hæmatogenic and exudative, and 89 per cent were predominantly productive. Cavities were detected in 41 per cent of the Mexicans and 63 per cent of the whites. Extrathoracic tuberculosis was detected in 49 per cent of the Mexican and 20 per cent of the whites.

Regarding the results of treatment the Mexican patients did not react as well as the whites. During the course of treatment 32 per cent of the Mexicans died and in 5 years from the onset of the disease 47 per cent died. White patients, as a contrast to this, reacted much better. Only 11 per cent died during the course of treatment and 21 per cent in 5 years time.

P. K. S.

On the Frequency of Relapse after Pneumothorax Therapy in Pulmonary Tuberculosis with Cavity Formation

By SIGURD COLD

(Abstracted from the *Tubercle*, Vol. XX, April 1939, p. 301)

THE author investigated the rate of relapse in 106 patients under or after artificial-pneumothorax (A-P) treatment who have been inactive for at least one year. Renewed activity of lesions was observed in 21 or 20 per cent and tubercle bacilli were temporarily found in sputum or gastric lavage without any other signs of activity in 9 or 8.5 per cent. The time distribution of the relapses were as follows: 11 in the 1st year, 6 in the 2nd year, 3 in the 3rd year and 1 in the 8th year of observation. Thus, the risk of relapse is greatest in the 1st year but decreases rapidly. In all the 20 patients that relapsed within the first 3 years of observation A-P was being continued except in one. Hence these relapses could not have been due to early discontinuance of A-P.

Eighty-one patients have been observed for at least one year after cessation of effective A-P treatment. Amongst these, relapse was found in 3 and only transitory positive sputum in 4. It has not been possible to establish the significance of the duration of collapse with the frequency of relapse. After 3 or

4 years of inactivity, the frequency of relapse is not seen to be higher than the incidence of active tuberculosis in previously healthy persons in the same age group.

P. K. C.

The Treatment of Surgical Tuberculosis in Adults

By M. FORRESTER-BROWN

(Abstracted from the *British Journal of Tuberculosis*, Vol. XXXIII, April 1939, p. 107)

THE author considers the problem of surgical tuberculosis in adults from three aspects, namely—

(1) *Provision of facilities of treatment.*—At present such facilities are inadequate and, even where present, the after-care from the dispensaries is unsatisfactory. Thus, the desirability of establishing institutions for surgical tuberculosis cases to work in close association with orthopaedic hospitals and with proper arrangements for after-care is stressed.

(2) *Early diagnosis.*—It is very difficult on account of the absence of characteristic signs and of x-ray changes until considerable destruction of bone has already occurred, and to the fact that the patients do not seek medical advice until an abscess is formed or they are incapable of carrying on their work. The doubtful cases of 'lumbago', 'sciatica' or 'rheumatic joints' should be kept under observation in hospitals for final diagnosis and treatment.

(3) *Patient's co-operation.*—Educative propaganda should be made to produce the willingness on the part of the patients to seek early treatment. That the disease is curable and return to useful life is only possible, if treated early, should be stressed.

Provisions should also be made so that patients, when made fit can get work suited to their restricted capabilities.

The Results of Phrenic Evulsion in Upper Lobe Cavitation after Six Years

By A. WILSON RUSSELL

(Abstracted from the *Tubercle*, Vol. XX, March 1939, p. 277)

THE author reports the results of a series of 50 cases in which phrenic evulsion was performed to control upper lobe cavitation and which have been followed for a period of six years. Artificial pneumothorax was primarily attempted in every case and it was effective only in 4. The immediate beneficial effect (within 3 months) of phrenic evulsion on cavities was obtained in 54 per cent or 25 cases out of the remaining 46 cases in which artificial pneumothorax was either ineffective or partially effective. As late results after an interval of six years following phrenic evulsion, 19 out of 25 immediately benefited from the operation were alive (76 per cent), only 8 out of 21 which derived no benefit were alive (38.1 per cent), and 3 out of 4 in which artificial pneumothorax was effective *per se* were alive (75 per cent), i.e., 30 out of 50 (60 per cent) were alive after six years. The author concludes that phrenic evulsion has a definite value in the control of upper lobe cavitation as a sole procedure and especially in combination with artificial pneumothorax.

Über den Wert der Kollapsbehandlung bei Lungen-tuberkulose. (On the Value of Collapse Therapy in Pulmonary Tuberculosis)

By F. LOMMEL

(Abstracted from *Deutsche medizinische Wochenschrift*, Vol. LXIV, 10th June, 1938, p. 852)

THE course of pulmonary tuberculosis is very varied and it is also very difficult to estimate the value of any particular therapy. Signs and symptoms are not

so very valuable in this direction. The 'openness' or 'closedness' of a case after treatment are much more valuable data in the assessment of a case.

The author thinks that any assessment of the result of a treatment is untrustworthy if the cases are not followed for at least two years. He followed 871 cases with unilateral pneumothorax for 2 to 12 years. Amongst this group 48.7 per cent died and 51.3 per cent were still living. Of those living 12.9 per cent were diseased, 38.4 per cent were closed. After 9 to 12 years about 60 per cent were dead. This result could only be compared if similar cases without pneumothorax could be kept as controls. Raikowski compared his 138 pneumothorax cases with 76 controls where pneumothorax was indicated but was not possible for adhesions or other causes. In the group of treated cases 51 per cent died within 2 to 15 years, whereas in the untreated cases 76 per cent died in the same time. In the treated group 31 per cent were able to continue their working lives, whereas in the untreated group only 12 per cent reached this stage. Ahlenstiel gave 20 per cent better results in the treated than untreated, and Herrmann gave 43 per cent improvement in the treated and 23 per cent in the untreated. The author found the death rate in the untreated group to be 63.1 per cent and in the treated group to be 38.9 per cent. Regarding sputum findings 21 per cent became closed in the uncollapsed group and 50 per cent in the collapsed. Finally, he thinks that the comparative possibility of healing in the collapsed and non-collapsed cases are 100 to 42.

Blutenzyme und Tuberkulose-abwehr. (Blood Enzymes and Resistance against Tuberculosis)

By B. SCHOLZ

(Abstracted from *Deutsche medizinische Wochenschrift*, Vol. LXIV, 11th March, 1938, p. 374)

PANTSCHENKOS thought that an effective ferment against tuberculosis might be produced by the help of an albuminous body and a vitamin. The author tried to investigate this side of the question by finding out the influence of ascorbic acid on the lypolytic ferments of human blood. He found that it raises the level of estrase and specially that of lipase. With Pantschenkos he tried to find out the utility of this method in the treatment of tuberculosis. It was thought probable that such an application of a ferment might destroy the wax covering of the tubercle bacilli, make them less resistant, more liable to chemical treatment, and diminish their multiplication.

It has been seen in animal experiments and also in observations in men that vitamin-C deficiency causes a flaring up of the disease. It has been specially noticed in the month of December, January and February when the vitamin-C containing foodstuffs are least available and tuberculosis spreads most. It, therefore, seems probable that an enzyme containing vitamin C may well be usefully employed in the treatment of tuberculosis.

Zur Prognose der Tuberkulose im Säuglings- und Kleinkindesalter. (The Prognosis of Tuberculosis in Infants and Small Children)

By J. BETLE

(Abstracted from *Zeitschrift für Kinderheilkunde*, Vol. LX, 1938, p. 95)

THE reported mortality rate of tuberculosis in early childhood varies a great deal in literature. By some it is noted as high as 75 per cent and by others as low as 20 per cent. The author investigated 514 infants and small children who were treated in the children's hospital of Tolz from 1931-35. The follow-up of the

children from 1 to 8 years from the time of infection produced the following results:—

(1) Thirty-six children were infected within the first 6 months of their lives. Amongst these 25 became inactive, 1 was active, 5 died of tuberculosis, and 1 of pneumonia.

(2) Sixty-four children were infected in the age period 6 to 12 months. Amongst these 53 became inactive, 6 active, 1 died of tuberculosis and 1 of unknown cause.

(3) Forty-four children were infected in the age period 12 to 18 months. Of these 36 became inactive, 2 active, 4 died of tuberculosis and 2 of other causes.

(4) Ninety-four children were infected in the age period 18 to 24 months. Amongst these 77 became inactive, 5 active, 4 died of tuberculosis and 3 of other lung diseases.

(5) Two hundred and seventy-five were infected in the age period of 2 to 5 years. Amongst these 255 became inactive, 8 active, 2 died of tuberculosis and 2 of other causes.

Amongst all the children 27 (=5.4 per cent) died. Of these 18 (=3.6 per cent) died of tuberculosis. Sixteen died from generalized spread of whom 12 had meningitis. In one there was caseous pneumonia and in another abdominal tuberculosis.

The tuberculosis of right-sided para-tracheal glands seemed to be dangerous as in many such cases meningitis occurred.

The prognosis, therefore, is better than is given in the literature generally.

Treatment of Haemorrhoids

By P. McEVEDY, F.R.C.S.

(From the *Medical Press and Circular*, Vol. CXC VII, 14th December, 1938, p. 542)

DISEASE of the venous system is common, and being progressive, eventually calls for treatment. The early symptoms are mild and painless and are generally treated with homely but futile remedies and it is not until the condition is well established that medical aid is sought. A person consulting his doctor for piles has the usual patient's confused idea that this diagnosis includes all rectal complaints; he has tried a multitude of ointments and suppositories and has failed to note the inevitable progress of the disease.

An exact and detailed diagnosis must precede treatment. Besides a general examination, this necessitates inspection of the anus, digital and proctoscopic examination. The treatment will depend on the type of piles, whether external, internal or inter-external; the stage to which they have progressed, and the presence or absence of complications.

EXTERNAL PILES

These can be seen on inspection of the anus and consist of skin tags which may contain dilated veins. These are a common cause of pruritus, are subject to attacks of inflammation and should be removed. Under local anaesthesia they are cut off with scissors level with the skin—no stitches are applied, and the wound is allowed to heal by granulation. The dressing and subsequent treatment is as described later, following operations for piles.

INTERNAL PILES

These can only be diagnosed by inspection through a proctoscope. They may be treated by palliative means, by injections or by operation. In the early stages the only symptom will be occasional slight bleeding, and the only requirement is that the patient should observe the elementary rules of life. Moderation in food and drink, regular habits in work, recreation and rest, and as little interference with the natural bowel action as possible forms the basis of treatment. Aperients, especially salines, are to be avoided, as attacks of diarrhoea aggravate piles much more than constipation. The bowels can be regulated

by a mixed diet, sufficient fluids, and, where necessary, liquid paraffin.

About 80 per cent of patients with piles can be treated by injections. The following points were emphasized by an investigation of cases treated at Ancoats Hospital: (1) The best results are obtained in men with internal piles, 60 per cent being free from symptoms after five years. (2) Women who have had children will derive only temporary improvement and when the perineum is torn there will be practically no improvement. Women who have not had children will show a 40 per cent cure for two years, but there will be less than 10 per cent of five-year cures. (3) Large fibrotic piles are obviously unsuitable as the injections only add to the fibrosis, which has already stopped the bleeding, but which increases the tendency to prolapse. (4) The more advanced stage the piles have reached, the less hope there is of a cure by injections. (5) Piles cannot be injected in the presence of complications. When a fissure is present injections would be too painful and even if the treatment is postponed until the fissure is healed the manipulations are likely to cause a recurrence. (6) When recurrence follows a course of injections a second course will likewise fail, and the period of relief will be shorter.

INJECTION TREATMENT

No special preparation is required, but the patient is advised to avoid aperients and liquid paraffin. If a small amount of faeces is present it can be displaced upwards by swabs of cotton-wool which need not be removed afterwards. Suitable instruments are essential and must be sterilized by boiling, as the solutions used are only mildly antiseptic. Down Bros. make for me a lighted speculum and needles that do not become blocked. The solution now in common use is 5 per cent carbolic acid in almond or olive oil. A few patients, especially those who have suffered from kidney disease, show an idiosyncrasy to carbolic acid, so caution is necessary in beginning the treatment and in using large injections. For the last two years at Ancoats Hospital I have used $7\frac{1}{2}$ per cent eugenol in olive or almond oil and have found it most satisfactory and non-toxic, but rather painful if given too quickly.

The injection is submucous and causes a bluish stippled swelling. If injected into the mucous membrane this becomes milky white and a superficial painless ulcer will follow. The first injection is given high anteriorly and should be 5 to 7 c.c. of the carbolic or 7 to 10 c.c. of the eugenol. The second injection a week later, of a similar amount, is given posteriorly. This injection is given a quarter of an inch above the dentate line, as, if attempted higher, the needle pierces the mucous membrane and the solution flows into the rectum. On the third occasion 3 to 4 c.c. is given on each side. Should marked improvement occur the fourth injection is postponed a few weeks, and is given right anterior and left posterior. A few weeks later the final injection is given left anterior and right posterior. Where prolapse is the predominant symptom it is important that the injection should be large, and at intervals of not longer than a week until the prolapse has ceased. In elderly patients with obstinate bleeding multiple small injections given just above the pectinate line will succeed where the usual injections have failed.

COMPLICATIONS FOLLOWING INJECTIONS

These may be due to the oil, the drug, or to faulty technique. The oil should be of the best quality, sterilized according to the B. P. formula, then filtered, otherwise the patient may develop influenza-like symptoms and be confined to bed for a few days. Failure in asepsis, using old solutions, especially if exposed to the air, or allowing water to mix with the solution, may account for similar symptoms. Some years ago we had four cases of unconsciousness in strong, healthy men following a first injection. Unconsciousness occurred rather suddenly, one to two hours after the injection, was of short duration, caused no after effects and did not occur at subsequent treatments. A rather

large dose of carbolic may have accounted for this, also for a few cases of mild transient cerebral symptoms and some that showed blood and albumin in the urine.

Pain following an injection is generally due to faulty technique, but may be due to a healed fissure having recurred after the use of an instrument. Pain follows if the injection is below the dentate line, is into the rectal muscle, or is given in such quantity or under sufficient pressure to produce necrosis. In spite of every precaution pain will occur at intervals and is possibly due to excessive thrombosis. The more the fibrosis the less the diffusion: this must be remembered at the later injections and when the treatment is repeated. Reduction of prolapsing piles must be maintained following injections, otherwise ulceration will follow. A thrombosed external pile occurring during a course of injections is probably independent of the treatment.

Primary hæmorrhage is not uncommon when the needle is withdrawn, and though slight should be stopped by swab pressure before withdrawing the speculum. Secondary hæmorrhage, which was a rare complication when 20 per cent carbolic was in common use, should not occur, and, like ischio-rectal abscess, is due to lack of asepsis or to using an excessive quantity of solution. Painful and frequent micturition may follow an anterior injection given too deeply, but this will not happen if the mucous membrane is seen to move freely with the needle.

INTERO-EXTERNAL PILES

These can be seen on inspection of the anal orifice as the varicose condition spreads down to involve the external hæmorrhoidal veins, and produces a bluish congested appearance. It is the type found commonly in women; also in males when the piles are of long standing. Occasionally a single anterior intero-external pile develops before the age of twenty, nearly always in females, and in a few years shows chronic prolapse of its mucous membrane. This pile cannot be improved by injections and must be removed by operation. Injection of intero-external piles in men may give freedom from symptoms for one to two years, or, if repeated, for as long as five years, but a permanent cure is unlikely. Unless there are contra-indications these piles are best treated by operation.

OPERATION FOR PILES

The patient is prepared by giving an enema the evening before the operation. The anæsthetic should be a low spinal or a local, and I find that, with rare exceptions, a local with adequate pre-medication is the most satisfactory, but it requires more experience than local anæsthesia for other regions. It is generally agreed that the excision and ligature operation is the one of choice, and can be used for practically all cases requiring operation. The sphincter is not stretched unless a fissure is present. Taking 12 to represent the mid-line anteriorly, the primary piles at 3, 7 and 11 should be removed with an adequate oval portion of skin, but the mucous membrane must not be stripped up above the lower edge of the internal sphincter muscle. Only the pedicle is tied, preferably with thread, no stitches are used, and undermined or redundant skin is removed. An efficient dressing is a strip of gauze, well lubricated with Amcran or Tannafax, one end of which is passed into the rectum and the rest is bunched up over the anus and maintained securely in position until next morning by elastoplast stretching from the sacrum to either side of the pubes in front. This dressing prevents primary hæmorrhage and skin edges adhering. On the second day after operation the patient commences to take liquid paraffin night and morning, and is given a mixed diet, but fruit and vegetables are avoided until after an aperient has been given on the fourth or fifth day. After the bowels have acted paraffin is taken as required, and the daily bath is resumed. Recurrence following an operation is rare and should lead to a suspicion of some degree of portal obstruction, or of gross departure from a healthy mode of life. Any

remaining pruritus is treated by scrupulous cleanliness and by rubbing in calomel powder.

It is common for treatment to be first called for when complications have developed.

Thrombosis followed by ulceration, especially of prolapsing piles, is usually found when the patient complains of an attack of piles. One or more internal piles are seen to be protruding, and may be ulcerated and surrounded by a ring of oedematous skin. Only in the first few hours should any attempt be made to reduce the piles, as later it will cause needless pain and is certain to fail. The treatment is, as for all inflammation, by rest and warmth. The patient remains in bed, hot fomentations are applied, and a hot bath is taken night and morning. Liquid paraffin is given, but aperients are avoided. Ointments and suppositories are of no therapeutic value. The inflammation subsides in a week or ten days, and in four weeks a thorough examination is made to decide the future treatment, remembering that the attack will be followed by temporary improvement.

A so-called thrombosed pile, which is really a hæmorrhage from a ruptured external hæmorrhoidal vein, is a common complication. It is almost certain to be repeated on three or four occasions until the marginal veins are obliterated. The pain is sudden in onset, occurs during defæcation or straining, lasts for about five days, and is in proportion to the size of the hæmorrhage. If seen within twenty-four hours it is

best treated by excising an ellipse of skin under local anaesthesia and extruding the clot. If seen later, it should be allowed to subside, but there is some risk of ulceration of the overlying skin or of the development of an abscess. A skin tag is a common sequela.

Intense pain, occurring each time the bowels are open and lasting a considerable time, is generally due to a fissure. It is a frequent complication of prolapsing piles or of polypi and is found in the mid-line posteriorly. A fissure associated with piles is best treated by operation, when both can be dealt with at the same time. An anterior fissure in women is frequently due to the combination of piles and a torn perineum. In such cases the fissure will not heal permanently until the perineum has first been repaired.

CONCLUSIONS

A patient with piles is suffering from a progressive disease, and drugs, ointments and suppositories cannot delay or alter its course. Palliative treatment suffices in the very early stages. Later a reasonably accurate estimate of the prognosis following injections can be given, and the severe cases can be offered a practically certain cure by operation. Complications are common in the more advanced stages and with a few exceptions must be treated before the piles. The treatment of piles is much more successful than that of diseased veins in other parts of the body.

Reviews

A HISTORY OF TROPICAL MEDICINE: BASED ON THE FITZPATRICK LECTURES—DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, 1937-38.—By H. Harold Scott, C.M.G., M.D., F.R.C.P. (Lond.), D.P.H., D.T.M. & H. (Camb.), F.R.S.E. Volumes I and II. Edward Arnold and Company, London. Pp. xix plus 648 in volume I and Pp. iv plus 649 to 1165 in volume II. Illustrated. Price, 50s. for two volumes

Each year it becomes more difficult to justify the separation of the study of tropical medicine from that of general medicine. There is no exact definition of a tropical disease, and the choice of which diseases shall and which shall not be considered tropical is purely arbitrary. Whilst temperature plays an important part in determining the distribution of diseases throughout the world, there are many other more important factors and the state of general sanitation is one of the most important; many diseases that are now looked upon as tropical diseases, because to-day they seldom occur outside the tropics or sub-tropics, are really only diseases of sanitariously backward countries and would disappear from the world altogether if sanitary standards of the more advanced countries were to become universal.

A history of tropical medicine is to a great extent a history of one particular phase of scientific medicine, the parasitological phase, whose most active period was from the time of Robert Koch's discovery of the tubercle bacillus to the days of the study of community nutrition, when parasitology began to fall back into its proper place in the more comprehensive science of hygiene.

A medical historian of the future might well devote a section, a large one, to 'the rise and fall of tropical medicine, from Patrick Manson to Robert McCarrison'. We believe that it will be looked upon as a great period which had very important reactions on medical science in general. It demonstrated in a most dramatic manner what could be achieved by research; its brilliant successes in the chemotherapy stirred into activity the chemist and the medical investigator in temperate climates, and its demonstration of the gross results of dietary deficiency fired the imagination of

the biochemist and physician to an intensive study of the results of minor deficiencies which is tending to dominate the medical outlook of the present day. Its decline—as a separate science—which we foretell, will be due to its own successes; in many instances life in the tropics is now as healthy as that in temperate climates and the lines of distinction between the diseases of the different zones is becoming hazier year by year. In other words its decline is no decline but a mergence into general medical science.

Whilst it may possibly be true that history is best written in retrospect, the contemporary historian has an important duty to perform, for the sake both of the present and of future generations and if the picture he paints is not such a well-balanced and well-proportioned masterpiece its details are certainly truer.

It was quite time that the history of tropical medicine was recorded and who was better qualified to do this, by virtue of his abilities as a writer and on account of his unique opportunities than Dr. H. H. Scott. Dr. Scott, who worked in the tropics for many years, has for the last 10 years been associated with the Tropical Diseases Bureau of which he is at present the director—and thereby editor of the *Tropical Diseases Bulletin*, that most useful of all publications to the worker in the tropics—and has therefore had his finger on the pulse of tropical medicine during the latter half of its most active period.

Dr. Scott traces the beginnings of tropical medicine to a period much earlier than we have suggested and gives numerous extracts from some of the earliest writers. These contain apparent flashes of intuition, the results of accurate epidemiological observations which, though ignored or forgotten in the early days of the parasitological era, are now explainable, but for the most part these writings provide amusing reading. Dr. Scott, however, warns us that our beliefs and theories may appear equally absurd to subsequent generations of readers. Perhaps the characteristic feature of these early writings, such as those of Chisholm, is their dogmatic statements which obviously rest on the barest basis of experience on the part of the writer, which experience he seldom troubles to quote, and the fantastic theories which are not usually

expressed as theories but as facts. Though our deductions may appear ridiculous to future generations, surely our data will be of some value, if in the morass of modern literature it will be possible to find them.

The author describes the parts played by the services, the colonies, and India in the development of tropical medicine, in separate chapters, and then takes up the more important diseases one at a time. As regards space allotment malaria and yellow fever divide the honours with a hundred and sixty odd pages each. The last four chapters are on the Suez canal, the Panama canal, the slave trade and disease, and finally a series of brief biographies of 15 outstanding figures in tropical medicine, from Garcia da Orta (1490) to Ronald Ross (1857 to 1932). There is a select bibliography in which books only are included, an authors' index (which allows tropical workers to decide immediately if the book is a good one or not!) and a comprehensive subject index.

We awaited this work impatiently and with high hopes, and we were not disappointed. The history of medicine is infinitely enriched by the addition of these two volumes.

TEXTBOOK OF MEDICAL TREATMENT.—By Various Authors. Edited by D. M. Dunlop, B.A. (Oxon.), M.D., F.R.C.P. (Edin.), L. S. P. Davidson, B.A. (Camb.), M.D., F.R.C.P. (Edin.), M.R.C.P. (Lond.), J. W. McNee, D.S.O., D.Sc., M.D. (Glas.), F.R.C.P. (Lond.). 1939. E. and S. Livingstone, Edinburgh. Pp. xx plus 1127. Illustrated. Obtainable from Butterworth and Company (India), Limited, Calcutta. Price, Rs. 16-12

To add another book to the already overcrowded medical library is undertaking a grave responsibility. The reasons for the editors' decision to undertake this work are given in the preface. These include a general criticism of textbooks on medicine, which is unfortunately as true as any general criticism can be; this is, in the main, that useless or obsolete forms of treatment are copied from textbook to textbook, that when more than one form of treatment is mentioned there is no indication as to what should influence the practitioner's choice, and that these books abound with vague statements, such as 'vaccines may be tried'. Further, they consider that the space allotted to treatment in textbooks is usually inadequate. With a group of very able and practical contributors the editors have set forth to put matters right, and we have no hesitation in saying that they have to a great extent succeeded.

The subject-matter is divided into the following chapters:—Infectious diseases; septicæmia and erysipelas; tuberculosis; common diseases of the skin; venereal disease; common tropical diseases and helminthic infections; some common disorders in infancy and early childhood; industrial diseases; metabolic diseases—diabetes, obesity; deficiency diseases; diseases of the ductless glands—thyroid; suprarenals, etc.—diseases of the blood, spleen and lymphatic glands; diseases of the alimentary canal; diseases of the liver, gall-bladder and biliary tract, pancreas and peritoneum; diseases of the heart and circulation; diseases of the blood vessels and limbs; diseases of the nose, throat and ear; diseases of the respiratory system; renal diseases; chronic rheumatic diseases and diseases of bone; diseases of the nervous system; psychotherapy in general practice; technical procedures and oxygen therapy.

Each chapter is written by an individual or more often two contributors. The quality of the contributors is even and, in the chapters we selected for special study, the principles laid down in the preface have been observed and the faults which were noted as occurring in other textbooks, as far as possible, avoided. However, the expression 'may be tried' did appear occasionally.

The chapter on tropical diseases is left in the experienced hands of Colonel Greig. Most of the treatment he advocates is sound and up to date, an exception being that he gives preference to thymol in the treatment of ancylostomiasis, for the very poor reason that a

particular worker who has had considerable experience in the treatment of this infection considers it the best treatment. He does not mention that this particular worker retired from the tropics 20 years ago, and has obstinately refused to see that since his day more effective, more safely-administered, and cheaper drugs have been introduced.

In the section on anaemia Professors Davidson and Fullerton naturally start with a classification: this is the classification that recent work on the subject has indicated and it certainly simplifies treatment. The subject is dealt with thoroughly but never redundantly in about 70 pages.

It is a book that we can strongly recommend to the practitioner in this country. The price is reasonable, and both quantitatively and qualitatively very good value for the money.

TREATMENT OF SOME COMMON DISEASES (MEDICAL AND SURGICAL).—By Various Authors. Edited by T. Rowland Hill, M.D. (Lond.), M.R.C.P. (Lond.). 1939. E. and S. Livingstone, Edinburgh. Pp. xv plus 398 with 90 illustrations, including several in colour, and many x-rays. Price, 15s. Postage, 6d.

THE conception of this book was a very pretty idea; all the contributors are members of the honorary staff of the Southend General Hospital. If its publication serves as another bond of harmonious union between these heterogeneous London (mostly) consultants, the book will at least have served one good purpose. Perhaps, if we say that we don't think very much of it and that the medical bookshelf would have been less overcrowded, but otherwise little poorer, had this book never been published, we can provide them with another common cause. It is a book that supplies no particular want, and fits into no place in one's library. Any two numbers of a medical paper such as the *Practitioner* will give one as good a selection of articles as appear in this book, with the added advantages that they have been subjected to experienced and masterly editorship and that should you want to refer to them again you know where to look for them.

The editor's apology in the preface is unconvincing, as well as being curiously expressed.—'Books devoted to the description of modern methods of treatment and designed for the general practitioner have shown a tendency rapidly to multiply in the last few years'. (It is better to deliberately split an infinitive than to avoid clumsily splitting one, as Fowler might have said.) 'We have felt that many of these volumes, unquestionably meritorious and valuable, have been forced to compress much subject-matter into a restricted compass.' And into one chapter of 23 slender pages, he himself (or should we blame the volume) then attempts to compress the whole subject of anaemia—classification, symptomatology, and treatment—and he doesn't hesitate to include such rare diseases as Albers-Schöberg's, Niemann-Pick's and Hand-Schüller-Christian's in his scope.

The book contains a number of articles that are 'unquestionably meritorious and valuable'.

MEDICAL TREATMENT IN GENERAL PRACTICE WITH RECENT ADVANCES.—By D. R. Dhar, M.B., D.T.M. (Cal.), M.R.C.P. (Lond.). 1939. Published by Monica Dhar, 36, Chowringhee Road, Calcutta. Pp. xiii plus 596. Price, Rs. 10-8 (Indian) or 22s. 6d. (Foreign). Obtainable from D. M. Library, 42, Cornwallis Street, Calcutta

In his excellent foreword to this book Colonel R. N. Chopra writes 'The greater part of the space in books on medicine is generally devoted to the description of the aetiology, diagnosis and symptomatology of a disease and the treatment is only perfunctorily dealt with. A complete modern treatise on treatment, keeping in view the conditions existing in India, is yet to be written. The general practitioner has, therefore, always felt the want of a book dealing adequately with treatment, and this book is intended to supply the want'.

He adds, 'the inclusion of Indian preparations in the description of the diet given by this author should greatly appeal to medical practitioners, particularly in Bengal'.

In this book of nearly 600 large pages, about 90 per cent of the space is devoted to treatment. The writer has displayed his vast knowledge of recent medical literature and has provided for the student and practitioner a mine of information on medical treatment.

Cholera, for example, is given 27 pages and 24 of these are on the subject of treatment. Comparing this with other books that the reviewer happens to have in his desk, he finds that a textbook on general medicine of 1200 pages devotes 3 page to the treatment of cholera, and two standard books on tropical medicine four and nine pages, respectively. So that the author's claim that he lays special emphasis on the most important aspect of medicine, namely treatment, is fully justified.

We have, however, a few criticisms. The author suffers from the besetting weakness of Indian practitioners and teachers, a weakness, let us add, which many have entirely overcome; he does not correlate theory and practice, and he does not really believe a great deal of what he reads and teaches. He quotes the remark that 'the introduction of the full diet in the therapeutics of typhoid fever is the greatest contribution of all time toward the control of the malady'. What he himself says about diet is 'During the height of the fever the patient does not like to take any food except liquids. Glucose water, butter milk, fruit juice, drinks sweetened by lactose, may be given in four to eight ounces every two to three hours. Though the usual requirement of about 3,000 calories for an average young adult during the febrile stage can not be kept up [sic] here, yet for all practical purposes if given only *plenty of liquids* at the height of the fever even with extreme loss of appetite, the patients do well'. Then his conscience pricks him and he adds 'But during the early or later stages with some desire for food yet left, besides milk sweetened with glucose, one can easily give boiled smashed potatoes, with half-boiled egg or milk, or broth or soups. Boiled soft rice with milk and egg in the form of a pudding is a very palatable form of diet liked by most young patients'. He becomes even more bold and adds boiled fish and soft bread and butter. He however repeatedly gives warnings, such as, 'care should be taken to see that too much diet is not given, as this may conduce to diarrhoea'. The net result is probably that his patients get about 600 calories during the 'height of the fever' which may be for three or four weeks. He may be quite right, but if he believes in the low-calorie diet why not say 'the modern teaching about a high-calorie diet is not applicable in this country and I don't believe in it'.

We are frankly disappointed in his paragraphs on dietary suitable for Indian subjects. Most of them might have been taken directly from English or American textbooks with the occasional addition of an Indian fruit.

Wasn't it Lord Fisher who said 'Never withdraw, never apologize'? We might add another dictum 'Never print an *errata* slip'. It does no good to draw the attention of the reader to the fact that you have discovered, or someone else has pointed out to you, that 'metallic' is not spelt 'metalic', or that the printer has dropped an 'l' out of flatulence, or inserted an 'n' in 'exposure', especially when there are similar mistakes on every page.

However, we repeat, the book is a mine of information on the subject of medical treatment.

THE RELIEF OF PAIN: A HANDBOOK OF MODERN ANALGESIA.—By H. Balme, M.D. (Durh.), F.R.C.S. (Eng.), D.P.H. (Lond.). 1939. Second Edition. J. and A. Churchill, Limited, London. Pp. xvi plus 399. Price, 12s. 6d.

PAIN is the dominant symptom for which a large number of patients seek medical aid, and the problem of relief of pain due to various ailments is constantly

before the medical practitioner. The book under review is meant to help the practitioner in alleviation of pain of the suffering patient.

The book is divided into four parts: I. The problem of pain, II. General and systemic pain, III. Regional pain, and IV. The therapeutics of analgesia. The author has discussed the question as to what pain really is, its physiology, the physical phenomena associated with pain, its varieties, and then how an investigation of a painful affection should be carried out. The author has emphasized the importance of a thorough investigation, apart from which no satisfactory or scientific relief can ever be devised. He has next considered how the different diseases that give rise to general and systemic, or regional, pain have to be treated, particularly from the point of view of relief. Each section has been dealt with in adequate detail and in an eminently practical way. The chapter on prevention of pain stresses how we can and should examine and handle injured tissue, set fractures, dress painful wounds, and conduct such minor surgical procedures, painlessly. This chapter should be read by every young dresser, casualty officer, and general practitioner. The last part of the book deals with the therapeutics of analgesia, the different physiotherapeutic measures and analgesic drugs that are employed for relief of pain.

The book is admirably written and its popularity is apparent from the fact that it has reached the second edition within two years and a half of its first publication. The book will be found useful by general practitioners and specialists alike.

P. C. S. G.

ANÆMIA IN PRACTICE: PERNICIOUS ANÆMIA.—

By W. P. Murphy, A.B., M.D. 1939. W. B. Saunders Company, Philadelphia and London. Pp. 344. Illustrated. Price, 22s. 6d.

THIRTEEN YEARS ago, Drs. G. R. Minot and W. P. Murphy published a paper in the *Journal of the American Medical Association* describing the effect of liver diet in pernicious anæmia. This was a clinical study, but the results were striking enough to attract a considerable amount of attention, not only of clinicians but of laboratory workers as well. The immediate direct result was a revolutionary change in the treatment of pernicious anæmia with a very great improvement in the prospects of the pernicious anæmia patient, and an even more important indirect result has been a great revival in the study of hæmatology which has led to a more rational classification of the anæmias and to a much better understanding of disorders of the blood, generally.

Dr. Murphy has decided to present his knowledge on this important subject in book form, and a book by so distinguished an author on the subject in which he has made his name cannot be ignored.

Our main criticism of this book is of its title; this is either meaningless or misleading. It seems either to imply that the anæmia one encounters in practice is always pernicious anæmia, which is absurd, or it suggests that the book is a general one on anæmia in practice, including pernicious anæmia, which it is not. Actually, it is a book on pernicious anæmia with a few introductory chapters on anæmia in general. Four-fifths of the book are devoted to pernicious anæmia, the remaining fifth is divided between hypochromic anæmia and normocytic anæmia; tropical macrocytic anæmia has found no place in the book and the section headed 'nutritional anæmia' refers to the anæmias of scurvy, of thyroxin deficiency, and of general starvation only.

The clinical chapters on pernicious anæmia are good and one must listen with respect to the teaching of a pioneer in the present-day liver treatment of this disease.

In this country where the disease is rare, only to those who take an academic interest in pernicious anæmia can we recommend this book,

THE HEART SOUNDS IN NORMAL AND PATHOLOGICAL CONDITIONS.—By O. Orlas, M.D., and E. Braun-Menendez, M.D. 1939. Oxford University Press, London and New York. Pp. xx plus 258. Illustrated. Price, 15s. Obtainable from Oxford University Press, Bombay and Calcutta

INVENTION and perfection of different instruments of precision such as the stethoscope, the sphygmomanometer, the electro-cardiograph, the orthocardiograph, etc., have been landmarks in the path of progress of cardiology. Each invention has given an impetus to further study that has led to important contributions to the subject. The phonocardiograph, the most recent of the instruments of precision, provides the means of obtaining a faithful graphic record of heart sounds.

This excellent monograph tells us all about the valuable results that have been obtained with the phonocardiographic method of exploration of heart sounds.

The book is divided into three parts: the first being the general introduction and methods of studying the sounds, the second deals with the heart sounds in normal conditions, and the third with the heart sounds in pathological conditions. In the first part, the authors have described the gradual evolution of knowledge of heart sounds; when it was first recognized, how its presence was first denied and how with the advance of knowledge the denial came to be regarded as 'a shameful testament of human stupidity', and finally how the art of auscultation of heart sounds was developed by the masters like Laënnec, Potain, Huchard, Skoda and others. Gradual development of the methods of graphically recording the heart sounds has been described and the subject of heart sounds, its physical and physiological aspects have been discussed in considerable detail. The technical details of phonocardiography have been fully described. The chapters dealing with the normal heart sounds show the result of analysis of heart sounds by the phonocardiograph. The different components that make up the sounds have been identified and their characteristics fully studied.

The character and mode of causation of the third heart sound and the auricular sounds have been demonstrated. In the chapter dealing with the heart sounds in pathological conditions, the graphical records of the heart sounds in the different valvular diseases, pericarditis and other cardiovascular abnormalities have been demonstrated. Phonocardiographic studies of the subject of gallop rhythm has yielded valuable results and the different modes of production of gallop rhythm have been clearly demonstrated.

The limitations of auscultation as a means of investigation are generally admitted. The graphic method of registration has not only provided us with means of objective and quantitative analysis of heart sounds, but it has definitely led to considerable advance in the knowledge of heart sounds in normal and pathological states.

The authors have studied the heart sounds graphically for a number of years and have made valuable contributions to the subject. Their monograph is an admirable exposition of this relatively new branch of cardiology.

The illustrations and graphical records are excellent: the latter represent the result of a perfect technique arrived at by years of painstaking research.

The book should be in the library of every cardiologist.

P. C. S. G.

CARBON MONOXIDE ASPHYXIA.—By Cecil K. Drinker, M.D., D.Sc. 1938. Oxford University Press, London and New York. Pp. xx plus 276, with 40 figures and 21 tables. Price, 25s. Obtainable from Oxford University Press, Bombay and Calcutta

THIS is a monograph written for the benefit of those who have to face the various risks associated with carbon monoxide asphyxia, especially in connection with industrial concerns. As man is progressing with civilization he has to invent newer and better machines

for the amenities of modern life some of which are not without their attendant evils. The writer, as a practical man, does not condemn these modern advances because they are associated with some risk to life, but has tried to cope with the hazards when they arise and to minimize their incidence as far as practicable. He states that 'there would no doubt be some 40,000 fewer deaths per year in the United States if automobiles were prohibited and we went back to the horse-drawn age', but such a wholesale restrictive measure would only serve as a retrograde step and would not solve the problem in practical life. It is the duty of modern man, the author opines, to learn to control the danger, but not to abandon the machine. The use of gas, of gasoline, of oil and of coal is part of the daily life in modern civilization throughout the whole world, and carbon monoxide is the companion of the use of all of these. As this use cannot be abandoned, Professor Drinker tells us in this monograph how best we can avoid the dangers and cope with abnormal situations when they have arisen.

The writer has begun with a discussion of the physiology of respiration as it is affected in carbon monoxide asphyxia. In the next two chapters, the effects of the noxious gas on the different organs of the body and the symptoms and signs of poisoning are described in detail. The common sources of carbon monoxide as found in cases of poisoning have been mentioned and some statistics on the subject have been given. One finds a good deal of interesting and useful information under this heading. For instance, very few of us know the large number of fatal accidents due to inhalation of exhaust gases from automobiles and from gas heaters and gas leaks. In our tropical climate this is not very dangerous but in temperate climates where there is no adequate ventilation the risk is indeed enormous. The pathology of the condition has been discussed in detail after which comes the signs and symptoms of chronic poisoning. In this connection the writer suggests that a physician should always bear in mind the probability of chronic carbon monoxide poisoning whenever he encounters mysterious conditions of ill health in a group of persons all subjected to the same environment. In discussing the treatment of the condition, the author considers that the most important factor for lessening the incidence of the danger is the education and propaganda work by intelligent inspectors. In acute poisoning, early resort to artificial respiration and inhalation of a mixture of 93 per cent oxygen and 7 per cent carbon dioxide are the sheet-anchor. The author has also very ably deprecated the use of drugs and particularly the use of blood transfusion in a case of acute carbon monoxide asphyxia. The last chapter which has been written by Dr. Julius Sendroy, the Professor of Chemistry of the Loyola University, Boston, Mass., contains a complete and useful survey of the methods of analysis commonly employed for the detection and estimation of carbon monoxide in air and in the body fluids. An exhaustive bibliography will be found invaluable to those who are interested in the subject.

Professor Drinker with his vast experience and painstaking study has written the subject-matter in such an authoritative manner that the reviewer regrets he cannot find points for criticism. But there are three points to which the writer's attention may be drawn. The first is in connection with the arrangement of some of the chapters. After describing the symptoms of acute poisoning, the reader is suddenly diverted to what constitutes harmful exposure, sources of the gas and the pathology, after which the chronic poisoning has been taken up. Moreover, after discussing the effects of carbon monoxide on the different tissues of the body in the second chapter, the author has gone on to reiterate the same facts in the chapter on pathology. There is certainly an opportunity for rearrangement and modification of the material. The second point relates to the language. In some places, the language used by the writer is so unorthodox in nature that even a reader with great patience and forbearance will feel it difficult to persevere with his above virtue. A few examples will suffice; 'The

patient has gotten into an equilibrium'; 'of the individual who has been downed abruptly'; 'the legs began to become oedematous'; 'this carbon dioxide-rich blood', etc., etc. The last but not the least important point is the cost. A book of 276 pages, with a few line drawings only, and printed in the most usual way, on carbon monoxide asphyxia costs 25 shillings! Few readers will be able to afford this high price.

The book is undoubtedly a very good one and we commend it to engineers, insurance people, men handling compensation for accidents, safety directors and teachers of safety, lawyers and employees of utility companies. They will find in this book answers to many riddles without making the answers more confusing than the riddles.

M. N. D.

SEX AND INTERNAL SECRETIONS: A SURVEY OF RECENT RESEARCH.—Edited by Edgar Allen. Second Edition. 1939. Baillière, Tindall and Cox, London. Pp. xxxvi plus 1346. Illustrated. Price, 54s.

Endocrinology is a subject which has been making gradual advance for some time past; recently, however, the advance has been made with such speed, and the data accumulated therefrom have been brought to light with such bewildering rapidity that increasing difficulty was felt in evaluating some of the conflicting evidence which had gathered round the subject. With the object of surveying the progress of research on the problem of sex and internal secretions, the Bureau of Social Hygiene, New Haven, Connecticut, initiated a systematic programme of research on the fundamental problems of sex, under the administrative guidance and the team work of a committee appointed by the National Research Council, under the able editorship of Dr. Edgar Allen. The present volume, which appears to be an eminently useful and exhaustive survey and digest on the subject of the relations of the internal secretions to the phenomena of sex and reproduction, is the second edition which has followed in the wake of its predecessor in a thoroughly revised form within a period of five years. This revision was essential, especially in view of the fact that endocrinology of the sex function has been enriched by new experimental evidence, particularly in the biochemistry of the male and female hormones.

The book is primarily intended for those who are either interested or actually engaged in research work in the intricate problems of sex endocrinology. It is by no means a treatise intended to give general information on sex problems and hence, for a thorough understanding of the technical nature of the subject-matter of the book, a fair amount of biological background is necessary, particularly in embryology. The book deals with the most important recent researches on the problems of sex and as such will prove valuable to those who are engaged in investigations thereon or to those who are casting about for promising problems for investigation.

The book is divided into five major sections, each of which is again sub-divided. The contributors form a group of authors, each of whom has written on his own chosen field of interest.

The first section of the book deals with the biological basis of sex and includes sub-sections on the embryonic development of sex, modification of development of sex in lower vertebrates and in mammals, relation of genic and endocrine factors in sex, etc. The next section deals with the physiology of sex glands, germ cells and accessory glands and includes sub-sections on the biology of the testes, endocrine functions of the ovaries, some of the endocrine functions in pregnancy, etc. The next section, a highly important one from the point of view of the recent researches on sex problems, deals with the biochemistry and bioassay of androgens, oestrogenic compounds, corpus luteum progesterone, etc. The section which follows deals with the hypophysis and the gonadotropic hormones of blood and urine in relation to the reproductive system. It deals with such problems as the effect of the pituitary on the

gonads, the follicle stimulating and luteinizing hormones of the anterior pituitary, etc. The last section of the book deals with additional factors in sex functions and endocrine applications in man such as the relation of the thymus and pineal glands to the genital function, the relation of the vitamins to the sex glands, the sex drive and the sex functions in man.

The book gives a fairly exhaustive account of the scientific foundation on which our present knowledge of sex glands has been built up. The addition of an exhaustive bibliography at the end of each of the sub-sections of the book is a special feature and will be an invaluable guide to those who wish to amplify their knowledge on the subject. We have no hesitation in saying that the book is a valuable contribution to our knowledge on the subject and should prove to be a standard book of reference to those engaged in the problems of sex and internal secretions.

J. P. B.

PICTORIAL MIDWIFERY: AN ATLAS OF MIDWIFERY FOR PUPIL MIDWIVES.—By Sir C. Borkoley, M.A., M.C., M.D. (Cantab.), F.R.C.P. (Lond.), F.R.C.S. (Eng.), Hon. M.M.S.A., F.C.O.G. Third Edition. 1939. Baillière, Tindall and Cox, London. Pp. xii plus 166. Price, 7s. 6d.

In this third edition some new figures have been added and others deleted. The main new feature is the coloured illustration of the foetal circulation. This is a welcome addition and the use of colour has certainly simplified the subject, but we have seen black and white sections of the placenta which are easier to follow than the coloured one shown here.

This book will prove as useful to the medical student as to the student midwife and we can strongly recommend it to both, as well as to those who have to teach them.

CÆSAREAN SECTION—LOWER SEGMENT OPERATION.—By C. McIntosh Marshall, F.R.C.S. (Eng.). 1939. John Wright and Sons, Limited, Bristol. Pp. vii plus 230 with 2 plates and 107 illustrations. Price, 21s.

THIS little book is concerned entirely with the lower uterine segment operation of Cæsarean section. It starts with an interesting historical account of the evolution of Cæsarean section, and all the various operations connected with this procedure are enumerated.

However, as is natural in this book, it is the lower segment operation which is the only one described in detail.

The operation is reviewed from every angle, and the description is supported with a complete statistical list of the results of the author's own cases, and an extensive research into contemporary literature.

The author is to be congratulated on the extreme clearness with which he has described the operation, and for the wealth of excellent diagrams which makes it possible for the reader to follow every step with ease.

The indications for adopting the lower segment operation and the contra-indications to this choice together with its dangers and difficulties are well described and wise advice is given. Not the least interesting chapter is that which is devoted to the choice of the anaesthetic, the advantages and disadvantages of all the common anaesthetics being weighed in the balance, with the result that Mr. Marshall favours spinal anaesthesia as his first choice, and local sometimes re-inforced with ether or gas and oxygen as his second. In his experience, ether, chloroform, or the A. C. E. mixture tend to cause excessive hæmorrhage as they relax the uterus.

We suggest that this little book should be on the shelves of every specialist in obstetrics.

MENSTRUAL DISORDERS: PATHOLOGY, DIAGNOSIS, AND TREATMENT.—By C. Frederic Fluhman, B.A., M.D., C.M. 1939. W. B. Saunders Company, Philadelphia and London. Pp. 329. Illustrated. Price, 22s. 6d.

ALL practitioners who have to treat gynaecological cases will find this work by Professor Fluhman to be of much value and interest.

The author deals with that important, and often most trying, physiological process of menstruation from every angle—historical, normal, pathological, diagnostic, and therapeutic.

The information is right up to date and gives the present conception of female sex hormonology which, though still largely in experimental stages, has an undoubted therapeutic future and which must be studied by all who treat women's ailments.

The book is well bound, agreeably printed, has a large number of clear photomicrographs, and useful diagrams. At the end of each chapter, there is an ample list of references to other works.

This is a volume which will repay study and which will throw much light for the practitioner on a considerable, and often difficult, branch of gynaecology—menstruation and all its disorders.

K. S. F.

A TEXTBOOK OF SURGERY.—By American authors. Edited by Frederick Christopher, B.S., M.D., F.A.C.S. Second Edition. 1939. W. B. Saunders Company, Philadelphia and London. Pp. xxiv plus 1695. Illustrated. Price, 42s.

THIS interesting book, though arranged in the form of a textbook, really consists of a collection of papers by American surgeons, purporting to cover the whole field of general surgery.

The 1695 pages of text are shared by no less than 188 writers, of whom a few have contributed less than two thousand words each.

No doubt this is what makes the book so attractive; every section has an air of freshness, and every writer has taken pains to present the latest ideas to be found in the literature—or at least in the American literature.

Where so many excellent features are to be found it is unprofitable to make a thorough commentary on any one section. But the portions devoted to orthopaedics, diseases of bone, and allied subjects deserve special praise. The conditions under which man lives and works to-day have given rise to numerous new pathological conditions, especially in the skeletal system, and the student will find all the important ones described in this book.

While heartily recommending the book to the medical profession, its suitability for the undergraduate student is open to question, because the very features which make it so brilliant tend to detract from its value as a book of reference for candidates for the qualifying examinations. There is a wide variety of style and method of presentation; a lack of collaboration and synopsis which makes the text indigestible. Some contributors give dozens of references to the literature, while some—more merciful—give none. Some sections are prefaced by anatomy, and some are not; and in several sections the clinical and pathological descriptions are skimmed in order to present some new fad of surgical technique. But these are but slight roughnesses which are sure to be smoothed out in future revisions; and the second edition, which is now presented, should go far to enhance the good reputation the book has already earned.

W. McN. N.

TEXTBOOK OF GENERAL SURGERY.—By W. H. Cole, M.D., F.A.C.S., and R. Eiman, M.D. Second Edition. 1939. D. Appleton-Century Company, Incorporated, London. Pp. xxviii plus 1031. Illustrated. Price, 40s.

THIS is the second edition of a textbook for students, the subject-matter of which is based on the courses of lectures on surgery delivered at the Washington University School of Medicine. On this foundation

the authors have built a thoroughly well-balanced and readable book.

There have been numerous minor revisions and additions in the new edition, directed chiefly towards keeping the text abreast of recent advances in surgery. They will be of more value to the 'advanced' than to the 'elementary' student; and incidentally one supposes that it is for the benefit of the former that such exhaustive bibliographies adorn certain sections.

The book is arranged along the usual lines; a number of chapters on pathology, bacteriology, technique and the like precede the chapters on regional surgery. The text is interspersed with many good illustrations, of which the photomicrographs and skiagrams are exceptionally fine.

Students and practitioners desiring a sound and comprehensive surgical textbook at a moderate price would do well to give this book their close attention when making their choice.

W. McN. N.

THE CLINICAL DIAGNOSIS OF SWELLINGS.—By C. E. Corrigan, B.A., M.D., F.R.C.S. (Eng.). 1939. Baillière, Tindall and Cox, London. Pp. viii plus 313. Illustrated. Price, 18s.

THIS is one more book dealing with the elicitation of physical signs in clinical surgery but it is restricted to the investigation of swellings. As there is no dearth of excellent handbooks on the subject, doubts may be expressed about the necessity of another book of 313 pages. The author explains that it is intended to be used as a 'companion to clinical practice' rather than as a textbook to prepare one for clinical encounters.

There are twenty-six chapters in this book, dealing firstly with general considerations and finally with the different regional swellings. This is a good book and the principle which is followed is commendable. 'Direct your questions to the swellings themselves, rather than to the patient, and the answers received will be more concise, less circumstantial and more dependable.'

The printing, get-up and illustrations are of the usual standard. The reproduction of photographs has been eschewed in favour of line drawings which, the author claims, serve the more desirable purpose of translating clinical manifestations into terms of anatomy and pathology. A useful index is appended. The insertion of brief biographical notes at the end of each chapter adds to the value of the book.

P. N. R.

INFECTIONS OF THE HAND.—By L. R. Fifield, F.R.C.S. (Eng.). Second Edition by P. Clarkson, F.R.C.S. (Eng.). 1939. H. K. Lewis and Company, Limited, London. Pp. xii plus 167 with 57 illustrations, including 8 plates (2 coloured). Price, 9s.

THE second edition of Fifield's *Infections of the Hand* is sure to receive the same welcome which was meted out to its predecessor. Mr. Clarkson, in editing a popular book, has done his work well. Every chapter has been practically re-written and special chapters have been added on the treatment of wounds of the hand, on special infections and on insurance aspects and prognosis.

In the treatment of infections, chemotherapy rightly deserves special mention. Of the sulphanilamide derivatives, only M. and B. 693 has been mentioned. This drug appears to be of particular efficacy in pneumococcal infections, but it is certainly not the most potent medicine in streptococcal infections. Prontosil red, the original preparation, is still supreme in its therapeutic effect in cases of streptococcal infection, particularly of the haemolytic type. There is no justification for the deliberate omission of the name of Prontosil.

The printing, get-up and illustrations are all very good. There is also a useful index.

P. N. R.

RELATION OF TRAUMA TO NEW GROWTHS: MEDICO-LEGAL ASPECTS.—By R. J. Bohan, M.D., Dr. Mod. (Borlin), F.A.C.S. 1939. Ballière, Tindall and Cox, London. Pp. xii plus 425. Price, 22s. 6d.

The rôle of an expert medical witness is at all times an unenviable one; it is particularly so when he is faced with the vexed question of the traumatic origin and development of new growths. Dr. Bohan has done a great service by writing this monograph which it is confidently expected will be of value not merely to the medical practitioner, but also to judges and lawyers in cases of litigation over compensation.

There are, altogether, thirty chapters in this book presenting a complete account of the subject with citations of leading cases and judgments. Many judicial opinions have been rendered in favour of the concept that trauma is an important causative factor in the origin of new growths. It is also frequently essential for the court to determine if the injury received was instrumental in the development of metastasis. The definition of trauma, from the medico-legal aspect, is not so easy as it seems. Current medical opinion concerning the effect of chronic irritation, single trauma, indirect injury and occupation cannot be said to have been sufficiently crystallized. Regarding the incidence of occupational carcinoma, the Federal Minister of Labour in Germany, commissioned Professor Dr. Otto Teutschlaender, of the Institute for Experimental Cancer Research in Heidelberg, to investigate the problem of occupational cancer. He suggested that the disability due to cancer resulting from trauma or irritation in workers while engaged in their usual occupations are to be classified under 'hazards of industry' and should be held equally compensatory with the disabilities due to injuries. The chimney sweepers' cancer is diminishing, but the incidence of carcinoma amongst aniline and tar workers, mule-spinners, shale-oil workers, and others, is certainly on the increase.

In a critical review Kolodny stated that there 'is strong evidence to support the view that in general, trauma may lead under certain predisposing conditions to osteogenic sarcoma', but the time interval as a factor varies considerably. In the case *Greeby vs. Phila Asbestos Co. et al.*, osteo-sarcoma of the femur was alleged to have followed injury, and compensation was awarded. The relationship of mammary carcinoma to trauma, the result of a blow, seems to have been placed on a legal 'cause and effect' basis by Handley in his report of a 'legally established case of traumatic carcinoma of the breast' (*Practitioner*, Dec. 1934). It is, however, to be regretted that legal opinion, as voiced in court decisions, while they add to established precedent, do not contribute to medical knowledge (Knox).

The printing and get-up of this book are very good, but there are many printing mistakes. The book is written in simple and elegant English but there are expressions with which we are not familiar; carcinoma of the male breast is said to be frequently produced by the 'constant irritation of a suspender* buckle riding over the nipple'. Nevertheless, we have much pleasure in recommending this book, which is likely to fill a long-felt want.

P. N. R.

AN INTRODUCTION TO CLINICAL PERIMETRY.—By H. M. Traquair, M.D., F.R.C.S. (Ed.). Third Edition. 1938. Henry Kimpton, London. Pp. xv plus 320 with 227 illustrations and 3 coloured plates. Price, 30s.

This is the third edition of this classical work by Dr. Traquair and makes a very welcome appearance. The procedure described in his method of visual field testing is both easy and satisfactory and known as the quantitative method of perimetry. This is essentially

[*Our reviewer has evidently had an English and not an American education. In America 'braces' are 'suspenders', and 'suspenders' are 'garters'.—EDITOR, I. M. G.]

associated with the name of Bjerrum who discovered that he could obtain more information by using the back of his consulting-room door than he could from the ordinary perimeter. This method has also been extensively used by Roenne who has demonstrated its value in the diagnosis of all ocular diseases in which perimetry is helpful.

The author points out that success in perimetry will not be attained by the use of complicated and expensive apparatus but by the study and application of simple principles. Not less essential is a knowledge of the visual path so that a correct interpretation can be made of the results obtained.

The book is divided into two parts. In part 1 the author describes the normal field of vision, perimetric instruments, methods of examination and the physiology of the visual field in relation to clinical perimetry. In part 2 he deals with applied perimetry in which he discusses the pathological field, the interpretation of changes in the visual field, the choroid and retina, glaucoma, the optic nerve, the chiasma, the supra-chiasmal pathway and the functional changes in the field of vision. There is also an appendix in which are described the isopters for white and colour in the normal field, the blind spot, the anatomy of the visual pathway, the uses of the perimeter and screen otherwise than in field testing and tables of tangents and degrees for use with Bjerrum's screen.

The third edition does not differ very much from the previous ones except that a foreword has been contributed by Mr. Norman Dott from the standpoint of the neurologist and neuro-surgeon and forty-eight new illustrations have been added.

The book is delightfully written, well illustrated and easy to follow and understand. It is a book which will be found essential to every medical man working in India who is interested in ophthalmology or neurology. The author is to be congratulated on his great work and every ophthalmologist and neurologist should be grateful to him for his helpful volume.

E. O'G. K.

REFRACTION OF THE EYE.—By A. Cowan, M.D. 1938. Henry Kimpton, London. Pp. 319. Illustrated with 172 engravings and 3 coloured plates. Price, 21s.

In this work the author has endeavoured to employ the theory of ophthalmic optics in such a way that clinical aspects would emerge logically and in orderly sequence from their bases of scientific facts. His experience has resulted from nineteen years of teaching in the Graduate School of Medicine of the University of Pennsylvania and over thirty years of practice in ophthalmology.

The book consists of some three hundred pages divided into nineteen chapters. He first deals with media, the propagation of light and with reflection and refraction of light from plane and spherical surfaces. He next deals with the characters of lenses and then in six chapters applies these factors to the human eye. These chapters consist of the normal static eye, visual acuity, aperture of the system, accommodation, ametropia, accessory effects of the correcting lens, methods for the determination of the refraction of the eye, the management and optical treatment of ametropia and finally there is a chapter on contact glasses and telescopic spectacles.

The author has succeeded admirably in what he set out to do and is to be congratulated on producing such an excellent book. The style is simple and the illustrations are excellent. It is hardly suitable for the student but will be found most helpful for medical men who are interested in ophthalmology and for whom we strongly recommend it.

E. O'G. K.

THE BASIC MECHANICS OF HUMAN VISION.—By R. Brooks Simpson. 1939. Chapman and Hall Limited, London (11, Henrietta Street, W.C.2). Pp. viii plus 228. Illustrated. Price, 12s. 6d.

The least that can be said about the book is that in it the author introduces a refreshingly new, if not

an altogether revolutionary mode of approach to the science of ophthalmology. Whether it is due to the innate conservatism of the medical profession in general or to the highly intricate nature of this particular branch of medical science, works on ophthalmology of this nature, in which the author dares to deviate from the beaten track, have been extremely rare, leaving aside of course publications by pseudo-oculists who claim to give us 'perfect sight without glasses'.

The author never asserts that glasses can be dispensed with altogether, but he insists that they are to be regarded as a means to an end. The sum of his assertion is that, in a patient born with normal infantile eyes, the refractive error in his visual mechanism must have been *ipso facto* subsequently 'developed', and it is his claim that this 'developed irregularity' is capable of being overcome by mechanical training (with aid of instruments depicted by the author) and as a corollary he holds that conditions secondary to primary mechanical irregularity are mainly capable of elimination by normalization of the action of the visual mechanism.

To this problem the author devoted a life-time of research and this book is the record of his painstaking and conscientious effort.

T. A.

'THE ETIOLOGY OF TRACHOMA'.—By L. A. Jullianelle. 1938. The Commonwealth Fund, New York, and Oxford University Press, London, Humphrey Milford. Pp. xv plus 248. Illustrated. Price, \$3.25. Obtainable from Oxford University Press, Bombay and Calcutta

THOUGH trachoma is undoubtedly one of the most important diseases in ophthalmological practice in India, comparatively little attention has so far been paid in this country towards the elucidation of the ætiological factors responsible for this disease. Commendable efforts have been made by the workers in various western countries to study the causative factors involved and the literature on the subject has grown to a voluminous extent during the last 10 years. Dr. Louis Jullianelle, Chairman of the Trachoma Commission of the Washington University, has done a great service to ophthalmologists by presenting in a handy little volume a clear and lucid summary of the important work done by himself and his co-workers along with a review of the whole subject of trachoma. There is little doubt that the book will be welcome to all those interested in the field, particularly to those who are engaged in research work.

The book is divided into ten chapters with introductory remarks at the beginning and a general discussion at the end. In these chapters the subject is treated with particular reference to epidemiology, causation, and infectivity of the disease. The rôle of the micro-organisms associated with the disease, the inclusion body, the relation of virus to trachoma, the purification of the infectious agent, the cultivability of the infectious agent in tissue culture and the various other properties of it—have all received detailed and adequate treatment.

According to the author the infectious agent of trachoma is 'a virus characterized by low infectivity, occasional filterability, marked tissue specialization, ineffectual immunogenic properties, slight propagative capacity, and sensitivity to deleterious agents. Whether the virus may be interpreted in turn as the inclusion body or more accurately the elementary form of the inclusion body remains to be proved although the evidence available at the present suggests this may be so'.

The book is well got up and the illustrations are beautifully executed. The bibliography is up to date and is grouped under topical headings. The book should find a place in the library of all progressive ophthalmologists and help in stimulating further research on this line.

T. A.

MEDICAL JURISPRUDENCE AND TOXICOLOGY.—By William D. McNally, A.B., M.D. 1939. W. B. Saunders Company, Philadelphia and London. Pp. 386. Illustrated. Price, 17s.

THIS excellent book fulfils a need. For several years now in the textbooks on forensic medicine there has been a steady contraction of toxicology. The authors write for medical men who have not specialized in toxicology and give them the merest indication of what their colleagues in toxicology do. This book gives details. Up-to-date information is also available on war gases, gases used in refrigeration, and a dangerous slimming drug, dinitrophenol. It could have been mentioned that dinitrocresol and dinitrothymol are also dangerous.

Information on topics other than toxicology is sound. Some of it forms a rare record indeed. That in America (U. S. A.) coroners usually are politicians with no legal or medical training, that in the larger cities the attachés of the coroner's office are frequently accused of accepting bribes or of demanding certain fees, that x-ray medico-legal 'rackets' exist, and that lawyers and doctors unite wilfully to deceive courts of justice, will come as eye openers to law-abiding citizens used to the British system of upholding law and order.

In the precipitin test for blood perhaps some of the controls are in excess of the actual requirements.

The narrative has become confused and erroneous in the description of methods of determining blood groups. On page 70, from line 7, 'and B' should be deleted. Groups I and IV on page 71, para 3, are really groups IV and I of page 70. Nomenclatures of Jansky and Moss have been mixed. It would be better to discard them altogether in the next edition in favour of O, A, B and AB. Inheritance of M and N is not given.

The Americanism arrests attention in a few places but is not confusing. Prescriptions, for instance, are 'filled'; certain 'physicians' are surgeons.

The book should be in the library of all interested in forensic medicine.

The paper, the printing and the binding are good. No printer's error arrests attention.

S. D. S. G.

SURGICAL APPLIED ANATOMY.—By Sir Frederick Treves, Bart. Tenth Edition, revised by L. Rogers, M.Sc., F.R.C.S., F.R.C.S.E., F.R.A.C.S., F.A.C.S. 1939. Cassell and Company, Limited, London. Pp. x plus 748. Illustrated with 192 figures including 66 in colour. Price, 14s.

FIFTY-SIX YEARS is a long life for a medical book: in its earliest days this book stood almost alone, now it has many rivals, but it still holds its own. It was originally written by Sir Frederick Treves and during its long career of nine new editions and twenty-two reprintings it has been revised by such well-known surgeons as Sir Arthur Keith and Professor Choyce. It is five years since the ninth edition was published; this has been very completely revised and largely rewritten to produce the present edition.

Considerable pruning has been necessary and obsolete surgical procedures have been omitted: this particularly applies to the special section, on the eye, ear, nose and throat, in which matter the author has received considerable help from his contemporaries.

It is a book which still fulfils well the purpose for which it was first written and we can strongly recommend it to the surgeon, and the would-be surgeon.

WHITE SETTLERS IN THE TROPICS.—By A. G. Price. Additional notes by R. G. Stone. (Special publication No. 23.) 1939. American Geographical Society, Broadway at 156th Street, New York, N.Y. Pp. xiii plus 311. Illustrated. Price, \$4.00.

THIS is an attempt to review as a whole the success or failure of white settlement throughout the tropical lands of the world and all aspects of the problem are considered, namely, climatic, medical, social, economic, etc.

The author has apparently acquired his experience as a tourist, albeit with the special object of enquiry into this problem, and not as a sojourner for any appreciable time in any localities. As a result he has mainly relied on the written and spoken words of all kinds of people, some recognized authorities and some obviously local 'celebrities' only, so that the book is a mass of contradictory opinions with little attempt to sort the wheat from the chaff.

After reading the book the reviewer felt he was where he was at the beginning regarding the subject of white settlement in the tropics as no constructive suggestions are put forward. One point emerges, however, and that is that it is no more possible to lay down rules for successful European settlement for the whole tropics than it is to outline a universal scheme of malaria control, as each country has its own special problems which differ from most of the others and this is probably the main reason that the book has failed, in the reviewer's opinion, to make a definite contribution to this difficult and important problem.

AIDS TO GYNÆCOLOGICAL NURSING.—By H. M. Gratton, S.R.N., S.C.M., D.N. (Lond.). 1939. Baillière, Tindall and Cox, London. Pp. xii plus 160. Illustrated. Price, 3s. 6d.

This small book, one of the 'Aids' series for nurses, is intended to give the student-nurse a short easily-understood summary of the rudiments of gynæcology. A brief account of fertilization, pregnancy, and its complications, labour and the puerperium, is included.

A summary of the common gynæcological conditions, operations, preparation of the patient for operation and examination, nursing procedures, such as douching and catheterization, are carefully set out.

Drawings of the common gynæcological instruments and lists of requirements for shaving patients, insertion of pessaries, plugging the vagina, and other nursing 'operations' are of much assistance to the probationer-nurse.

An omission which will be regretted by readers in this country particularly is that of mention of vesico- and urethro-vaginal fistulae and their treatment. These distressing conditions are of great importance to nurses in India.

We can recommend this useful book to nurses undergoing general training, and consider that it would be a suitable work for training of Indian nurses, if translated into vernacular.

K. S. F.

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES, NO. 233. 'APPENDICITIS: A STATISTICAL STUDY.'—By Matthew Young and W. T. Russell. 1939. Published by His Majesty's Stationery Office, London. Pp. 64. Price, 1s.

'The remarkable progress of many branches of medical science in recent years must be contrasted with the relatively slow advance in knowledge in other important branches of medicine. Outstanding among this latter group are diseases associated with various parts of the alimentary canal. In spite of the high incidence of such conditions as gastric and duodenal ulcer, appendicitis and colitis, we remain remarkably ignorant of their causes. Of clinical material for their study there is an unlimited supply and yet, in spite of this, advance in knowledge of their causation is almost negligible. This does not mean that medicine and surgery are not able to bring great relief to patients suffering from these diseases, but it does mean that we still know too little about the predisposing factors to devise effective methods of prevention. Literature dealing with these diseases is nowadays concerned almost entirely with discussion of technical methods of treatment, and inquiries into causation are rare, probably because suitable experimental methods of producing the conditions in animals, which would allow a close study of their aetiology, are not available.

The report under review is based on a detailed investigation of the mortality statistics of this and other countries and of the statistics of certain hospitals.

The object of the survey was to determine whether any useful information could be obtained from such data, as to the factors which may influence the mortality from the disease and account for its very common occurrence at the present day. The figures relating to the frequency of appendicitis not only confirm that it is very prevalent, but show that it has apparently been on the increase in recent years. There is evidence, moreover, to suggest that the increase is real, and not due merely to greater knowledge and skill in diagnosis; for instance, amongst the insured population of Scotland the annual incidence of appendicitis increased appreciably even between 1930 and 1935, although this was not accompanied by any upward trend in the general sickness rate. Nevertheless, the mortality rate from appendicitis has remained relatively constant during the last twenty years, while the case fatality rate has fallen considerably, no doubt largely owing to the improvements in treatment, and especially in surgical treatment, which have occurred during this period.'

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES, NO. 234. 'REPORTS ON BIOLOGICAL STANDARDS—V. VARIABLES AFFECTING THE ESTIMATION OF ANDROGENIC AND ŒSTROGENIC ACTIVITY.'—By C. W. Emmens. 1939. Published by His Majesty's Stationery Office, London. Pp. 71. Illustrated. Price, 1s. 3d.

'ŒSTRONE, one of the forms in which the Œstrogenic hormone is excreted in the urine during pregnancy, was chosen some years ago to form an international standard preparation for the determination of Œstrogenic activity. At that time it was the only form in which the hormone was readily obtainable in sufficient quantity. The introduction of this standard enabled a unit of activity to be defined for general acceptance, in place of a wide series of unrelated units, in terms of different animal tests, which had confused both scientific notation and medical practice. It is now clear, however, that attempts to use this Œstrone standard to determine the activities of Œstriol, another excretory form of the hormone, and of Œstradiol, a form in which it is internally secreted to perform its physiological functions in the body, are subject to a number of sources of fallacy; thus, the results vary considerably with changes in the animal species (rats or mice) used for the comparative test, or in the method of solution of the substances for injection, or in the division and spacing of the doses injected. The apparent activities of these different forms of the same hormone are further affected, to different degrees, by the augmentor influence of other substances present in the preparation under test. Under such conditions it will be clear that little more than a conventional value can be attached to comparative determinations, in relation to the Œstrone standard, of the apparent Œstrogenic activities of crude extracts from urine or tissues, containing the different forms of the hormone in unknown proportions, with unknown admixture of substances capable of influencing the result.

It is clearly important that such factors of uncertainty should be fully recognized, and their significance measured.

Whilst the results obtained are not encouraging, the report is an important one and should be read by all interested in, or working on, this important subject.

TRANSACTIONS OF THE MEDICAL COLLEGE RE-UNION. VOLUME II. TENTH SESSION (1938-39).—Published by Dr. P. K. Guha, Honorary Secretary, Medical College Re-union, Medical College, Calcutta. Pp. 230. Illustrated. Price, Rs. 2

A NUMBER of valuable scientific papers were read during the annual re-union of the present and past students of Calcutta Medical College. This volume of the 'transactions' contains the addresses and scientific lectures delivered during the tenth session of the re-union held in December 1938.

The journal is divided into five sections. The first section contains the presidential address, the speeches delivered during the opening ceremony of the exhibition, prize distribution, the principal's report and the annual report of the secretaries, besides an editorial. The next three sections are devoted to medicine, surgery, and midwifery, and the students' section forms the fifth and last section.

The sections containing the scientific papers include a number of articles that will be read with great interest and benefit by students and general practitioners alike. Technical details of some of the articles, *viz*, those on the typing of pneumococci, the quality of cod-liver oil, tissue culture, will be appreciated better by the specialists working on these particular lines than by medical practitioners.

Some of the articles deserve special mention as being particularly valuable and instructive. In the section of medicine the articles on clinical heart disease, pellagra, sub-acute bacterial endocarditis are of great practical value. The articles dealing with the treatment of common skin diseases could not fail to interest the practitioner in this country where skin diseases are so common. The observations on a case of congenital heart disease (Lutembacher's disease) with heart block and auricular flutter will prove interesting to all

cardiologists as it is the report of a case of a very rare cardiac abnormality. Of the papers on tuberculosis, that dealing with gold therapy is likely to be useful as it is based on observations on a number of hospital cases. In the section of surgery, most of the papers are on special branches of surgery, the only paper on general surgery being that on strangulated hernia.

The papers on epidemic dropsy glaucoma deal with the different methods of treatment of this serious complication of epidemic dropsy. In the section of midwifery, the articles on ectopic gestation, blood pressure in pregnancy, paracentesis in the treatment of hydramnios, will be read with interest. The article on terata anadidyma gives record of a pathological curiosity and details of management of labour complicated by double monsters.

The students' section records the history of the Medical College Students' Club and the activities of the athletic, dramatic, social service and scientific sections of the students' club.

The format, printing, and illustrations are very satisfactory. The scientific sub-committee of the reunion who are responsible for this publication deserve congratulation.

Abstracts from Reports

EIGHTH ANNUAL REPORT OF THE KING GEORGE THANKSGIVING (ANTI-TUBERCULOSIS) FUND FOR THE YEAR 1938

THE most important feature of the year so far as tuberculosis in India is concerned was the successful result of Her Excellency the Marchioness of Linlithgow's appeal. The collection of funds has been associated with such a wide educational campaign that 1938 will be remembered as a special anti-tuberculosis year.

The appeal has met with a generous response but its success cannot only be judged by the amount of collections, for widespread attention has been focused on the dangers and problems of this disease. The good that has been achieved in this direction can never be measured; it may not be apparent to-day, but it is very real, and if the effort is sustained, we can count on the continued support of well-planned measures that will be initiated under the new scheme.

It is, however, advisable to remind the public that tuberculosis cannot be controlled by the building of tuberculosis institutions or by the application of any one method, and that the improvement of the health conditions, in particular housing, nutrition and the care of the health of the children are not only sound and successful anti-tuberculosis measures but are essential complements of a complete anti-tuberculosis scheme.

At the request of Her Excellency the Marchioness of Linlithgow, the King George Thanksgiving (Anti-Tuberculosis) Fund appointed two sub-committees, (1) a technical committee of medical men with expert knowledge of tuberculosis problem in India and (2) a constitution-drafting committee to consider the policies and planning of the proposed All-India Tuberculosis Organization to be formed as a result of the King-Emperor's appeal.

The recommendations of the technical committee on being accepted by the fund committee were submitted to Her Excellency and issued from the appeal office as a note on the tuberculosis problem in India for the guidance of provincial organizations.

TRAINING OF TUBERCULOSIS WORKERS

(a) Post-graduate courses

Training of doctors in the modern methods of diagnosis, prevention and treatment of tuberculosis is an established activity under the fund. Post-graduate courses have been held since 1935 and 220 doctors have

so far received training, but the demand for training from provinces and states is still increasing. Forty-five doctors were selected out of 300 applicants for training, during the year, at two courses held at the All-India Institute of Hygiene and Public Health, Calcutta (January-February 1938) and Mayo Hospital, Lahore (November-December 1938). The selection was as far as possible equitably distributed over the different provinces and states and due regard was paid to the candidates' past experience in tuberculosis. As in previous years no admission or tuition fees were charged and we paid the out-station candidates single second-class fare up to a maximum of Rs. 100.

(b) Training of tuberculosis health visitors

In our last annual report we referred to the increasing demands for trained tuberculosis health visitors in connection with the work of the tuberculosis clinics, that had been or were to be opened. A tentative scheme for special training of fully qualified nurses for this work was drawn up in 1936, but from the information collected through the heads of the provincial medical departments, regarding the condition of nursing services and the best type of worker to meet the peculiar conditions in India, it became clear that though in theory a fully-qualified nurse with special training in tuberculosis is essential for this work, in practice, trained nurses are not available. In some of the provinces a nursing profession hardly exists and such nurses as there are find employment in general hospitals, which are all understaffed. Moreover in isolated instances where such candidates are available, the provincial organizations are unable to find the high salaries demanded by such workers. It was suggested that matriculate girls with a special course of training (6 to 9 months) in tuberculosis and in general health visiting work should meet the conditions peculiar to India.

The fund committee at their meeting of the 17th February appointed a technical committee to re-consider the scheme in the light of information available from the provinces.

The scheme suggested by the sub-committee was approved by the fund committee with minor alterations and Rs. 3,500 sanctioned for the first course in 1939. The main points about the scheme are:—

1. That the fund committee should undertake the training of tuberculosis health visitors at Delhi with

the help of the Lady Reading Health School and the Silver Jubilee Tuberculosis Hospital.

2. That the first course be open to women only.

3. That only candidates recommended by the provincial and state sub-committees be accepted for training. Private candidates will be accepted only for special reasons and on special terms.

4. That the maximum number of students should not exceed 10 in each course.

5. That candidates need not be qualified nurses for health visitors, but must be at least matriculates of a university or possess some equivalent qualification.

6. That the candidates must not be under 21 years of age.

7. That the period of training should be six months followed by a probationary period of one month at a tuberculosis clinic under the provincial committee recommending the candidate or in Delhi. The period of training to be divided as under:—

(a) Three months at the tuberculosis hospital mainly devoted to practical nursing of the tuberculosis patient and to include a theoretical course of at least ten lectures on tuberculosis followed by

(b) Three months' course at the Lady Reading Health School for theoretical lectures and practical home visiting. Syllabus to cover the following:—

(1) Hygiene—

Personal hygiene	} 25 lectures.
General	
Public health administration.	
school hygiene, industrial hygiene.	

(2) Domestic science—

Household management	} 25 lectures.
Cookery	
Dietetics	
Elementary economics	

(c) Qualified health visitors should be exempted from the three months' course at the Lady Reading Health School.

(8) A certificate should be granted by the fund committee to the successful candidates on the termination of the course.

(9) The first course should be started in January 1939.

(10) Each candidate should receive a stipend of Rs. 20 per month, with free furnished quarters which will be provided by the tuberculosis fund.

(11) The employment and pay of successful candidates will be a matter entirely for the provincial tuberculosis committees who depute them for training. Seventeen applications were received through the provincial state committees and ten candidates have been selected with due regard to the territorial distribution and the development of the tuberculosis clinics in each area. The course was inaugurated on the 16th January and is now in progress.

Educational activities

The educational activities from the centre have been directed mainly towards creating contacts with and stimulating interest of individuals and organizations interested in public welfare. It was emphasized during this year that the best way of attracting public opinion is through the educated section of the community and that short special courses are a very useful form of activity. Short courses on tuberculosis among organized groups like teachers, university students, St. John Ambulance Brigade Overseas Divisions, and nurses have been organized with the help of the authorities concerned and all necessary help was given from headquarters.

(a) *Popular literature*

The fund maintains a stock of suitable educative material in various languages. Ten thousand two hundred and twenty-six pamphlets and leaflets and 8,678 posters and charts were distributed free through educational institutions, public libraries, maternity and child welfare centres, health exhibitions and other

social organizations. Sales of stocks registered a marked increase, 11,273 pamphlets and 53,506 posters and charts being sold as compared with 4,166 pamphlets and 14,014 posters and charts in 1937.

The following new literature was issued during the year:—

1. What a teacher should know about tuberculosis; in English, Urdu and Hindi.

2. Prevention of tuberculosis; in Hindi.

3. A dangerous teacher and the lessons he teaches about tuberculosis; in English. (By Dr. C. Fridmott-Möller.)

4. Anti-tuberculosis work in Bengal; in English. (By Dr. A. C. Ukil.)

(b) *Tuberculosis slides*

A new set of 21 slides was prepared during the year. This set proved popular. Twenty-one sets were issued from the dépôt as compared with 11 in 1937.

(c) *Tuberculosis films*

Our tuberculosis films were in great demand this year and were circulated through the Red Cross film circulating library. Three copies of the films causation and prevention of tuberculosis were sold during the year.

(d) *Red Cross Journal*

News about tuberculosis activity and popular articles on tuberculosis have been contributed to the journal throughout the year.

Co-ordination of provincial activities

To meet the difficulty of early diagnosis of open cases amongst poor patients the fund committee approached the local governments through its provincial/state committees, to provide free sputum-examination facilities for poor patients on the recommendation of a qualified medical practitioner, at all public health laboratories and district and taluq hospitals. The Government of India was also requested to commend this proposal to all Provincial Governments.

Information bureau

The fund office is the Central Information Bureau regarding all matters relating to tuberculosis in India. Large number of enquiries from organizations and individuals are answered and this work has considerably increased during the last two years.

Hasan-Masud Suhrawardy Memorial Anti-Tuberculosis Challenge Shield

The shield was awarded to Delhi Municipality for having shown the best anti-tuberculosis activity in 1937. It is a work which attracted attention not only by its sound organization on general principles but by its rapid growth during its short period since 1936.

The anti-tuberculosis activities are many-sided and are well co-ordinated through the Public Health Department, which is in charge of the educative part of the work.

The housing schemes in Delhi under the Municipality and the Improvement Trust whereby some slums have been cleared, insanitary *bustees* removed and arrangements made for housing poor people in new areas are such that they are bound to have a permanent effect on the anti-tuberculosis movement in this city.

(a) *International Union Against Tuberculosis*

Close co-operation has been maintained with the Union. The fund continued to be a member with General Bradfield and Dr. Ukil as councillor members. All enquiries made by the Union have been answered and specimen posters and literature issued by the fund have been sent to anti-tuberculosis organizations who are members of the Union. We kept in touch with the anti-tuberculosis work in other countries through the *Quarterly Bulletin* of the Union. Copies of this bulletin were supplied to all provincial/state committees.

Research

Research in tuberculosis is an activity under the Indian Research Fund Association.

Dr. C. Frimodt-Møller attended the 16th Research Workers' Conference at New Delhi from 12th December to 17th December, as a representative of the King George Thanksgiving Fund and Mr. B. K. Sikand, Organizing Secretary, worked as the Joint Secretary of the Tuberculosis Advisory Committee of the Conference.

The main lines of work under Dr. Ukil with regard to tuberculosis in relation to the jute industry and its 'dust hazards' was continued. Further investigation has confirmed previous years' findings.

In 1938, the work was extended to a tuberculosis survey amongst students and nurses of the K. E. Medical College, Lahore, and school children at Amritsar.

Headquarters library

Books to the value of Rs. 105 were added during the year to the tuberculosis reference library at headquarters. Several workers took advantage of this library.

INDIAN RED CROSS SOCIETY, NEW DELHI: ANNUAL REPORT FOR THE YEAR 1938

REPORT OF THE MANAGING BODY

THE Indian Red Cross Society continued its general peace-time activities and in addition provided assistance for relief work to sufferers from the floods in Bengal and Assam, and for famine in the Hissar District in the Punjab.

In response to an appeal of the International Red Cross for the continuation of relief operations in Spain the Indian Red Cross Society made a monthly contribution of Rs. 250 during the last six months of the year under review and two provincial branches made similar monthly contributions through the Society, making a total of Rs. 2,285 during the year.

The International Red Cross made further appeals for relief work in China and early in the year the Society made a contribution of Rs. 5,000. A contribution of Rs. 3,662 was also made by branches for the same cause. Towards the end of the year, on receipt of further news of serious distress in China the Society voted a sum of Rs. 1,500 and arranged to send a supply of drugs. It also issued an appeal for funds and gifts of drugs and provisions through the press.

The Indian Red Cross Society delegation to the XVIth International Red Cross Conference held in London was led by Major-General E. W. C. Bradfield in the absence of Sir Firoz Khan Noon, who was at the time in Geneva.

The Society made its usual subscription of Rs. 1,000 to the International Red Cross Committee, Geneva, and increased its annual contribution towards the administrative expenses of the League of Red Cross Societies, Paris, to £250 sterling. The Society has further agreed to increase the contribution to an equivalent to 1,250 dollars = £258 at the request of the League for the year 1939.

The separation of Burma from the administrative control of India and the subsequent formation of a new Red Cross Society in Burma which had been a branch of the Indian Society entailed an adjustment of funds which with the necessary legal formalities was completed during the year. A sum of Rs. 5,24,800 was transferred to Burma.

The total number of branches of the Red Cross in India at the end of 1938 was 26 provincial and state and 265 district branches compared with 25 and 241 respectively last year. Khairpur and Indore States formed separate branches in direct affiliation with headquarters.

The Annual General Meeting of the Society took place as usual at the Viceroy's House on 24th March and was well attended. His Excellency the Marquess of Linlithgow presided and their Excellencies graciously invited members and guests to an at home before

the meeting. Earlier in the day an informal conference of delegates took place at the Red Cross Building when the relation of the Red Cross with the St. John Ambulance Association and Brigade Overseas and the Red Cross plan of collections for the King-Emperor's Anti-Tuberculosis Fund were discussed. The new Red Cross film on 'Self-help in Villages' was exhibited.

One of the primary duties of the Indian Red Cross Society is to provide for medicine and other aid to the sick and wounded in the event of war and the mobilization plan is a comprehensive scheme which embraces the activities of the Indian Red Cross Society, the St. John Ambulance and St. John Ambulance Brigade Overseas as an auxiliary to the army medical and nursing services in time of war. This important plan has been drawn up in consultation with provincial organizations and will ensure the fullest possible co-ordination between headquarters and branches when put into action. The Red Cross Roll of Trained Nurses for War and Disaster which forms part of the mobilization plan had 68 nurses on the list.

Headquarters and branches continued to take a very active interest in the appeal made by Her Excellency the Marchioness of Linlithgow for the King-Emperor's Anti-Tuberculosis Fund. In addition to providing office accommodation to the appeal fund staff headquarters distributed propaganda folders in English, Urdu and Hindi, supplied special lantern slides, movie film leaderettes and propaganda dialogue on the subject for broadcasting from all radio stations in India in their rural hour programme. The branches also took an active part in the campaign for the collection of funds in their own areas throughout the year. In November His Excellency the Viceroy was pleased to approve the scheme of the dissociation of the King George Thanksgiving (Anti-Tuberculosis) Fund from the Indian Red Cross Society with a view to the formation of an independent Tuberculosis Association of India.

KING GEORGE THANKSGIVING (ANTI-TUBERCULOSIS) FUND

The Fund has since November 1930 continued to be administered by a sub-committee of the Society. During 1938 Major-General Bradfield was the Chairman of the sub-committee and Dr. B. K. Sikand its Organizing Secretary.

The outstanding feature of the year was the successful appeal of Her Excellency the Marchioness of Linlithgow for the King-Emperor's Anti-Tuberculosis Fund. Her Excellency in issuing the appeal stated that if it was successful the intention was to found a Tuberculosis Association for India, consisting of a central body supported by affiliated provincial and state organizations. The setting up of a comprehensive organization with the help of the new fund will mark a new and important development towards a more effective control of tuberculosis in India.

MATERNITY AND CHILD WELFARE BUREAU

The committee of the Maternity and Child Welfare Bureau administered the funds of the Lady Chelmsford League, the Victoria Memorial Scholarships Fund and the Army Child Welfare Fund.

The funds of the Lady Chelmsford League were distributed mainly as grants-in-aid of training schools. The schools for health visitors in Delhi, Calcutta, Madras, Rangoon and the new school in Poona received grants during the year.

The Madras Health School was closed in March 1938 and the funds thus made available were diverted towards the support of the newly opened training school for Nursery School Teachers, Madras. The Nursery School and Kindergarten, Mysore, and the School of Mothercraft, Bareilly, also received grants.

A scholarship was provided for a medical woman graduate for the course of the Diploma in Maternity and Child Welfare at the All-India Institute of Hygiene and Public Health, Calcutta. A few additional grants were given direct from Bureau funds to certain maternity and child welfare schemes, one of

which was a grant towards the work of the Najafgarh Rural Unit.

The majority of civil welfare centres aided by Indian Red Cross funds received their grants direct from the provincial branches of the Indian Red Cross Society.

The Victoria Memorial Scholarships Fund was distributed almost wholly as grants-in-aid for *dai* training. Grants were given to seven *dai* training schools. Other aided schemes give institutional and domiciliary training, or are entirely domiciliary, the training being carried on in connection with welfare centres. Some of the *daies* on completion of training and after passing an examination receive V.M.S. certificates of which 139 were issued during the year, while others are given the trained-*dai* certificates of the province or state *dai* school.

The Army Child Welfare Fund was distributed to 54 Indian and 26 British Army centres during the year 1938. Army child welfare work owes much to the help and enthusiasm of voluntary workers and the progress in this field is marked. But the lack of training in preventive work of sub-assistant surgeons and nurses appointed to Army child welfare centres, is in many cases a handicap to constructive work, and facilities for such training for sub-assistant surgeons and the replacing of nurses and midwives by trained health visitors is much to be desired.

The Junior Red Cross activities for the promotion of health increased in all directions, specially in anti-epidemic and village improvement work.

At the request of the High Commissioner for India a comprehensive series of exhibits were supplied to the Women's Pavilion at the Glasgow Empire Exhibition; these included posters, pamphlets and cut-out models showing the part taken for relief of disaster and work among women and children.

The Depot distributed a large amount of health and Red Cross propaganda material to provincial, state and district branches, and also to Government departments of health, private bodies, health centres, educational institutions, officials and others.

There were two railway accidents, one in U. P. on the G. I. P. Railway near Bamrauli and the other in Madras on the South Indian Railway near Madura for which the services of nurses on the Red Cross Roll of Trained Nurses for Disasters were offered, but the services were not needed. A grant of Rs. 1,000 was given each to Assam and Bengal for relief work to the sufferers of floods in the provinces. For famine relief measures in Hissar District in the Punjab a sum of Rs. 500 was granted.

Indian ex-service men were assisted as before through the Soldiers Boards. The U. P. Branch paid for the treatment of 17 ex-soldiers suffering from tuberculosis at the Bhowali Sanatorium and the Punjab Branch for giving institutional treatment to 14 ex-soldiers.

ANNUAL REPORT OF THE PUBLIC HEALTH DEPARTMENT IN THE CENTRAL PROVINCES AND BERAR FOR THE YEAR 1937

THE year 1937 was comparatively a healthy one. The death rate was 32.63 per thousand of the population as against 34.89 in the preceding year and the quinquennial average 31.98. This is satisfactory as far as it goes, but much leeway has yet to be made up as the mortality rate of the province is still the highest in India. The Provincial Government are convinced of the necessity of a fully-trained and whole-time public health service on which will fall the responsibilities of studying the epidemiological conditions and organizing and supervising such important matters as water-supply, vital statistics, infant and maternal welfare, hygiene and nutrition. As a step in the direction of the expansion of the public health department, Government have made provision in the current year's budget for the appointment of twenty-five sub-assistant health officers, in addition to the present staff. This will give one sub-assistant health officer to each *tahsil* in the province.

Although the mortality from malaria during the year fell from 274,670 to 267,558, the disease continued to take a heavy toll, being responsible for 53 per cent of the total mortality from all causes. The evil is so widespread that many people regard it as inevitable and its eradication as impracticable. In reality, however, malaria is neither inevitable nor incurable. Drainage and flushing, oiling of stagnant water and mosquito curtains will prevent it, while quinine will cure it. Prevention is clearly the right policy, but it will take time to bring the disease under control in this province. Meanwhile, Government desire to see no efforts spared to make quinine more easily available and at cheaper rates in all parts of the province.

There is a fall in the mortality from all causes except plague and dysentery. The ravages of plague in recent years have not been so great as in the past, but the public should not be lulled into a false sense of security. If the scourge is to be driven out of the province all local bodies must intensify anti-rat campaigns. The main causes of the major infectious bowel disease of the province, *viz.* cholera, typhoid fever and dysentery, are known to be avoidable and can be traced to bad water-supply, primitive conservancy arrangements and unsatisfactory drainage.

The mortality among infants under one year of age fell from 234.98 per thousand births to 218.16, the quinquennial average being 222.63. The rate is, however, still the highest in India, the lowest being 115.86 in the neighbouring province of Bihar. The main causes of the infantile mortality are prematurity, inanition, malnutrition (chiefly owing to want of mother's milk), diarrhoea, respiratory diseases and fevers. The child welfare and maternity movement, which is making steady progress, is intended to take effective measures to minimize their evil.

Government are greatly concerned about the prevalence of leprosy in the province and are considering the extension of anti-leprosy measures. Four new clinics were opened during the year—two by Government and two by the British Empire Leprosy Relief Association. Provision has also been made in the current year's budget for the establishment of three more leprosy centres. This will bring the total in the province to 40. With a view to organizing public opinion on the subject and carrying on educative propaganda, Government have decided to introduce a scheme for the establishment of district leprosy councils and propose in the current year to open five such councils in the districts where the disease is most widely prevalent.

Correspondence

A NOTE ON SOME CASES OF LATHYRISM IN A PUNJAB VILLAGE

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—I have read with much interest Dr. Shah's article on lathyrism cases in a Punjab village and your leader commenting on this article in the July number of the *Indian Medical Gazette*.

This once more raises the controversy, toxin *versus* avitaminosis, and it is naturally of great interest to me to see that so far as this outbreak goes it appears to support the *akta* theory as originally conceived by Mr. A. Howard (now Sir Albert Howard), at that time Imperial Economic Botanist to the Government of India, and subsequently worked on by Dr. J. L. Simonsen and myself in association with him.

The absence from cultivation or consumption as a foodstuff in the area concerned of *L. sativus* would appear to have definitely exploded the theory that this pulse has a direct causal relationship to the disease, a conclusion which we reached, of course, in 1925, but though the contamination of the wheat with

V. saliva provides a tempting and suggestive alternative. this fact, as you point out, unfortunately does not exclude other possible causes such as avitaminosis.

Whilst this question, therefore, still requires an answer I can say with assurance that the disease we produced in animals as a result of feeding them with *akta*—if indeed it corresponds to lathyrism in the human subject—was not due to any lack of antineuritic vitamin in the *akta* seeds.

Owing to the superficial resemblance to polyneuritis columbarum of the disease exhibited by ducks poisoned

by *akta*, we conducted a number of experiments (unpublished hitherto) on pigeons, to determine whether or no *V. saliva* was deficient in antineuritic vitamin.

The Antineuritic Value of *Akta* (*Vicia sativa* var. *Angustifolia*).

Pigeons were fed on an exclusive diet of autoclaved rice, as described by McCarrison, until polyneuritis was fully developed and the birds were at the point of death. At this point a very small quantity of rice was replaced by raw *akta* seeds. The introduction of even as little as 3 g. daily of these seeds rapidly brought about a cure of the polyneuritic symptoms and complete recovery of the birds in four to five weeks. Control birds invariably died after three to four weeks on the exclusive diet of autoclaved rice unless supplemented by the fresh seeds.

Three grams of *akta* seeds, of course, represented only a few seeds scattered among the mass of 50 g. of rice, and it was interesting to see how the sick birds

immediately picked out the raw seeds and how rapidly appetite and consequently the food intake was increased and accompanied by an increase in body weight. None of the birds in this little experiment suffered from the disease we had associated with *akta* poisoning (? lathyrism), either because the quantity of *akta* ingested was too small, or the duration of the experiment was too short. But, of course, the object of the experiment was only to show that the seeds were not deficient in antineuritic vitamin.

The accompanying graphs show the result of this experiment with three pigeons and corresponding controls.

The graphs show that the vitamin content of 3 g. of *akta* (pigeon no. 4) is ample to bring about a cure of polyneuritis in pigeons, whilst 1 g. of the seeds (pigeon no. 3) though sufficient to prolong life and bring about an improvement in the condition of the birds, is probably insufficient to establish a complete cure.

Yours, etc.,

L. A. P. ANDERSON,
LIEUTENANT-COLONEL, I.M.S.

DEMANDS OF MEDICAL FEES FROM MEDICAL MEN

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—I would very much like your opinion on the subject of fees payable by medical men to other medical men for professional attendance on themselves or their families?

Of specialists who expect, or even demand, a fee one hears much more frequently now than, say, twenty years ago.

Personally, I do not accept a fee. When medical men consult me regarding themselves or other medical men or their families (including widows) and want to know about payment I tell them that the question of payment does not arise. Am I wrong?

I have had occasions to consult medical men in Europe. They have not charged me. From recent accounts given by colleagues, regarding attendance on their families, the position in England, however, does not appear to be clearly defined.

Yours, etc.,

MEDICAL USAGE.

CALCUTTA,
31st August, 1939.

SNAKE BITES AND THEIR TREATMENT IN INDIA

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—In the July issue of the *Indian Medical Gazette* a very interesting article 'Snake Bite' by Colonel Chopra and Captain Chowhan was published.

It is mentioned in the article that 'viper' bite prevents clotting of blood, thus encouraging oozing of blood from the nose, vagina and stools, etc.

It is not clear to me why this same viper venom is successfully employed in cases of haemophilia or bleeders, and allied diseases where the coagulability of blood is delayed or prevented.

In other words, this viper venom is used as a cure for the same disease that it produces. I have in various medical discussions on this side endeavoured to find out a suitable reply to this query, but it has been always asserted that there are two varieties of vipers and the viper whose venom is employed as a cure for bleeders is quite different from the other variety of vipers.

I have to request you to clear this point.

Yours, etc.,

S. A. SUBEDAR, L.C.P.S., R.M.P.

KUTIYANA,
W. KATHIAWAR,
4th August, 1939.

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—With reference to Dr. Subedar's enquiry regarding the anomalous action of viper venom, there had been already a good deal of discussion on its different actions, pharmacologically and therapeutically. In mammalian and human blood both these actions depend on the dose of the venom injected and its concentrations in the blood. To be clearer these different actions may be explained as follows:—

(a) *Viper venom as a coagulant agent.*—Macfarlane and Barnett (1931, *Lancet*, ii, 985) have shown that in as low concentration as from 1-10,000 to 1-10⁶, Russell's viper venom, when brought in contact with blood *in vitro*, causes immediate coagulation. For this property this venom has been used therapeutically to stop hemorrhages and other conditions of bleeding diatheses.

(b) *Viper venom as a hemorrhagic agent.*—Russell's viper venom produces severe hemorrhages in all the serous cavities, lungs, brain, kidneys, skin, etc., when injected pharmacologically in big doses in experimental animals or when a victim is bitten fatally. We have shown that this venom has a strong proteolytic property; it digests fibrin and jellies rapidly.

The above antagonistic actions of Russell's viper venom may be explained thus: When the venom enters the general circulation its concentration is low, and hence it causes at first coagulation of blood fibrin, and such fibrin clots are observed at post-mortem

examinations in big vessels and in the chambers of the heart, but later as the concentration rises the clot is digested again by the excess amount of venom in the blood. The blood becomes fluid and fibrin free, as if it had been defibrinated. This action has been explained in other ways as well, i.e., the dose of venom injected at each bite is so big that the blood has no time to clot since the whole of the fibrin is digested by the venom; also there is a severe damage to the endothelial lining of the capillaries with consequent extensive hemorrhages.

Service Notes

APPOINTMENTS AND TRANSFERS

THE VICEROY AND GOVERNOR-GENERAL has been pleased to make the following appointment on His Excellency's Personal Staff:—

To be Honorary Surgeon

Colonel D. H. Rai, M.C., vice Colonel A. F. Babonau, C.I.E., O.B.E., vacated. Dated 22nd June, 1939.

Colonel D. H. Rai, M.C., returned from leave and resumed charge of the Office of Inspector-General of Civil Hospitals, C. P. and Berar, from 26th August, 1939.

Lieutenant-Colonel J. M. Mitchell, O.B.E., to be Officiating A. D. M. S., Kohat District. Dated 31st July, 1939.

Lieutenant-Colonel M. S. Joshi to be Officiating A. D. M. S., Peshawar District. Dated 3rd July, 1939.

Lieutenant-Colonel P. R. Vakil to be O. C., I. M. H. Nowshera. Dated 2nd July, 1939.

Lieutenant-Colonel A. N. Sharma to be Officiating O. C., I. M. H., Delhi. Dated 30th June, 1939.

Lieutenant-Colonel J. C. Chukerbuti to be O. C., I. M. H., Jubbulpore. Dated 15th July, 1939.

Lieutenant-Colonel R. S. Aspinall, C.I.E., Agency Surgeon, on return from leave, resumed charge of his appointment as Chief Medical Officer in the Western India States Agency and Residency Surgeon, Rajkot, with effect from the afternoon of the 5th August, 1939.

Lieutenant-Colonel A. J. D'Souza, on return from leave, assumed charge of the duties of the Civil Surgeon, Moulmein, on the forenoon of the 4th August, 1939.

Lieutenant-Colonel N. S. Jatar, C.I.E., D.S.O., Inspector-General of Prisons, C. P. and Berar, ceased to hold the additional charge of the Office of Inspector-General of Civil Hospitals, with effect from the 26th August, 1939.

Lieutenant-Colonel B. H. Singh, M.C., Civil Surgeon, Mysnensingh, is appointed as Civil Surgeon, Howrah, vice Captain J. White, transferred.

Major A. N. Chopra was transferred to Civil employment in C. P. and Berar. Dated 11th July, 1939.

Major D. P. Lambert, Civil Surgeon, Meerut, reverted to Military from 3rd August, 1939.

Major M. R. Sinclair posted as Civil Surgeon, Agra, from 3rd August, 1939.

Major C. A. Bozman is appointed to the Civil Branch of the I. M. S., with effect from the 1st April, 1937. He will count his seniority in civil employment from the 9th August, 1933.

(Previous notification, in so far as it relates to Major Bozman, is cancelled.)

Captain M. G. Saincher reverted to military duty at the I. M. H., Secunderabad, from the Hyderabad State Service on 18th July, 1939.

Captain I. J. Franken-Evans was transferred to Civil employment at the Irwin Hospital, Delhi. Dated 19th July, 1939.

Captain W. A. N. Marrow to be Officiating O. C., I. M. H., Poona. Dated 26th July, 1939.

Captain W. S. Empey, O.B.E., left the I. M. H., Ambala, for duty with the Army in Burma on 30th July, 1939.

Captain Shwe Zan, on transfer from the Military Department, assumed charge of general duty at the Rangoon General Hospital, on the afternoon of the 4th August, 1939.

Captain S. Ahmad transferred from Agra to Fyzabad where he assumed charge on 8th August, 1939.

Captain J. W. D. Goodall, Civil Surgeon, Midnapore, is appointed as Second Resident Medical Officer, Presidency General Hospital, Calcutta, vice Dr. W. A. Browne, transferred.

Captain J. White, Civil Surgeon, Howrah, is appointed as Civil Surgeon, Midnapore, vice Captain J. W. D. Goodall, transferred.

Captain R. L. Raymond, on return from leave, assumed charge of the duties of Ophthalmic Surgeon, Rangoon General Hospital, on the forenoon of the 24th August, 1939.

Lieutenant G. T. Hayes is restored to the establishment. Dated 1st May, 1939, with seniority from 1st May, 1938.

To be Lieutenant (on probation)

Vivian D'Arcy Blackburn. Dated 11th April, 1939, with seniority from 11th April, 1934.

Indian Land Forces

(Short Service Commission)

To be Lieutenants

Dated 22nd June, 1939

Balbir Krishna Kapur.
Prem Chandra Dhandu.
Panavelil Thomas Joseph.
Hans Raj Pasricha.
Nityananda Chakravarti.
Mohammad Sarwar.
Dhruva Kumar Bose.
Sailendra Nath Chatterjee.
Komattil Kumara Menon.

Dated 24th June, 1939

Mohammad Seraj-ul-Haque.

LEAVE

Colonel D. C. V. Fitzgerald, M.C., K.H.P., A. D. M. S., Madras District, proceeded on 3 months and 5 days' combined leave in and *ex-India*, pending retirement, with effect from the 17th July, 1939.

Brevet-Colonel J. W. Vanreenan, O.B.E., O. C., I. M. H., Abbottabad, proceeded on 3 months and 5 days' combined leave *ex-India* from 7th July, 1939.

Lieutenant-Colonel J. L. D. Yule, O. C., I. M. H., Delhi, proceeded on 12 months' combined leave *ex-India* from 30th June, 1939.

Lieutenant-Colonel H. E. Murray, Officiating Professor of Midwifery, Medical College, Calcutta, is granted leave for 6 months, with effect from the 21st August, 1939, or from the date of relief.

Major B. Chaudhuri, Senior Medical Officer, Port Blair, is granted an extension of leave on average pay from the 1st August to 28th September, 1939, and his services are placed at the disposal of the Government of Bengal, with effect from the 29th September, 1939.

Captain F. W. Allinson, First Resident Medical Officer, Presidency General Hospital, was granted leave for 12 months, with effect from the 3rd March, 1939. Previous notification is hereby cancelled.

Captain A. E. Kingston was granted leave for 1 year, including 8 months on average pay and 4 months on half-average pay, from the forenoon of the 1st August, 1939.

Captain C. C. Kapila was granted leave for 1 year, including 8 months average pay and 4 months on study leave from the 15th August, 1939.

Captain R. D. MacRae, an Officiating Agency Surgeon, is granted leave on average pay for 4 months combined with study leave for 3 months and leave on half-average pay for 5 months, with effect from the afternoon of the 15th October, 1938. Previous notification is hereby cancelled.

PROMOTIONS

Lieutenant-Colonels to be Colonels

R. Sweet, D.S.O. Dated 21st June, 1939, with seniority from 25th July, 1935.

A. C. Macrae. Dated 21st June, 1939, with seniority from 25th July, 1935.

To be Brevet-Colonel

Lieutenant-Colonel A. MacD. Dick, C.B.E., V.H.S. Dated 1st July, 1939.

Major to be Lieutenant-Colonel

M. P. Atkinson. Dated 12th August, 1939.

Captains to be Majors

P. V. Bamford. Dated 15th July, 1939.

H. D. R. Zscherpal, M.B.E. Dated 15th July, 1939.

K. Jilani. Dated 26th July, 1939.

D. H. Waldron. Dated 26th July, 1939.

C. H. Dhala. Dated 8th August, 1939.

J. R. Dogra. Dated 25th August, 1939.

S. Narain. Dated 25th August, 1939.

Captain to be Major (provisional)

S. Kharegat. Dated 15th July, 1939.

Lieutenants (on probation) to be Captains (on probation)

C. C. Harvey. Dated 24th May, 1939, with seniority from 1st July, 1938.

D. F. Eastcott. Dated 1st July, 1939.

L. H. Cooper. Dated 1st August, 1939.

To be Captain (on probation)

Henry Bunting Wright. Dated 7th June, 1939, with seniority as Lieutenant from 21st June, 1933, and as Captain from 21st June, 1934.

RELINQUISHMENTS

The undermentioned Officers relinquished their probationary appointments:—

Captain J. H. Briscoe-Smith. Dated 5th July, 1939.

Lieutenant O. T. Mansfield. Dated 3rd July, 1939.

RETIREMENTS

Colonel W. L. Watson, O.B.E. Dated 21st June, 1939.

Colonel N. S. Sodhi, M.C. Dated 9th August, 1939.

Brevet-Colonel R. N. Chopra, C.I.E., K.H.P. Dated 17th August, 1939.

Lieutenant-Colonel A. W. Duncan. Dated 11th July, 1939.

The following retirements, with gratuity, are permitted subject to His Majesty's approval:—

(Short Service Commission)

Captain M. L. Gujral. Dated 19th May, 1939.

Captain Mohan Singh. Dated 21st May, 1939.

Captain D. R. Sharma. Dated 23rd May, 1939.

Captain P. S. Bassalvi. Dated 23rd May, 1939.

Captain G. N. Ahmadi. Dated 25th May, 1939.

Captain B. S. Bindra. Dated 16th June, 1939.

Captain W. A. Mirza. Dated 21st June, 1939.

RESIGNATIONS

Captain A. H. W. Mitchell. Dated 18th April, 1939.

Captain G. C. A. Jackson (ill health). Dated 14th July, 1939.

Captain N. P. Woodgate-Jones. Dated 10th July, 1939.

Captain J. W. Richmond. Dated 26th July, 1939.

Notes

FUNCTIONAL UTERINE HÆMORRHAGE
TREATED BY TESTOSTERONE PROPIONATE

Mrs. M., aged 25, one child aged 6. History of repeated irregular and severe uterine hæmorrhage, and she had been curetted two or three times for this.

In January 1938 she had curettage for pain and severe hæmorrhage and a portion of the retained placenta was removed. After this she appeared to improve for some time and the periods became regular, lasting seven or eight days, while the pain disappeared.

Then in June 1938 she started with pain in the right side and hæmorrhage. The hæmorrhage occurred every two or three days, lasting three or four days at a time, and the loss was considerable. She also states that while she was pregnant with her child six years ago she had her periods the whole nine months. There is nothing else in the history of note.

Examination revealed a thinnish, extremely pallid woman. There was nothing abnormal in her heart, lungs, liver, spleen or kidneys. The teeth and throat were clean, pupils and reflexes were normal. There was slight psoriasisiform eruption over the left hip. Wassermann was negative.

The patient was admitted to hospital on 31st October, and under gas and oxygen anaesthesia vaginal examination disclosed the following: A smallish retroverted mobile uterus, and the right ovary was slightly enlarged and felt cystic and the rest of the adnexæ appeared normal. Dilatation and curettage were performed and the uterine scrapings were sent to the South African Institute for Medical Research for biopsy. The following is the report: 'There is no evidence of lesion of the metropathia hæmorrhagica and endometrium is in the lutein phase. There is some slight interstitial endometritis'.

On the 12th November, 1938, treatment was commenced with Testosterone propionate (Testoviron-Schering) 20 mgm. intramuscularly twice a week. On the 21st November there was a very slight sore and pain in the right side was much better. On the 24th November she reported there was no hæmorrhage since 17th November. On the 26th November there was a slight sore and on the 6th December she reported that she had hæmorrhage from the 4th to 6th December.

During this time treatment was stopped as this was probably a true period. On the 9th December

treatment was resumed and on the 30th December treatment was stopped. On 7th January, 1939, a period started lasting five days and was strong for the first two days. No more treatment was given, and on the 3rd February periods started again and finished on the 7th. The flow was not unduly severe. On 20th February dilatation and curettage were done again and scrapings sent to the South African Institute for Medical Research, and the report is as follows: 'No evidence of luteinization and the endometrium shows characters of the quiescent resting stage'.

Here we have a case of obvious over secretion—of Progesterone caused by the probable presence of small lutein cyst in the right ovary. In view of this, treatment with Progesterone was contra-indicated and therapy with follicular hormone and gonado-tropic appeared to have no physiological indication. Therefore a trial was made with the male hormone. Zuckerman has done considerable work with the male hormone (Testosterone propionate) in female *rhesus* monkeys and in the baboon. He found that the male hormone had an inhibiting effect on the folliculization and luteinization and was able to produce amenorrhœa with it. Other workers have had similar results in human females, hence I was prompted to try it, rather than to resort to operative interference, with the above successful results.

One had anticipated producing amenorrhœa of a temporary character but this never occurred. The patient received in all 240 mgm. of the male hormone and there was no unpleasant sequelæ such as hirsuties, enlargement of the clitoris, etc., in fact, she has received nothing but benefit.

She has had no treatment since 30th December, 1938, since when she has had two comparatively normal periods with no intervening hæmorrhage. This patient is apparently quite cured; her general health is much improved and her pallor has disappeared.

B. W. FRANKLIN BISHOP, M.B.,

Kimberley.

(From the *South African Medical Journal*,
25th March, 1939, p. 211.)

A METAL BOUGIE-CATHETER

THE Mayo Hospital, Nagpur, is a hospital at which assistant medical officers are trained. These students both post-graduates and under-graduates have to be taught how to relieve retention of urine in the male without causing unnecessary damage to the urethra. Many of the cases of retention of urine, which come to the hospital, are of a difficult and serious nature owing to the prevailing neglect of proper treatment of gonorrhœa. I have found Phillips filiform bougies and follow-through catheters (obtainable from Messrs. Eynard, Paris) invaluable for many cases. Unfortunately, gum-elastic articles do not keep well in the climate of the Central Provinces and they are difficult to sterilize in the out-patient department.

It was with great interest that I read the note by Mr. Milroy Paul in *The Lancet*, of 7th September, 1935, on his urethral bougie and catheter combined.

This set of bougies was made to my design by Messrs. Down Bros., London, to obviate the necessity for passing a metal catheter, in dealing with that common emergency, acute retention of the urine from stricture.

The bougies have the shape of Lister's bougies and, in addition, a narrow channel running through their long axis.

The bougies have proved very satisfactory in practice, as they are passed more easily than a metal catheter owing to their greater weight, better balance and their bulbous ends, and I also prefer to use them instead of a metal catheter in cases of enlarged prostate, where occasionally it is necessary to use a metal catheter to relieve acute retention.

I was about to order a set when I read the note by Mr. Harold Dodd in the *British Medical Journal* on his 'Lister's bougie and dilating sound with Béniqué's curve'.

'In a ten-years' experience of dilatations of urethral stricture I have found that certain obstructions can only be negotiated by a Lister bougie, whilst to pass others the curve of a Béniqué instrument is necessary. In using the otherwise excellent French bougie the absence of the graduated shaft and of the weighted handle of the Lister pattern was repeatedly felt, and out of this arose the idea of combining the two instruments in one in order to secure the advantages of both.

A graduated set made for me by Messrs. Down Bros. and Messrs. Lewis Brothers has the peculiar curve of the Béniqué bougie, with the olive-headed tip neck, tapered shaft, weighted handle, and sizes of the Lister instruments. I have used it regularly for eighteen months and have found that it fulfils its purpose well. It usually "falls in", the dilatation is gradual, and it is effective in passing a tortuous urethra. In addition, it is very useful for determining the potency of the common bile duct into the duodenum, and for stretching the ampulla of Vater.'

As illustrated, Messrs. Down Bros. prepared for me a set from 5/8 to 15/18 combining the ideas of Mr. Harold Dodd and Mr. Milroy Paul (a spigot and stilette are also supplied but are not shown in the illustration). These central-channelled sounds are easily sterilized, they can be used for relieving most cases of acute retention of urine and are suitable for dilating almost every kind of stricture. They should be made of stainless steel. The plated ones are dangerous.

After the sound has been passed and before it is withdrawn the bladder can be filled with antiseptic solution, thus ensuring that the urethra is subsequently flushed with a cleansing substance.

Some cases of retention of urine due to stricture reach the Mayo Hospital after a number of ineffectual attempts have been made outside to relieve the condition. If such cases are at all toxic I find that it is much safer to treat them by means of a Pezzer's self-retaining suprapubic catheter, using a trocar and cannula for inserting it. The self-retaining catheter is left in position until all signs of toxæmia have disappeared and until the stricture has been dilated to size 8/11 English gauge or until the patient commences to pass urine naturally, which he usually does.

D.M., M.A.O. (Dublin Univ.)

8th March, 1939.

AN ENTIRELY NEW FOCAL (WATER-COOLED) ULTRA-VIOLET RAY LAMP—THE KROMAYER LAMP MODEL V

Forty-three years ago Nils Finsen first cured *lupus vulgaris* by focal actinotherapy. The principles on which he worked have since been applied to the cure of many other diseases both of the skin and of the official membranes. Applied at first only by skin specialists, focal actinotherapy has been greatly extended in scope since the introduction of the handy Kromayer lamps, and is to-day used widely in medical practice and dental surgery. Physically considered, the source of radiation required for focal actinotherapy must fulfil three main requirements:—

Intrinsic 'brilliance' of ultra-violet radiation.

As nearly as possible a point source.

Application at the shortest possible distance from the skin.

In all these respects, the Kromayer lamp (Model V) now introduced is a revolutionary advance upon any actinic source hitherto available to the medical practitioner.

This new lamp functions on different principles to any Kromayer lamp hitherto produced. It will operate

freely and with equal intensity in any position—horizontally, vertically (even upside down). The practitioner can thus utilize procedures which were hitherto impossible. Ultra-violet irradiation can be applied through the window or along quartz applicators, to any accessible lesion, with very brief times for application.

It has super-intensity, giving a contact erythema dose within 3 seconds, and a deep therapeutic reaction (fourth degree erythema, or blister dose) within 20 seconds. Its power is so great that the practitioner can select required wave-lengths (using suitable filters) for any application, with ample reserves of energy.

The lamp embodies special provisions to ensure consistency and accuracy in dosage.

A large range of quartz applicators and glass filters are available for use with the new lamp, also a stop-watch for timing exposures. The makers are Messrs. Hanovia Ltd. of Slough, Bucks.

THE 'AGLA' ATOMISER

THE value of an atomiser in which all the parts in contact with the medicament are made of glass is at once obvious. The 'Agla' atomiser, introduced by Burroughs Wellcome and Co., produces an effective vapour-like spray from aqueous or thin oily liquids which come into contact with glass only. The atomiser is so constructed that the larger globules of atomised liquid are effectively retained, so that only the finer spray is emitted. Having a flat base and being fitted with a rubber stopper, the atomiser may conveniently be used as a container for the medicament. When filling the atomiser the level of the liquid should not be more than half-way up the delivery tube. A dropper is provided for transferring medicaments to

the atomiser. The 'Agla' atomiser is of particular value for medication by the oral inhalation method, in which case the patient directs the spray into the open mouth, synchronising deep inhalations with sharp compressions of the bulb. This method is being increasingly employed in the symptomatic treatment of mild or moderately severe asthma, the medicament used being solution of adrenaline, 1 in 100. The 'Agla' atomiser may also be used with advantage for general medication of the nose, throat and upper respiratory passages.

DAGENAN (M. & B. 693)

IMPORTANT PRICE REDUCTION

THE large demand which has followed the introduction of M. & B. 693 (DAGENAN) has enabled the manufacturers to effect a reduction in the selling price of this product.

They inform us that as from Monday, 2nd October, the following prices will be brought into force:

DAGENAN (M. & B. 693)

0.50 gramme

Containers of 25 tablets .. Rs. 5-10-0 each.

Containers of 100 tablets .. Rs. 22-2-0 each.

0.125 gramme

Containers of 25 tablets .. Rs. 3-3-0 each.

Boxes of:

6 × 25 c.c. ampoules Rs. 5-4-0 per box.
20 per cent suspension.

DAGENAN SODIUM

Boxes of:

6 × 3 c.c. ampoules solution Rs. 9-0-0 per box.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

REPORT OF THE USE OF M. & B. 693 IN PNEUMONIA, PNEUMOCOCCAL MENINGITIS, AND PNEUMOCOCCAL EMPYEMA, WITH REPORTS ON TWO CASES OF EXFOLIATIVE DERMATITIS AND ONE OF AGRANULOCYTOSIS DUE TO M. & B. 693

By G. F. TAYLOR, M.A. (Camb.), M.R.C.P. (Lond)
MAJOR, I.M.S.

Professor of Clinical Medicine, King Edward Medical College, Lahore

and

NAND LAL CHITKARA, M.B., B.S.

(Working with a grant from the Punjab Government)

A report of the use of M. & B. 693 in the first 50 Indian cases treated in the Mayo Hospital, Lahore, India, with alternate cases treated as controls, was published in this journal earlier in the year (Chand *et al.*, 1939). The mortality in this small group was 10 per cent in the treated, and 18 per cent in the controls. Only patients who lived longer than 24 hours after admission into the hospital were included in either group.

From November 1938 to the end of June 1939, 159 cases of pneumococcal pneumonia in Indian patients have been treated by this drug in the Mayo Hospital; there have been 11 deaths, a mortality of 6.9 per cent. It is not proposed to publish a detailed report of these cases, as the results agree with those published in other parts of the world, in England (Royal Soc. Med., 1938), Africa (Agranat *et al.*, 1939) and America (Long, 1939).

In this series of M. & B. 693-treated cases, there were four patients who developed empyema in the hospital following pneumonia, *i.e.*, 2.5 per cent, a figure which is not higher than the incidence of empyema in cases treated by methods other than 693.

It was noted that the temperature came down to normal within 48 hours of giving this drug in all but 26 of the 159 cases.

The cause of sustained temperature in these 26 cases was found to be :—

Developing empyema in 4 cases, pneumococcal meningitis in 3 cases, lung abscess, malaria, ankylostomiasis with severe anaemia, tertiary syphilis, 'creeping' type of pneumonia, pre-existing tuberculosis in 1 case each, severe toxicity in 9 patients of whom 5 died, and less severe toxicity in 4 cases in which no obvious cause was found.

From the experience of treating these cases, a complication is suspected if the temperature does not fall within 48 hours from beginning treatment with M. & B. 693. This would seem to be

of particular importance in countries where there is a high incidence of malaria, ankylostomiasis, or other tropical diseases.

Twenty cases showed a rise in temperature after the usual fall to normal. No cause could be found in 6 cases : in the remaining 14 it was as follows :—

Malaria—6 cases, inadequate dose—2 cases, pre-existing tuberculosis, parotitis, jaundice, malnutrition (pellagra), pericarditis, and 'creeping' type in 1 case each.

It has been noted here, as elsewhere, that although the temperature falls to normal, the resolution takes place at the normal time and in the normal manner. The stay in hospital of all cases is reduced by an average of 4 days for each case, an important matter where hospital accommodation is very limited.

Typing by Neufeld's 'Quelling' method and by the agglutination method was begun after 693 had been in use for some months. The following results have been obtained :—

Relation of 693 treatment to types of pneumococci

Type	Number of cases treated	Deaths	REMARKS
I	39	3	All the three cases died of meningitis complicating pneumonia.
II	5	Nil	
Mixed I and II	3	..	
III	4	..	
VI	1	..	
VII	4	..	
Indeterminate group.	10	1	

This work is being continued and results will be published in more detail later.

Pneumococcal empyema

In addition to the four patients noted above, who developed empyema in the hospital, four others have been admitted into the medical wards and treated with M. & B. 693, repeated aspiration, and later by operation. Typing of pneumococci was done by Neufeld's 'Quelling' method and confirmed by the agglutination method. Neufeld's method gave positive results in 6 cases. In one case Neufeld's method gave a negative result, but the agglutination method showed positive type I. Thus, of the 8 empyema cases, 7 were type I, and 1 case was not typed as sera were not available.

Three patients were cured by M. & B. 693 combined with aspiration. In 2 of these cases (cases 1 and 3 of table I) the pus was not thick and aspiration was done only once and twice, respectively. Case 2 had thick pus in the chest, aspiration was done 15 times and a total dose of 85.5 gm. of M. & B. 693 in 30 days was given. In all the 3 cases, skiagram of the chest on discharge from the hospital showed a little

thickening of the pleura. It was decided to treat the other 5 patients by M. & B. 693 combined with aspirations, to avoid the operation of rib resection, if possible.

Although this treatment of repeated aspiration, combined with M. & B. 693 in large doses, was continued for periods up to $1\frac{1}{4}$ months, these efforts were unsuccessful. Four cases eventually came to operation and 1 patient

coccus acquires tolerance to M. & B. 693 within a few days.

Also reports of serious complications of M. & B. 693 treatment, such as agranulocytosis and exfoliative dermatitis, are accumulating. It is concluded that the drug exerts its influence during the first few days of its administration and that it is useless and dangerous to continue its use after four or five days.

* This patient had agranulocytosis and dermatitis exfoliativa.

† Six gm. were given outside the hospital.

In table I as well as in table II severity of the disease was graded as +, ++, +++ and ++++ depending upon the general condition, condition of the tongue, abdominal reflexes at the time of admission to the hospital.

died of agranulocytosis and exfoliative dermatitis; the case notes are given below.

We have concluded from the experience of these cases that when the pus is thin, aspiration combined with treatment by M. & B. 693 is indicated. When the pus becomes thick and loculated, prolonged treatment with M. & B. 693 with aspiration does not clear the empyema and an operation is indicated at an early stage.

These conclusions support the findings of Maclean, Rogers and Fleming (1939) in laboratory animals and Ross (1939) in work on a case of pneumococcal meningitis, that the pneumo-

Pneumococcal meningitis

During this period, 4 of the 139 M. & B. 693-treated pneumonia cases developed pneumococcal meningitis and 13 other cases of pneumococcal meningitis were treated by M. & B. 693 and daily lumbar puncture. Details of these are shown in table II. Of these 17 cases, 3 recovered, a recovery rate of 17.4 per cent. Of these 3 recovered cases, pneumococci were present in the cerebro-spinal fluid (CSF) in 2 cases, in which there had been no previous pneumonia. In the third patient who recovered, a purulent meningitis developed after a type-I

pneumonia; he had been treated by M. & B. 693. The CSF was turbid and contained pus cells but was not under tension. It was concluded that the growth of pneumococci in the CSF had been inhibited by the 693 given previously for the pneumonia. It is debatable whether this case should be included under the heading of pneumococcal meningitis. As yet intrathecal M. & B. 693 has not been given in the hospital.

dermatitis in 693 treatment. We, therefore, report the two following cases:—

Case 1.—Parsee male, aged 30, admitted to general wards of Mayo Hospital on 11th May, 1939. Eleven days previously he had suddenly developed a high temperature with a rigor. A diagnosis of lobar pneumonia of the left lower lobe was made. At the onset he had some bleeding from the nose. As the temperature continued for 11 days, he was sent to hospital for admission. No details of treatment outside the hospital were available.

TABLE II

Additional treatment and notes

- Case 2. Anti-serum, 50,000 units I.
- " " " " 50,000 " II.
- " 6. " " 20,000 " I.
- " " " " 20,000 " II.
- " 14. Prontosil—5 injections.
- " 15. M. & B. 693—4 injections.
- " 16. Pneumococci in sputum. None in CSF (turbid).
- " 17. M., aged 30, came to hospital in comatose condition and died after 4 hours. Pneumococci were present in the CSF. No treatment could be given.

We can only trace 6 cases of pneumococcal meningitis reported in the literature (MacKeith and Openheimer, 1939; Banks, 1938; Cunningham, 1938; Reid and Dyke, 1938) in which recovery occurred after M. & B. 693 treatment.

Agranulocytosis and exfoliative dermatitis complicating M. & B. 693 treatment

Details of 5 cases of agranulocytosis in England (Sutherland, 1939) and one case in America developing as result of 693 have been published, but we have not yet seen reports of exfoliative

The patient was well built and well nourished. He had been a moderate smoker, did not drink alcohol and lived on a good mixed diet including meat.

On examination:—

Tongue furred. Semi-comatose and very toxic. Abdomen distended—constipated. Temperature 100°F., pulse 130, and respiration 34. Consolidation of whole of left lung and some consolidation of right lower base. Blood pressure 128/45. The cause for the low diastolic pressure was not found. White cell count 16,875 per c.mm. Hæmoglobin 95 per cent. He coughed up no sputum.

(It was learnt after the exfoliative dermatitis had developed that he had been given 15 gm. M. & B. 693 in the 11 days before admission to the hospital.)

Treatment.—He was put on M. & B. 693, 4 tablets on admission, 4 tablets after 4 hours, and thereafter 2 tablets 4 hourly, for 36 hours and then 1 tablet 4 hourly.

The temperature was unaltered by this treatment and ranged between 100 and 104.5.

A skiagram taken three days after admission showed a large dense shadow in the left middle zone of the lung, which was thought to be a loculated empyema.

An exploratory paracentesis with a lumbar puncture needle in the seventh intercostal space produced 10 oz. of fairly thick creamy pus.

In this pus, pneumococci were seen on staining. These were typed by the agglutination method and found to be type I.

The white cell count on 16th May was 7,500, with polymorphonuclears 67 per cent, lymphocytes 31 per cent and monocytes 2 per cent.

The general condition had become worse. Because of the low white cell count, M. & B. 693 was stopped. The concentration of the drug in the blood on 13th May was 6 mgm. per cent. The white cell count continued to fall; it was 4,375, 3,125, 5,625 and 2,625 on 23rd May, 25th May, 28th May, and 3rd June, respectively.

A lumbar puncture produced normal CSF.

On 26th May the skin was covered with erythematous blotches which progressed to typical exfoliative dermatitis in which the whole of the skin was shed. Aspiration was done twice more and a few ounces of thick pus removed. As the condition was becoming still worse rib-resection was done on 4th June under local anaesthesia; but the patient died on 5th June.

Pentnucleotide injections were begun on 4th June. It was not available earlier. Unfortunately blood transfusion was not done. A total dose of 38.5 gm. M. & B. 693 was given in 26 days. It was stopped when the diagnosis of the skin condition was made.

Case 2.—Treated in Lahore City by a private practitioner. A Muslim male child, aged 5, suffering from fever, duration 6 months. He had catarrhal signs present in the chest. X-ray showed tuberculous infiltration of the lungs. Sputum was negative for tubercle bacilli. Mantoux reaction was positive. An exact diagnosis was not made. Because of the few pneumococci present in the sputum, he was put on M. & B. 693, 1½ tablets daily for 7 days. After 10 tablets had been given, he developed a morbilliform rash all over the body and high temperature. The drug was continued in spite of the rash which was thought to be measles. The rash progressed to exfoliative dermatitis. The condition became worse and the child died four days after the skin condition developed. The total dose given was 15 tablets, i.e., 7.5 gm., in 10 days. Further details are not available, as neither of us saw the case ourselves.

This case seems to us to show that M. & B. 693 should only be given under strict medical supervision.

Summary

1. In 159 cases of pneumococcal pneumonia treated at the Mayo Hospital, Lahore, 11 deaths occurred, a mortality rate of 6.9 per cent.

(Continued at foot of next column)

M. & B. 693 IN INDIAN STRAINS OF MALARIA

By R. N. CHOPRA, C.I.E., M.A., M.D., S.C.D. (Cantab.), F.R.C.P. (Lond.)

BREVET-COLONEL, I.M.S. (Retd.)

R. T. M. HAYTER, M.B.E., I.M.D.

and

B. SEN, B.Sc., M.B. (Cal.)

(From the School of Tropical Medicine, Calcutta)

For the last few years sulphonamide derivatives have been the subject of intensive study on the part of chemists, experimental pathologists, and clinicians. Prontosil, whose active principle has been shown to be p-amino-benzene-sulphonamide, has proved to be an excellent drug for the treatment of various infective conditions. A number of new compounds have also been produced, whose activity depends on the presence of this molecule, and which have

(Continued from previous column)

2. The causes of the temperature not coming down to normal after 48 hours of giving M. & B. 693 in pneumococcal pneumonia are discussed.

3. It is concluded from the study of the use of the drug in 8 cases of pneumococcal empyema that it is useless and dangerous to continue its use for longer than 4 or 5 days.

4. Seventeen cases of pneumococcal meningitis are reported of which 3 recovered with M. & B. 693 and daily lumbar puncture treatment, a recovery rate of 17.4 per cent.

5. Two cases of exfoliative dermatitis due to M. & B. 693, in one of which there was agranulocytosis, are reported.

Acknowledgments

We wish to thank Lieut.-Colonel Amir Chand, I.M.S., professor of medicine, King Edward Medical College, Lahore, for his collaboration and for allowing us to report on cases treated in his ward, R. B. Dr. Jiwan Lal, professor of pathology, for his help in typing, May and Baker for supplying some of the drug free of charge, and Mrs. Bharucha for supplying funds for buying the remaining quantity of the drug.

been found to possess similar therapeutic properties. With regard to their effect in the treatment of malaria, the views are divergent; for instance de Leon (1937), who was the first to report the effect of prontosil in malaria, treated a number of cases with apparently good results. Other reports have not been favourable (Read and Pino, 1938). Recently, Chopra *et al.* (1939) tested the efficacy of prontosil in human malaria. They found 3 to 4 gms. daily for 5 days possessed an undoubted action in causing disappearance of malaria parasites from the peripheral blood and controlling the symptoms of the disease.

M. & B. 693 is another drug, allied to prontosil, which has also been extensively used by the medical profession in various infective conditions with remarkable success. Recently, Chopra and Das Gupta (1939) tested the efficacy

symptoms, anti-malarial treatment was withheld for a few days in order to select only those cases which did not show any tendency to spontaneous recovery. Approximate estimations of the number of parasites were made daily and the treatment was started when the parasite counts were fairly uniform for two or three days. Daily examinations of blood for malarial parasites were carried out during the course of treatment and also for a few days after the completion of the treatment. The effects of the drug on (1) temperature, (2) the sexual and the asexual forms of the parasites, and (3) the time taken for the disappearance of the parasites from the peripheral blood were studied. Any untoward effects produced were recorded. Whenever possible the patients were kept under observation for a fortnight or so after the treatment was completed and the cultural examina-

† " no "

‡ " parasite-free two days after treatment was finished.

of this drug in monkey malaria. They found that unlike prontosil this compound is capable of destroying the monkey plasmodium (*Plasmodium knowlesi*) in dosage which is even less than what is regarded as the proportionate dose for a monkey as compared with that of man. Moreover, the parasites once disappearing after a five days' course of treatment do not appear again in the peripheral blood, at least in sufficient numbers to be detected in thick films.

In view of the encouraging results obtained with this drug in monkey malaria, we carried out a preliminary investigation in the Carmichael Hospital for Tropical Diseases on a series of cases of human malaria in order to find out how effective the drug is in Indian strains of malaria. The results of this trial have been recorded in the present paper.

The patients were all admitted into hospital and, with the exception of those showing urgent

tions of blood were also carried out in a number of cases to determine if the infection had been eradicated.

The drug was administered by the mouth in all cases. We first started with one tablet (0.5 gm.) three times a day for 5 days, and later increased the dose to 2 tablets four times a day.

The table shows that M. & B. 693 has a mild but definite action on the malaria parasites. In cases of infection with *P. falciparum* the asexual forms disappear from the peripheral blood within three to six days, but the sexual forms remain unaffected (cases no. 2, 3, 5 and 9). In infections with *P. vivax*, both the asexual and the sexual forms disappear from the peripheral blood within three to five days (cases no. 4, 5, 6, 7, 8 and 10). In the case with quartan infection, the parasites persisted for two days after the course of treatment. It

COOLEY'S ERYTHROBLASTIC ANÆMIA

By L. EVERARD NAPIER, M.R.C.P. (Lond.)

J. A. SHORTEN, M.D., B.Ch., M.R.C.P. (Lond.)

LIEUTENANT-COLONEL, I.M.S. (Retd.)

and

C. R. DAS GUPTA, M.B. (Cal.), D.T.M.

School of Tropical Medicine, Calcutta

ERYTHROBLASTIC anæmia, or Cooley's anæmia, is a distinct clinical syndrome that was first described by Cooley (1927) about 12 years ago. Koch and Shapiro (1932) collected 18 cases from the literature and added 5 cases from their own experience. Most of the cases have been reported from the United States and nearly all the patients have been of Mediterranean stock, usually Italian or Greek, but one patient was an English child. We have seen no reference to the incidence of the disease in an Asiatic. The condition appears to have a familial tendency as in 10 of the 23 recorded cases, referred to above, a brother or a sister was also affected.

All the reported cases have been in young children. The first symptom appears in early infancy, in one case there were typical mani-

(Continued from previous page)

is clear from the table that the patients who were given smaller doses of the drug (0.5 gm. three times a day for five days) were relieved of their symptoms and the blood also was negative for malaria parasites, but the patients relapsed during their stay in the hospital. No relapse, however, occurred in those patients who received the higher dose.

A few untoward effects were, however, noticed, but they were of a very mild character. Beyond a slight epigastric distress and flatulence, no toxic effects were recorded.

Summary and conclusions

M. & B. 693 in doses of 4 gm. daily for five days cause disappearance of malaria parasite from the peripheral blood and controls the symptoms of the disease. (2) It destroys both the asexual and sexual forms of *P. vivax*, but only the asexual forms of *P. falciparum*. (3) In smaller doses the symptoms of the disease abated and the parasites too disappeared from the peripheral blood, but recrudescence of the disease occurred within a fortnight. (4) M. and B. 693 undoubtedly possesses mild anti-malarial properties in infection with Indian strains of malaria and is worthy of trial when other anti-malarial drugs are not available, or are contra-indicated. The present series is very small and further investigations are therefore desirable.

festations at 6 months, but the patients are usually about 3 years old before the disease is diagnosed, and they usually die before the age of 10, but Ordway, Gorham and Isaacs (1937) reported a child aged 11 years who was still alive.

Clinical picture.—The patient has a very characteristic appearance: the features are described as Mongolian, on account of the thickening of the cranial bones and of the prominence of the malar eminence. Added to this is a peculiar yellowish muddy tint of the skin. The pigmentary changes which occur are similar to those in hæmochromatosis.

The spleen is always enlarged, usually markedly. The liver is usually palpable and the lymphatic glands are often slightly enlarged.

There are other signs and symptoms of anæmia. There is sometimes high irregular fever, suggesting an acute infectious process, but this is apparently due to the anæmia, as it disappears after blood transfusion.

The disease tends to run a chronic but steadily progressive course. Hæmolytic crises do not occur. Spontaneous fracture of the rarefied long bones has been reported.

Radiological features.—The long bones and small bones of the hand and foot are porous-looking, with sharp trabeculations and thinning of the cortex. The flat bones of the skull show medullary thickening, while the tables are usually thin. The profile of the skull gives the appearance of a surface studded with small radiating spicules (Vaughan, 1934).

The bony changes in the skull are most noticeable in the parietal and frontal bones, to a less extent in the occipital, and are usually absent from the temporal.

These bony changes are said not to be specific and to occur in achloruric jaundice (Friedman, 1928), and in sickle-celled anæmia (Vogt and Diamond, 1930) but we have only seen these extreme degrees of diploic thickening reported in Cooley's anæmia.

Blood picture.—It is a leuco-erythroblastic anæmia. The anæmia is often extreme, and the hæmoglobin may be as low as 1.4 grammes per cent (about 10 per cent Haldane) with the red cells at about 1,700,000 per c.mm.; that is to say, it is a hypochromic anæmia. The most striking feature in the blood picture is the large number of nucleated red cells, mostly normoblasts; there are frequently more nucleated red cells than leucocytes. There is usually a persistent leucocytosis of about 13,000 to 20,000 per c.mm. with only a few immature cells. Despite the hypochromia the mean red cell diameter is said to be about normal, but there is a high coefficient of variability. This is well shown in the Price-Jones curve of the case of Moncrieff and Whitby (1934), but the curve given by Vaughan (*loc. cit.*) shows a low variability.

The van den Bergh reaction is positive and the icterus index high. There is a considerable increase of urobilin in the urine.

Fig. 1.

Fig. 2.

Fig. 4.—Antero-posterior: plate in nose-forehead position. Fig. 5.—Antero-posterior: plate in nose-chin position.

In the bone marrow there is leuco-erythroblastic hyperplasia. There are numerous primitive cells of the erythrocyte series, but not many normoblasts, nor myeloblasts; there are usually a number of megakaryocytes. There is a considerable increase in the hæmopoietic bed.

Nature of the disease.—Erythroblastic anæmia is apparently a primary dysfunction of the blood metabolism, probably congenital, in which the hæmolysis is a secondary factor (Cooley and Lee, 1932). The cells formed by the marrow are defective and probably qualify more quickly than ordinary red cells for normal hæmolysis.

Differential diagnosis

Osteitis deformans (Paget's disease).—This is only mentioned because it was actually suggested, surprisingly by a radiologist, although every radiological feature is against this diagnosis. In Paget's disease, the cortex of the bones is widened and encroaches on the medulla; the regular bone lamellar structure is replaced by a solid mass of varying density; and there is irregular alternation of sclerosis and areas of rarefaction.

Added to this, osteitis deformans does not appear before the age of thirty and usually much later, and there are no characteristic blood changes.

Sickle-cell anæmia.—In this disease, in addition to the abnormality in shape of the blood cells, hæmolysis is the most important feature, and the hyperplasia, which is orderly, is only the result of a demand to compensate for the excessive hæmolysis; there is a high reticulocyte count but not a great number of normoblasts.

Congenital hæmolytic anæmia and achloruric jaundice.—The state of affairs is much the same as in sickle-celled anæmia, but whilst the cells are of normal shape they are more fragile.

Von Jaksch's disease.—Cases of Cooley's anæmia have undoubtedly in the past been included in the von Jaksch syndrome, but Cooley differentiated this disease by the very striking bony changes, by the lower leucocyte count and the very small number of immature cells, and by the greater number of normoblasts.

Case note

The patient attended the anæmia out-patient department of the Calcutta School of Tropical Medicine, where a provisional diagnosis of Cooley's anæmia was made by the junior writer (C. R. D. G.), and the child admitted into the Carmichael Hospital for Tropical Diseases under the charge of the senior writer (L. E. N.).

Hindu male, aged 10 years, weight 40 lb., height 3 feet 9 inches, the first-born child of healthy parents, belonging to a cultivator family living near Calcutta. He has two healthy younger sisters, aged 5 and 3 years, respectively.

He is said to have had a big head since birth. He was quite well up to the age of about 7 years when he had low intermittent fever associated with enlarged spleen and liver; for this he was treated with nine intravenous injections—probably antimony—with partial success, inasmuch as both the spleen and the liver were diminished considerably in size, and the

fever came only in bouts at intervals of several days and was shorter in duration and not as high as before.

For the last 15 days his parents had noticed the yellow coloration of the eyes and therefore brought him to the hospital.

The peculiar facial expression, the unusually big head (figures 1 and 2), the yellow tint of the conjunctivæ struck one immediately.

On examination the boy appeared to be anæmic. The pulse was soft and fast, 110 per minute. The tongue was clean, teeth good and there was no bleeding from the gums. No abnormality was detected in the heart or lungs. The abdomen was protuberant, the spleen was $4\frac{1}{2}$ inches and the liver about $1\frac{1}{2}$ inches below the costal margin. There was no œdema of the lower extremities. The knee jerks were normal and there were no sensory disturbances.

Laboratory findings

Blood.—The blood picture showed a microcyte hypochromic type of anæmia with a high reticulocyte count (7 per cent). The differential white count showed 59 per cent of polymorphonuclears, 36 per cent of lymphocytes, 1.5 per cent of large mononuclears, 1.5 per cent of eosinophiles, 1 per cent metamyelocytes, and 1 per cent neutrophil myelocytes. Normoblasts numbered 34 per 100 leucocytes.

At a subsequent count (1st September) the large mononuclears had increased to 6 per cent and the eosinophiles to 10 per cent at the expense of the polymorphonuclears.

There was marked polychromasia.

Other details of the blood counts are given in the table I.

Price-Jones curve (figure 3).—Mean diameter— 6.56μ . Standard deviation— 1.02μ . Co-efficient of variation—15.5 per cent. Mean corpuscular thickness— 2.17μ .

Fig. 3.

Van den Bergh—direct—negative, indirect—3.5 mgm. per cent.

Fragility of red blood cells. Beginning of hæmolysis at 0.4 per cent solution; complete hæmolysis at 0.3 per cent solution.

28-9-39	8.80	4.10	15.0	29.5	71.9	21.4	29.8	18,144	1.5	4

Coagulation time—3 minutes by the capillary method.

Wassermann reaction—negative.

Cholesterol—120 mgm., and serum calcium—11 mgm. per cent.

Sternum puncture.—The bone felt as if there were a thin shell surrounding soft, almost fluid, tissue; the needle after piercing this shell encountered no resistance. The puncture material showed a very active marrow, with a total nucleated count of 383,500 per c.mm., which was markedly normoblastic—with a fair number of macroblasts. Further details are given in table 2 below.

Gastric analysis.—Free hydrochloric acid was present in the fasting juice in normal amounts (\approx 20 c.cm. N/10 HCl). The boy would not keep the tube down and no further samples were taken.

Urine.—Urobilin markedly increased; no other abnormality.

Stool.—Normal. No helminthic ova nor protozoa seen.

Treatment.—Ferrous sulphate, grs. 6, twice daily was given for three weeks from 29th July to 20th August, and liver extract (Lilly) 2 c.cm. on 2nd, 3rd and 4th September.

The hæmoglobin percentage increased after the iron administration, but showed no further improvement when liver was given. A transfusion of 200 c.cm. of blood was given on 22nd September. The improvement in the blood picture was only slight.

STERNAL PUNCTURE IN KALA-AZAR

By D. GOVINDA REDDY, M.D.

and

R. SUBRAMANIAM, M.B., B.S.

(General Hospital, Madras)

A NUMBER of publications dealing with sternal puncture in the diagnosis of kala-azar have appeared in the past few years. Unanimity of

(Continued from previous page)

vault affecting the diploic layer and the outer table mainly. The inner table does not appear to be affected. The thickened bone shows vertical striations throughout. There are no areas of sclerosis and rarefaction, such as are seen in Paget's disease.

These changes are practically confined to the frontal, parietal, and occipital bones. The temporal and facial bones appear to be normal, except for evidence of the general osteoporosis mentioned below.

The bones of the spine, pelvis, limbs, and extremities show a generalized halisteresis (figure 7) with marked thinning of the cortex and destruction of some of the trabeculae, giving rise to a stippled appearance of the cancellous tissue, quite different from the appearances seen in Paget's disease.

There are no cystic formations, bending of the weight-carrying bones, nor pathological fractures.

Summary and conclusions

The clinical picture, the blood findings and the radiological features conform more closely to the published descriptions of Cooley's anaemia than to those of any other disease.

The patient is older than is usual in this disease, but is not the oldest case reported. We do not know of any previous report of an authentic case of Cooley's anaemia in an Asiatic.

opinion with regard to the value of the method is, however, lacking.

Vaughan (1938) states that parasites in leishmaniasis may be demonstrated more readily in smears of sternal marrow than by any other method.

Napier (1938, 1939) in a long series of cases found the method useful but inferior to splenic puncture.

We have been carrying out sternal puncture with Salah's needle as part of routine investigation of anaemia in the wards of the professor of medicine, Madras Medical College, for some months and have taken the opportunity of investigating 11 cases of kala-azar.

In two cases, prolonged search of several slides (extending over two hours) failed to reveal the presence of Leishman-Donovan bodies. The parasites were readily demonstrated in splenic puncture.

The table gives the list of the findings in these cases.

In most cases the findings of leishmania in the marrow smears was a time-consuming and tedious process, whereas the parasites could readily be found in splenic puncture.

Although leishmania bodies were scantily present in the marrow smears of cases 10 and 11, spleen punctures were made for demonstrations to the class, and the difference in the ease of finding the parasites was very striking.

In case 9, the diagnosis depended on spleen puncture. A male Hindu, aged 25, from an endemic area. History of fever of 14 days' duration. The spleen was just palpable. The aldehyde and antimony tests were negative. Sternal puncture negative, after prolonged search. Spleen puncture showed numerous parasites.

Summary and conclusions

In a small series of cases it was found that in 2 patients suffering from kala-azar, leishmania bodies were not demonstrable in sternal puncture though abundant in splenic puncture.

The method is time-consuming and tedious, although safer and requiring less preparation and after-care than splenic puncture.

A negative sternal puncture should therefore lead to spleen puncture in doubtful cases with equivocal biochemical reactions.

Our thanks are due to Lieut.-Col. G. R. McRobert, I.M.S., Professor of Medicine, Madras Medical College, in whose wards the investigations were carried out.

EARLY SCHIZOPHRENIA

By M. TAYLOR, M.D., D.P.H.
MAJOR, I.M.S.

Medical Superintendent, Ranchi European Mental Hospital

In these days the constant stream of writings on schizophrenia has served to indicate the rapid progress which is being made in this field of psychiatry. The introduction of cardiazol and insulin therapy constitutes a unique scientific revolution in an age of revolutions. The statistics of any mental hospital will bring home to the serious thinker the vast importance of schizophrenia. The schizophrenic-reaction types constitute over fifty per cent of the population of these hospitals, and, measured by the loss of time and money, it would be almost impossible to estimate the morbidity of the disease. The reports of practically all mental hospitals invariably reveal the fact that the vast proportion of the schizophrenics who come to hospital are well advanced in their psychosis, and, in many cases, so far advanced that a hopeless prognosis is inevitable.

The medical student fortunately need no longer look for his psychiatric material exclusively in the mental hospital. There is a movement which is slowly gaining impetus to handle some of our psychiatric problems in general hospitals, in the schools, and in the courts. The student will soon discover that a great number of diseases, which begin strictly as problems of general medicine, soon overflow into the channels of psychological medicine. Take, for example, typhoid fever. There are, in this condition, certain symptoms which cannot be measured by

observation, palpation, percussion, or auscultation, nor by the test-tube nor microscope. These symptoms may be defined as the reaction of the individual to the infecting organism. In bedside teaching the student will frequently complain that the patient is not like the general descriptive picture in the textbook. The complete clinical case is rare in reality, and in the schizophrenic-reaction types, the most difficult psychoses to comprehend, he will find it extremely hard to identify early evidence of the disease.

In the present decade the treatment of schizophrenia by cardiazol-convulsion therapy has been extensive in all European and extra-European countries, and statistics of some 5,000 cases which have been collected, indicate that full remissions can be achieved in 50 per cent of recent cases (duration of illness 12 to 18 months), and a point of no little economic importance is the shortened sojourn of patients in hospital. All authorities are agreed that the prospects of success diminish in ratio with longer duration.

There is no short road to the understanding of human reactions, and it is only after years of training and experience that the physician can deal adequately with personality disorders. The recognition of incipient schizophrenia is however becoming increasingly important to the general practitioner. Numerous excellent books on the subject are available, some dealing with Indian conditions, but their size and price place them beyond the scope of the average private library, and it is with this consideration in mind that I propose to attempt to set forth in simple

language some of the symptoms of early schizophrenia.

Cameron (1938) in a recent and excellent paper on early schizophrenia, gives two tables on the behaviour changes in schizophrenia. In the first table he enumerates the non-specific early symptoms in terms as used by the relatives. The symptoms are divided into two main groups—those characterized by the hypofunction, and those in which hyperfunction was dominant.

TABLE I

Non-specific early symptoms

Terms used by relatives to describe patients' behaviour synonymous terms in parenthesis.

Elements of a hyperactive pattern

Nervous (restless, tense)	Moody
Sleepless	Impatient
Worried (uneasy apprehensive)	Tantrums
Nightmares	Fault-finding
Hypochondriasis	Moralizing
Somatic complaints	

Elements of a hypoactive pattern

Seclusive (withdrawn, quiet)	Depressed.
Day-dreaming	Lack of energy
Pre-occupied	Lack of concentration
Loss of friends	Fatigue (weariness).
Irritability	Poor appetite
Loss of interest (of ambition)	

In the second table he enumerates what he describes as the early specific schizophrenic symptoms.

TABLE II

Early specific schizophrenic symptoms

Talked about	Ideas of disgrace
Watched	Idea of redemption
Doped	Supporting hallucinations
Fears of violence	

GROUP (II)

Ideational responses

Somatic experiences	Psycho-somatic experiences
Dazed	Screaming and giggling
Dizzy	Speech tantrums.
Lack of feeling of familiarity	Failure to co-operate in eating, talking or moving
Odd somatic experiences	

It is generally recognized that there are four types of schizophrenia—simple, hebephrenic, catatonic and paranoid, but transitions from one clinical form to another are common.

(1) The simple types are characterized by defects of interest, gradual development of an apathetic state, often with peculiar behaviour, but without expression of delusions or hallucinations.

(2) The hebephrenic types show a tendency to silliness, smiling, laughter, grimacing, mannerisms in speech and action, and numerous peculiar ideas usually absurd, grotesque and changeable in form.

(3) The catatonic types display a prominence of negativistic reactions or various peculiarities of conduct with phases of stupor or excitement, the latter characterized by impulsive, queer or stereotyped behaviour and usually hallucinations.

(4) The paranoid cases are characterized by a prominence of delusions, particularly ideas of persecution or grandeur, often connectedly elaborated, and hallucinations in various fields.

The following are illustrative cases taken from the notes of four early cases which came under my care in the Ranchi European Mental Hospital.

Case 1.—Male, Indian, aged 19, early schizophrenia (simple).

Family history.—Father and mother alive and in good health, three brothers had brilliant university careers and hold good appointments. One sister in good health and is married. No insane, epileptic, or intemperate relations known.

Personal history.—Seen January 1938. Bacillary dysentery at the age of 4; tonsils removed five years ago; nothing else important.

Physical condition.—Good, nothing important abnormal.

Wassermann reaction negative.

Onset.—The father, a very intelligent man, could give a very typical history of early simple schizophrenia. He stated that the boy had entirely changed during the past six months. He did very well at school and matriculated in the first class, and was attending university. His habits were solitary and seclusive and he studied or appeared to study very hard—did not play any games, nor did he mix with individuals of his own age. He became bad tempered, irritable, and had fits of depression, could not concentrate on his studies and became quite apathetic. There were occasional attacks of excitement, after which he was confused. He became emotionally dull, and lost all affection for the members of the family. His ambition went, and he gave no thought for the future.

Mental examination.—Appeared indifferent to his surroundings, facile, and showed no gross oddities of behaviour. Perception and cognition were good, and the memory both recent and remote was fairly good. No delusions, no hallucinations. Mild ideas of reference; thought people talked about him, and were passing remarks that he was not as good as his brothers, and that he was 'no good' for anything. Could discuss politics and knew all the famous political men. Says he was a student when a student, but was no longer a student and objected to work in the occupational therapy department—could not concentrate on jig-saw puzzles. This is a fairly typical case of early simple schizophrenia. The course in the hospital was uneventful. The patient co-operated well and was discharged recovered after six months' treatment.

Case 2.—Female, aged 23—European—schizophrenia (hebephrenia).

Family history.—Bad: Father a drunkard; divorced; mother married a second time, was unable to give any family history regarding the patient's father, but stoutly asserted that there never had been any insanity in her own family. The patient was the only child of the first marriage. The first child of the second marriage is an imbecile. The second child reported to be normal, and doing well at school. The patient had always been pampered and had had her own way, but all seemed to be well until the step-father fell in love with her. The home thereafter provided an excessively erratic environmental condition, and the mother made the shocking statement that the step-father had made immoral advances to the girl. So bad did matters become that the patient was sent to live with another family as a boarder. The mother continued 'It was out of the frying pan into the fire' for

the man in the new household also 'took advantage' of the patient on many occasions. This will suffice to indicate the circumstances under which the patient was brought up. She went to work as a typist—fell in love with her employer, and left, as there was no reciprocation. On arriving home her behaviour became very queer, and she developed odd delusions. Was brought to hospital for examination.

Mental examination.—She appeared precocious, defiant and self-assertive. An ardent conversationalist, but refused to give any co-operation while 'that woman' (referring to her mother) was in the consulting room. The mother withdrew. She then proceeded—'This brain (pointing to her forehead) was one of the best in the world at one time; now, it is empty; it will not function'. 'A nerve in my right arm has gone red-hot and has stopped the brain from functioning. My blood is all wrong; it is not circulating properly. It was such a good brain, and it is all his fault. I cannot tell you; it is all too horrible. This is a dreadful body of mine, but I cannot help myself'. On being pressed as to whose fault it was. She assumed the dramatic and said 'my step-father'. 'Since I was eleven years old he has almost daily handled my private parts. He has taught me sex perversion and I cannot help myself. It's sadism!'

There had undoubtedly been a bad moral history, bad sex practices, and perversions from an early age. There had been imperfect control all through adolescence. She formed liaisons with married men and would not listen to reason. Very definite mental conflicts about sex experience and her misbehaviour, but a complete absence of remorse. She says 'I'm modern and broad-minded'. The lack of success in her 'amours' is probably projected on to the step-father. Inhibition appears at times when she becomes emotional. Highly erotic.

Course in hospital.—Showed more or less emotional disturbance, but the mental ability was fair. Lodged many false complaints about cruelty. Conduct eccentric and the somatic delusions remained persistent for some time. Made a complete recovery after four months' treatment.

Case 3.—Male aged 28—European—early schizophrenia (catatonic type).

Family history.—One sister in a mental hospital. Seven sisters normal, one brother normal. Father and mother alive and well.

Personal history.—Normal birth and development, brilliant school and college career. Occupying a good position.

Physical condition.—Excellent physique, and nothing abnormal in any system, beyond constipation.

Personal history.—Was on duty until a few days before admission. There was a sudden burst of uncontrollable excitement in a busy street. He emerged from a shop where he had been conducting some business. He believed the passers-by were reading his thoughts and that they knew all his past history. Ran wildly up and down the street until he was taken for observation. Certified. On admission depressed, emotional, suspicious, and the certificates noted strong suicidal tendencies. Answered questions with much reluctance, but volunteered a statement that he was under the influence of the devil. Kept muttering 'Oh, Jesus Christ, have mercy on me'. Questioned further, he said, I am a very wicked man, and it is best that I should die'. After sedative treatment for a few days he became more communicative. His intellectual faculties were quite clear and he co-operated well in the examination. There were distressing sexual thoughts, syphilophobia, and feelings of shame. Stoutly asserted that he had never had sexual connection. There had been obvious failure to adjust his somatic and psychic sexuality, and he had been for some time ruminating over his habit of masturbation till the feelings of guilt became no longer bearable. Soon after this he had a relapse—asked the ward-boy for some vaseline—and there was shameless and frequent masturbation. Later, became depressed—the castration complex was present. He jumped out of bed, injured his scrotum to the effusion of blood and attempted to

injure his genitals. Reacted well to hydrotherapy. Acute mental distress developed, intense anxiety, and all sorts of phobias. Nocturnal frights became frequent, and he would wake up screaming, thinking he was in hell. The chaplain was asked to pay him visits, and these helped considerably. He displayed at this time alternate outbursts of maniacal excitement with fits of depression. He tried all sorts of devices to commit suicide, and it became necessary to place two attendants on him night and day. Hydrotherapy and sedation were given and a course of pyretotherapy (sulfosin) was commenced. Auditory and visual hallucinations to which he reacted were persistent. The voices he heard were extremely abusive. He would pray for long periods on end. He had very good reactions with the sulfosin and he gradually showed improvement. He was able to be out of doors and could take mild exercise. He soon discussed his conflicts, and the antics and cowering which were formerly present ceased. He now took his food well—although previously it was frequently necessary to resort to tube feeding. The mental state fluctuated, but he never really got out of his depression. At times there was anxiety and reticence, and he confessed to fearful ideas of reference, and very strong homosexual components. Would ask odd questions—such as why are nipples put on men, and why do pubic hairs grow on men? (he always shaved his pubic hairs). He told me at this period that he had been worried because there had been a rent in his camp bed and he felt sure some of his friends had put a wrong construction on this. A friend visited him at this time, and he was permitted to go for a motor ride with him. A very bad reaction resulted; on return from this outing he made a dash for the vegetable garden and made for one of the wells. Frustrated. Aggressive and resistive, but was persuaded to return to his room. Sedatives and rest in bed for some days with only slight improvement. Agitated, suspicious, and kept repeating 'I cannot understand it all'. Delusions of unworthiness and strong suicidal tendencies present. Continued to have very good reactions with sulfosin and again showed signs of improvement. Co-operation became excellent and he looked forward to psycho-therapeutic sessions. Commenced occupational therapy, and took a keen interest in the social side of the hospital activities. Soon took up the threads of his past—got in touch with his bank, and wrote long and interesting letters to his relatives. A complete review of his personal difficulties from an early age was begun, and gradually extended to a frank discussion of his delusions previous to admission.

Brought before the visitors' committee and was discharged. He asked permission to remain in the hospital as a voluntary boarder and was later granted leave by a medical board. After a complete rest in the United Kingdom he was able to resume his duties and has remained well for over two years. Duration of stay in hospital—five months.

Case 4.—Male, aged 30, early schizophrenia (paranoid type).

Family history.—Unobtained.

Personal history.—Brilliant school career. Did very well at the university. Was holding an important post. Towards the end of 1938, his work commenced to deteriorate, his memory became faulty, and he could not concentrate. Early this year he had an outburst of excitement with confusion. Certification was necessary. On admission his general attitude was suspicious, and he resented being questioned. There was no co-operation for a week, when he suddenly said to me 'I think I can trust you, but I shall require at least an hour to tell my story'. I arranged to meet him the following day. He was obviously in a state of panic. Commenced to give his life history from childhood. Nothing really important as regards illness. Whooping cough and scarlet fever in childhood. Harbours a strong resentment towards his father. Was his mother's favourite. Oedipus complex was unduly strong. Became sexually aware of himself at the age of 12. Had flirtations at school. Masturbation ++ from an early age. Admitted that he is an overt

homosexual. His homosexual tendencies are abhorrent to him, and have caused him a good deal of worry for a considerable time. Thought his weakness became known to some of his friends, there were ideas of reference, and he was being tortured by abusive voices. The voices he heard were not but that he had special powers.

He could transmit and receive messages from friends in Southern India by telepathy, etc., and remarked—'Don't run away with the idea that you are talking to a lunatic'. 'Let me tell you something'—'It was predicted by a Madame Blatavski that a certain person would be born—he would get an important post in India, he would pass through a period of tribulation, but that he would become the greatest man in the world'. (This person is himself.) He is full of his own importance, and says it will not be long before his powers will enable him to have direct telepathic communication with the Secretary of State for India. Went on to tell me that he had been a great social success, and that his charming manners and his ability to engage in clever conversation had made him very popular, and his presence at dinner parties always thrilled the whole company. Started writing lengthy letters to various high officials indicating that he would in due course be taking over a very important appointment. Soon became extremely suspicious of everyone. Complained that his letters were being read, and others not delivered; that his personal property was being interfered with, and that everyone in the hospital was conspiring against him. Completely devoid of insight. Would leave various articles lying about the room and then check them up, accusing the wardboys of stealing; would burn his letters in the boiler fire and then lodge a complaint that they had been removed from his room. Got a padlock and locks his room if he leaves it for a minute. Delusions became very prominent. The water and food were poisoned. He drew a tumblerful of water from the tap. Remarked 'Can't you see this water is all wrong. The specific gravity is too great—the water is oleaginous; it is poisoned'. I said 'let me have it, I'll drink it'. 'No, no', he replied, 'you would be dead in two minutes'. Threw the water away. Auditory hallucination continue to be persistent, and he was in daily communication with many people. Gave a lot of trouble with his food, became most inconsiderate to the staff, and if his wishes were not immediately complied with would demand that the superintendent be summoned immediately. Lodged many false complaints, and when investigations were made, would withdraw the charges verbally or in writing, and express regret. Proud, sensitive and still very suspicious, walks about the hospital with a very superior air, and reminds all that he is a superior individual. Demanded an interview from the committee of visitors. This was granted. Very annoyed because they did not issue orders for his immediate discharge from hospital (he is well conversant with the Lunacy Act). Made several attempts to abscond. Writing bombastic letters to his people, asking them to send full particulars regarding the 'family crest', etc., adopting an air of exaggerated dignity and condescension, and has become very aggressive to the staff, assaulted some of the wardboys. The mental condition continues to deteriorate, auditory hallucinations and delusions of persecution remain persistent. Says he is being impersonated and that his signature is being forged on cheques. Told me that I was being impersonated, and to be on my guard, etc.

The case illustrates a fairly typical case of the paranoid type of schizophrenia. Psychoanalysts find a homosexual trend in most patients who develop a paranoid state. The patient is still under treatment but the prognosis is not considered good.

The schizophrenic reaction types constitute beyond question the most important group of the psychoses. The notes from the case histories

LUNG ABSCESS

By MANGALDAS J. SHAH, M.B.C.P. (Lond.),
D.T.M. & H. (Lond.)

King Edward VII Memorial Hospital, Parel, Bombay

Introduction.—There are many points in the ætiology and treatment of lung abscess that are still not fully understood. Hence, the writer decided to study the records of the cases of lung abscess admitted and treated at the King Edward VII Memorial Hospital, Parel. The material consists of fifty consecutive clinical cases of lung abscess.

Hippocrates thought that lung abscess was caused by inhalation of blood and mucus, and that spontaneous recovery occurred on its rupture into a bronchus. In the 16th, 17th and 18th centuries, operation and drainage, through the intercostal spaces, were reported by eminent surgeons. Trousseau (Lockwood, 1923) was alone in advocating palliative measures in this era of radical surgery. This surgical mindedness towards lung abscess held the field till Murphy in 1898 analysed the position of surgery and exposed the defects and limitations of surgical treatment; since the day of Murphy, lung abscess is looked upon as a medical disease, requiring expectant treatment in the majority of cases.

There is no clear agreement even as regards the clinical definition of a lung abscess, since there is no distinct line clinically dividing lung abscess from lung gangrene. Some treat these two conditions as different clinical entities. Kline and Berger (1935) distinguish abscess from gangrene by the character of the sputum. They state that in abscess the sputum is whitish yellow, purulent, and contains pyogenic organisms, while in gangrene the sputum is brownish, very offensive and contains anaerobic spirilla, *B. fusiformis*, etc. Others depend upon

given illustrate the characteristic symptomatology. Early diagnosis and treatment may prevent an unfavourable outcome.

It is difficult to deal with such a vast subject within brief compass, but those who wish to venture further into the study of schizophrenia will find any of the following textbooks of great value :—

Textbook of Psychiatry—Bleuler.

The Principles and Practice of Neurology—(Cannon and Hayes).

Essentials of Psychiatry—(Henry).

Textbook of Psychiatry—Henderson and Gillespie.

A Manual of Mental Diseases—Lodge Patch.

REFERENCE

Cameron, D. E. (1938). *Amer. Journ. Psychiat.*, Vol. XCV, p. 567.

the pathological fact that an abscess is a collection of pus, while gangrene is a massive destruction of lung tissue. Clinically, the difference is only one of degree. Any circumscribed collection of pus in lung tissue, exclusive of pulmonary tuberculosis and bronchiectatic accumulations, is a lung abscess.

Ætiology

(a) *Age*.—The following is the age distribution in the present series of 50 cases :—

Years	Cases	Years	Cases
5-9	1	30-39	18
10-19	2	40-49	11
20-29	12	50-59	4
		60-63	2

The youngest case was of a boy aged 5 years and the oldest of a man aged 63 years. Out of 50 cases, 41, i.e., 82 per cent, fall within the age period 20 to 49 years.

Léon-Kindberg (1928) reported that 70 per cent of his cases were between the ages of 20 to 45 years; while Lockwood (1923) gave the greatest incidence of lung abscess between 25 to 40 years.

(b) *Sex*.—Out of 50 cases only 5 were female patients, showing a proportion of 9 males to 1 female. Léon-Kindberg reports a ratio of 3½ males to 1 female.

(c) *Site and distribution*.—The distribution in the present series was as follows :—

There were 5 cases of multiple abscesses and 45 of a single abscess. Of 45 cases, 31 occurred on the right side, and 14 on the left, giving a proportion of $\frac{\text{right}}{\text{left}} = \frac{2.2}{1}$. In the 45 cases of a single abscess, in 30 cases the abscess was located in the lower and in 15 cases in the upper lobe. Eleven abscesses were at the right apex and 4 at the left. Léon-Kindberg's report shows that there are 2½ times more cases on the right than on the left and that the location at the bases is 4 times more frequent than at the apices. Probably the preponderance on the right side is due to the anatomical relation of the right bronchus to the trachea.

(d) *Cause*.—In the present series the causes may be classified as under :—

A. Primary	21	cases	42	per cent
B. Secondary	29	"	58	"
1. Pulmonary infection (influenza, bronchitis, broncho-pneumonia, lobar pneumonia).	21	"	42	"
2. Chest trauma ..	2	"	4	"
3. Empyema ..	2	"	4	"
4. Aspiration ..	2	"	4	"
5. Embolic ..	2	"	4	"
(i) Cellulitis foot.				
(ii) Unknown.				

This grouping of causes has been arrived at after consideration of the history, physical signs and post-mortem evidence.

Flick, Clerk, Funk and Farrell report 172 cases of lung abscess, out of which 121 were post-operative, 43 were due to acute respiratory infection and 8 followed miscellaneous causes like injury, drowning and poisoning. According to Ascoli and Bonadies (1932) 50 per cent of lung abscess in the United States of America were post-operative. Most of the English authors state that the incidence of post-operative lung abscess is much less in Great Britain than in America.

The incidence in the present series is interesting in the fact that not a single case followed operations on the throat or mouth, in spite of so many throat and mouth operations being performed at the K. E. M. Hospital. Moore (1922) gives an incidence of 1 abscess in 2,500 tonsil operations, while Glowacki (1923) quotes an incidence of 1 in 356 tonsillectomies. General anaesthesia was used in these reported cases. At Mayo clinics where 16,000 tonsillectomies were performed under local anaesthesia only, 2 cases of lung abscess occurred. It may be justifiable to state that lung abscess following throat and mouth operations are not so common in Bombay. The reason for this difference from the experience in other institutions may be an inadequate follow-up of cases after operations, or to the fact that the difference is real and the incidence is really low. This difference can only be explained by further observations by operating surgeons. It may also be that the incidence from causes other than post-operative is greater than in the United States of America or in Great Britain.

Twenty-one cases out of 50, i.e., 42 per cent, have been reported as primary lung abscess in the present series. By primary abscess is meant that the first evidence of a morbid process is a suppuration in the lung tissue. Léon-Kindberg (1928) states that 50 per cent of his cases are primary lung abscess. In the primary lung abscess, perhaps some septic material passes down from the mouth to the throat and to the bronchus or bronchiole and sets up a suppurative process in the lung tissue. This inference of septic aspiration becomes more plausible since the micro-organisms, detected in the pus of lung abscess, resemble the normal aerobic and anaerobic bacterial flora of the mouth.

Twenty-one cases out of 50, i.e., 42 per cent, of the present series followed some pulmonary infection, such as influenza, bronchitis, or broncho-pneumonia. There are only 5 cases in which abscess followed lobar pneumonia. In the series reported by Flick, Clerk, Funk and Farrell, 43 cases out of 172 were due to an acute respiratory infection, 22 followed cold, 16 pneumonia, 2 broncho-pneumonia and 2 acute pleurisy. Edwards (1938) states that he has never seen a pneumococcal abscess following a pneumococcal pneumonia.

In the present series no serious attempt was made to study the predominant types of micro-organisms which were detected in the sputum.

However, in the few cases where a post-mortem examination was performed the following organisms were reported to be present :—

(1) Streptococci, (2) Pneumococci, (3) Staphylococci, (4) *B. pyocyaneus* and (5) *Bacillus fusiformis*.

Clinical

The mode of onset depends on the cause of the lung abscess. In primary cases the onset is sudden with fever, cough, with or without expectoration, hæmoptysis, and often pain in the chest. In post-pneumonic cases, the consolidation does not resolve and the fever persists. In one of the cases in the present series fever came down by crisis, remained normal for 4 days, and later developed into a septic type of temperature. In post-operative cases the patient develops fever, cough, pain in the chest, expectoration, hæmoptysis, and a leucocytosis after a lapse of about seven days. The sputum becomes abundant and foetid on about the 14th day. In the present series patients on admission to the hospital complained of the following symptoms, in order of their frequency :—

1. Fever	..	49 cases (1 case was afebrile).
2. Cough	..	42 "
3. Foetid sputum	..	29 "
4. Pain in chest	..	13 "
5. Hæmoptysis	..	12 "
6. Dyspnœa	..	5 "

Cough is perhaps the commonest symptom that draws the attention to the disease process in the lung. In the early phases, the cough is dry and unproductive, and is due to the irritation of the bronchi. A sudden severe paroxysm of cough may be the first indication of the bursting of an abscess into the bronchus. The paroxysms of cough may be repeated several times a day, particularly on change of posture, which causes some of the pus from the abscess cavity to flow down into a healthy bronchus and set up a reflex cough.

The expectoration in early phases consists of slight muco-purulent material from the bronchi. When the abscess opens into the bronchus, the material expectorated is frankly purulent. The foetid character of the pus depends on the presence of anærobic bacteria, e.g., *B. fusiformis*, Vincent's spirochaetes, etc., which may be the primary organisms, or the secondary invaders of the lung abscess.

Pain in chest depends on the peripheral situation of the abscess, due to an involvement of the pleura in the inflammatory process. The character of the pain is that of a pleural pain.

Hæmoptysis seems to be a common symptom of lung abscess. In the present series 12 patients (24 per cent) complained of coughing up of blood. Léon-Kindberg (1928) reports the presence of hæmoptysis in 24 per cent of his cases. In the early phases, hæmoptysis is due to a congestion round the inflammatory process.

Later on, it is due to an involvement of the blood vessels in the inflammatory process and their destruction.

Dyspnœa is usually present as a sign of general toxæmia but in some cases it is due to an involvement of a massive portion of the lung tissue.

Signs

There are no physical signs absolutely characteristic of the disease. The physical signs in a case of a lung abscess depend entirely on the situation of the abscess. In the case of a hilar or central abscess, there may be no physical signs, while in the peripheral sub-pleural abscess the local signs may be marked. Hence, physical signs by themselves have little value and should be interpreted in conjunction with other findings. The physical signs will be general and local.

The general signs noted in the present series are :—

(1) Fever. The height and range of fever varied from case to case. In a majority of the cases the fever was remittent or intermittent.

(2) Leucocytosis. A polymorphonuclear leucocytosis was observed in the majority of cases, where a leucocytic count was made. The highest count recorded is 30,000 white blood cells per c.mm. while the lowest was 3,900 per c.mm. The latter figure shows that in some suppurative processes an increased leucocytic response may be absent.

(3) Clubbing of fingers. Marked clubbing with drum-stick fingers is present in many cases.

The local pulmonary signs.—The following were noted during the examination of the case :—

(1) There were no signs of a localizing value in 12 cases. There need not be any localizing sign if the abscess is central or hilar.

(2) Signs of congestion and exudation in the alveolar spaces, as evidenced by an impaired note to percussion, with deficient breath sounds, were present in 16 cases.

(3) Signs of consolidation, that is, impaired resonance to percussion and bronchial or tubular breath sounds, were noted in 19 cases.

(4) Signs of cavitation, that is, impaired note to percussion and cavernous breath sounds, were noted in one case. The fact that the signs of cavitation were present in one case only is not surprising in view of the fact that an abscess cavity, as different from a bronchiectatic cavity, does not completely evacuate its contents into a bronchus.

(5) Signs of diffuse patches of consolidation were present in two cases.

(6) A pleural friction rub could be demonstrated in cases where the pleura is involved in the inflammatory process.

(7) Sputum.—The sputum derived from the bronchi during the first few days is small in

amount and muco-purulent in character. From the 10th to 14th day, a sudden large amount of expectoration is brought out, a fact indicating that the abscess has burst into a bronchus. The quantity brought out varies according to the size of the abscess cavity, and the frequency and the completeness of evacuation. The colour of the sputum is pale green, greenish brown, or black. The consistency may be thin or tenacious. Odour is foul and offensive in a majority of cases. On keeping the sputum in a conical glass, it separates into three layers, froth at the top, watery fluid in the middle, and sediment of pus and strands at the bottom.

X-ray.—There is no characteristic shadow by which lung abscess may be recognized. In the majority of cases there is a round shadow with a fluid level. In some cases an abscess cavity may be obscured by pneumonitis around it. If the pleura has been thickened, the abscess may be obscured and there may be a shadow with diffuse margins. Hence the interpretation of the radiological findings is to be utilized for confirming the diagnosis arrived at after a careful study of the history, the physical signs, and an examination of the sputum. In order to localize the site of the abscess, it is desirable to have both antero-posterior and lateral views. Such a localization of the abscess is very necessary in deciding the line of treatment to be adopted.

Lipiodol is not very useful since it does not fill the abscess cavity, but passes into other surrounding bronchi in the majority of cases.

Bronchoscopy may help in the diagnosis of a lung abscess following bronchial carcinoma or stenosis. It may also help to localize the abscess in relation to the bronchi.

Course and mortality

It is very difficult to arrive at a definite conclusion regarding the mortality rate, or recovery rate, from a small series of 50 cases. Out of the 50 cases, 20 died in the hospital. Out of these 20 deaths 3 died within 24 hours after admission (mortality of 34 per cent). Twenty-one cases are noted to have clinically recovered. Some of these recovered cases were controlled radiologically. The remaining 9 cases left the hospital against medical advice.

Summary

(1) Clinical records of 50 cases of lung abscess which were admitted at the King Edward VII Memorial Hospital, Parel, Bombay, are analysed.

(2) Though lung abscess is a common disease the above records do not show even a single case following operation on the nose, throat and mouth in contradistinction to the figures that are reported in American and English journals, where a high percentage of lung abscess following operations on the tonsils and upper respiratory tract are reported.

STUDY OF DIET IN TWO INDUSTRIAL AREAS IN ASSAM, WITH SPECIAL REFERENCE TO THE INCIDENCE OF ANÆMIA*

By DURGA DAS MITRA, M.Sc., M.B., D.P.H.

The present dietary investigations were undertaken at the suggestion of Dr. L. E. Napier, Professor of Tropical Medicine, School of Tropical Medicine, Calcutta. Hæmatological studies had already been carried out at Labac (Cachar) and Jorehaut (Upper Assam) by Napier and Majumdar (1938) and Napier and Das Gupta (1937), respectively, among a number of women belonging to families of industrial workers in several tea-gardens; the object of the study of their diet was to find out if any correlation between the diet and these hæmatological findings existed.

Diet survey

Diet survey was done in 37 families in Labac (Wilson and Mitra, 1938) during July and August 1937 and in 35 families in Jorehaut during March and April 1938. The cases in which the hæmatological studies were carried out by Napier and his co-workers came either from some of these families or from others of similar status and dietary habits. Diet survey was carried out for periods of three weeks in every case, information about dietary intake being obtained daily by house-to-house visits. Average consumption of the more important

*This paper was read at a meeting of the Physiological Society of India on 17th March, 1939.

(Continued from previous column)

I take this opportunity to thank Dr. Jivraj N. Mehta, the Dean of the King Edward VII Memorial Hospital, Bombay, for permitting me to go through the records of the hospital cases.

My thanks are also due to the honorary staff members who were in charge of these cases. I thank Professor Khanolkar for his help and guidance. I must particularly thank Dr. Namjoshi, a house physician, for his sincere and untiring help.

foodstuffs per consumption unit per day was as follows :—

TABLE I

	Labac (Lower Assam)	Jorehaut (Upper Assam)
Rice (parboiled and mostly milled).	19.0 oz.	19.4 oz.
Pulses	1.0 "	0.9 "
Non-leafy vegetables ..	3.4 "	4.4 "
Leafy vegetables ..	0.2 "	0.8 "
Fish, eggs and meat ..	0.2 "	0.7 "
Mustard oil	0.3 "	0.3 "

Average intake of proximate principles, calories, minerals and vitamins per consumption unit per day (table II) have been calculated on the basis of the figures given in the *Health Bulletin* (Aykroyd, 1937) with the exception of vitamin B₆ and flavine, for which figures of Wilson and Roy (1938) have been used.

TABLE II

Average number of persons and consumption units per family, an average intake of proximate principles, calories, minerals and vitamins per consumption unit per day

Place of survey and number of families	Labac (Cachar), 37 families	Jorehaut (Upper Assam), 35 families
Number of persons	3.5	4.9
" " consumption units	2.5	3.5
Protein—total protein (g.) ..	58.8	63.8
" animal " (g.) ..	1.6	4.6
Fat—total fat (g.) ..	12.0	13.4
" animal " (g.) ..	0.4	0.9
Carbohydrate (g.) ..	458	497.9
Calories—total calories ..	2,181	2,329
" percentage from cereals.	88.9	86.5
Mineral matter—		
Total minerals (g.) ..	6.77	10.43
Calcium (g.) ..	0.17	0.27
Phosphorus (g.) ..	1.67	1.77
Ratio Ca : P ..	1 : 9.6	1 : 6.6
Iron (mg.) ..	18.77	27.79
Vitamins—		
Vitamin A (I. U.) ..	23	17
Carotene (I. U.) ..	995	1,593
Vitamin B ₁ (I. U.) ..	624	687
Flavine (mg.) ..	1.074	1.139
Vitamin B ₆ (rat units) ..	279	305
Vitamin C (mg.) ..	26	67

These average figures show that the animal protein, total fat (including animal fat), calcium, and vitamin A (including carotene) are deficient when compared to some recognized standards (table III).

The Ca:P ratio also appears not to be suitable for the proper absorption of either, and the dearth of fat in the diets seems to make it still more difficult for the already insufficient vitamin A and carotene to be properly absorbed. The vitamin-C figure refers to raw uncooked food, and therefore the amount actually consumed in the cooked food is doubtful; also the intake of raw fruits or vegetables is negligible.

Total iron and 'available' iron

'The iron in certain foods is less "available" than the iron in others' (Aykroyd, 1937). The available iron figures have been calculated (table IV) according to Ranganathan's data (1938).

Table IV shows that not a single family in Labac and only one in Jorehaut consumes iron, anything up to Sherman's (1937) standard of 12 mg. On the whole, the diets appear to be definitely deficient in available iron.

Further, many poor people in those areas cook their food in earthenware vessels; this prevents any accretion of iron to the cooked food, which, though uncertain in amount, does occur when iron pans are used. The health of the women is more adversely affected than that of the men, on account of the physiological factors of menstruation and pregnancy, the latter is repeated in many cases at short intervals in those areas.

This deficiency of 'available' iron entirely tallies with the findings of Napier and his co-workers. In fact, in Labac, the population of pregnant tea-garden coolie women, as a whole, were observed by them to have a low level of hæmoglobin, associated with a small pale red blood cell, and in Jorehaut, in 100 cases of anæmia studied by them, there was no case of the pernicious type, and with very few possible exceptions, they were all cases of the microcytic, hypochromic, iron-deficiency type.

Discussion

The absorption of iron depends on the acidity of the gastric juice, but in Jorehaut, Napier and Gupta (*loc. cit.*) found the incidence of achlorhydria lower in the anæmic group than in the normal population. Thus this point may be ruled out in the present case.

Orten, Smith and Mendel (1935) showed that an increased intake of calcium improved the utilization of iron in normal blood formation, and the deficiency of calcium in the present diets may be another factor at fault in relation to anæmia.

Copper again helps utilization of iron in the body (Barer and Fowler, 1937; Hutchison, 1938; Canelli, 1937), and Napier used ferrous sulphate with minute quantities of copper sulphate added, for the iron therapy (private communication). No definite figures for copper are, however, known as yet for the common Indian foods.

Several cases of goitre were seen in Jorehaut, which possibly indicate a deficiency of iodine in

the water and/or soil. Deficiency of vitamin C and thyroxine are believed to cause general slowing of hæmopoiesis and may be partly responsible for the degree of anæmia in the present cases.

Napier showed that the blood picture in microcytic-hypochromic anæmia could not be improved by dietetic treatment alone, an observation corroborated later by Davidson and Fullerton (1938) who pointed out the importance of dietary iron in prophylaxis against anæmia but showed that this iron was not curative in 11 anæmic cases.

Summary

Dietary investigations were carried out amongst 37 families at Labac (Cachar) and 35 families at Jorehaut (Upper Assam) to find out if any correlation existed between the diet and the microcytic-hypochromic type of anæmia observed by Napier and his co-workers in those areas. The data on diet, when worked out, showed a great deficiency in available iron.

Acknowledgments

I thank Dr. L. E. Napier for making the arrangements for these diet surveys and Doctors G. Fraser and D. Manson, the chief medical officers at Labac and Cinnamara (Jorehaut), respectively, for whole-hearted co-operation and facilities during the field work.

A DIET SURVEY IN BOMBAY

By S. P. NIYOGI, M.Sc., M.B.

Professor of Physiology, Seth G. S. Medical College, Parel, Bombay

and

D. R. SUKHATANKAR, M.Sc.

(From the Department of Physiology, Seth Gordhandas Sunderdas Medical College, Parel, Bombay)

THE present survey has been undertaken to obtain an idea of the food consumed by people resident in Bombay and to investigate their physical and clinical condition in relation to diet. A knowledge of the qualitative and quantitative composition of food is obviously essential for the proper application of the result of nutritional science to the practical problems of dietetics.

In this country a number of diet surveys have been carried out in different provinces. Wilson, Widdowson and Wait (1937) have worked on families in Northern India; Wilson, Ahmad and Mullick (1936) have surveyed some families and institutions at Calcutta. Aykroyd and Krishnan (1937) investigated some poor families in Southern India; Ahmad and Gore (1938) and Wilson and Mitra (1938) carried out a survey of some poor families in Ferozepore, Assam and Baraset, respectively. A diet survey of various classes of women in Bombay was made by Wills and Talpade (1930). It may, however, be stated that there is still a large mass of material available in Bombay which demands a more extensive dietetic and clinical survey for the guidance of life both in health and disease.

Subjects surveyed

The present communication deals with 46 poor class families consisting of 191 members, 16 middle class families comprising of 77 members and 6 different messes attached to the Seth G. S. Medical College and K. E. M. Hospital, Bombay, consisting of 223 persons. The enquiry is being continued in the poor, middle and rich class families belonging to different communities and useful information can only be obtained after an extensive survey has been made.

It has been found convenient to classify the families and messes that have been investigated into groups according to the amount of money spent on food per man value per month (table

I). Groups (I to V) are poor families having an average monthly income varying from Rs. 36 to Rs. 55. Families in group I come from Gujrat districts. The male and the female members in the majority of cases are in municipal service employed as sweepers. The members of families in groups II and III belong to Poona and Konkan districts. Male members are employed as office peons, or laboratory servants and the women folk in some of the families work in the mills. Group IV comprises members of Christian and Mohammedan communities and are employed as butlers in messes or as ward-boys in the hospital. Group V consists exclusively of Hindoo male members from northern parts of India. They are employed in the hospital as ward-boys and sweepers.

Groups VI and VII include middle class families with an average monthly income varying from Rs. 120 to Rs. 135. The male members are employed as clerks in the offices of the Seth G. S. Medical College and the K. E. M. Hospital. The six vegetarian families of this group are Deccanics and the remaining ten non-vegetarian families include Deccanics and Indian Christians. Groups VIII to XIII are the messes attached to the Seth G. S. Medical College and K. E. M. Hospital, Bombay. The students, resident medical staff and the nurses of the above institutions belong to different communities having separate messing establishments as shown in table I. The students draw an average monthly allowance of about Rs. 40 for boarding, lodging and pocket expenses. As regards the nursing and resident medical staff arrangements are made by the hospital authorities for free board and free quarters with uniform allowance in the case of the former, while the resident medical officers are also supplied with free quarters having a mess of their own. In the case of these staffs there can be no relationship between emoluments and amount spent on food as, while the grades of their respective salaries may be different, the food served in the respective messes is identical for all the members of each mess according as they are vegetarians or non-vegetarians.

Dietary habits

An idea of the dietary habits can be obtained from the figures given in table II.

Groups I to V.—The cereals consumed by these groups are rice and wheat. A few families take *javari* and *bajri* in addition. It will be seen from figures given in table II that the cereal food consumed by group I consists of rice and wheat, that by groups II, III and IV is composed chiefly of rice and that of group V consists chiefly of wheat. Pulses form the chief source of protein in the diet, meat, fish, eggs and milk being taken sparingly except by the Christians, Mohammedans and the Hindoos from provinces other than Bombay. The fats are

derived mostly from vegetable oils, the consumption of ghee being insignificant. Fourteen out of the forty-six families investigated in these groups take no milk, while 20 families consume less than 4 ounces of milk per adult per day. Vegetables figure largely in the diets, although fruits are conspicuous by their absence.

Groups VI and VII.—The cereals and pulses used are of the same type as in groups I to V, but their consumption is in most cases less than in the latter groups. In the non-vegetarians of the group the intake of meat, fish, and milk products is higher than in the corresponding groups of poor families. The consumption of large quantities of milk by the vegetarians of this group is a characteristic feature. The quantity of oil and ghee is slightly in excess as compared to that in the diets of poor families. Fruits are not usually taken, but vegetables are

taken in the same proportion as in the poor family diets.

Groups VIII to XIII.—The various items entering into the composition of these diets are the same as in groups VI and VII, but these diets contain larger quantities of pulses and animal foodstuffs, such as meat, fish, eggs, milk, ghee and a liberal supply of vegetables and fruits.

Experimental

The survey of each individual family or mess was carried out for seven days. It is proposed to repeat the investigations in different seasons of the year in order to get an idea of any dietetic variations with seasonal changes, when different types of foodstuffs are available. The raw rations were weighed twice during the day before the two principal meals. The values for

the different proximate principles were calculated from the data given in *Food* by McCarrison (1920). The wastage before cooking and after service was analysed in the laboratory, and due allowance made for the daily loss. In the majority of the families, the wastage was negligible as the food left after one meal was utilized for the following meal. In the messes investigated wastage and leakage, specially of costly items of food, were by no means insignificant. The intake of minerals has been determined by actual analysis of cooked food in the physiological laboratory of the Seth G. S. Medical College. The family coefficients for finding out the consumption units are those suggested by the League of Nations (1936). The validity of the family coefficient method of assessing the family needs has been questioned by several observers, but the method is so convenient and useful that it cannot be discarded until a more scientific one is evolved. In the survey lasting for seven days, it so happens that some members of a family are absent from one or more meals and sometimes one or more visitors are at the house to participate in the meals. In calculating the consumption per man value, cognizance has been taken of the meals missed and of the extra participants.

Results and discussion

It will be convenient to give a summary of the results obtained and to discuss the points of interest in detail.

Protein.—The protein consumption is shown in table III. There is a good deal of controversy regarding the protein requirements of an

with higher protein content, are healthier and of better physique than those subsisting upon a more restricted protein intake. The British Medical Association Committee recommended 100 g. of protein of which 50 g. should be from animal sources. The Ministry of Health Committee has suggested an intake of 100 g. of total proteins and 37 g. of animal protein. The true protein intake of an average man in the tropics may be taken as midway between the two extremes and should vary from 70 g. to 100 g. of which 37 g. should be derived from animal sources. Judged from these standpoints the diets of the vegetarian families of the poor and the middle classes are deficient in the total proteins. This deficiency is all the more marked because the protein derived from the vegetable sources have a lower biological value and are less readily absorbed and assimilated than the animal proteins.

In all the diet groups except XII and XIII there is a deficiency of animal proteins. The inadequacy of the total proteins and animal proteins becomes less marked with increasing expenditure on food. The amount of protein consumed per man value per day is lowest with the smallest income groups and highest with the largest, but the amounts for the intermediate income are more or less the same.

Fat.—The fat intake per consumption unit per day is given in table III. The fats, quite apart from the fact that they furnish the fat-soluble vitamins, are essential elements in nutrition. Fatty foods contain besides neutral fat and fat-soluble vitamins, other substances which cannot be apparently synthesized in the

TABLE III

adult. Upon an ordinary mixed diet containing proteins of varying biological values, nitrogen equilibrium can be maintained on an allowance of 40 g. to 50 g. for a man of average weight. According to McCay the diets of the Japanese and the hardier races of India contain a greater quantity of protein than the minimum prescribed by Chittenden. McCay is of opinion that the tribes in India, which are accustomed to diets

body. Burr and his associates are of opinion that linoleic and linolenic acids are essential for normal nutrition and cannot be synthesized in the body. This view has not, however, met with universal acceptance. Another advantage of fat is its staying power. Its digestion is extended over a larger period than that of carbohydrates. Hunger, emptiness, and fatigue are experienced much sooner upon a diet rich in

carbohydrate than upon one containing a liberal supply of fat. The amount of fat consumed varies with the country, economic status, occupation, and season. The maximum fat content of the native diets of Japan is about 30 g. The Inter-allied Food Commission adopted 57 g. as the minimum fat ration during the war. The accepted standard of fat requirement in the western countries is 100 g. per day of which 50 g. is animal fat. The actual requirement for tropical countries has not been worked out, but it is probably not advisable to take less than 80 g. of total fat and 40 g. of animal fat daily. In poor families (groups I to V) the total fat and animal fat consumption is inadequate. The diets of the middle class families (groups VI and VII) contain sufficient amounts of total and animal fats and the institutional diets are rich in both of these items. With the rise of income there is a definite increase of fat consumption. Cathcart and Murray (1932) have reported a

body. It will appear from the figures given in table III that the carbohydrate consumption is within normal limits in groups II, III, IV, V, XI, XII and XIII; high in group X and low in groups I, VI, VII, VIII and IX.

Minerals.—The mineral intake is given in table III. The calcium intake is low in the diet of groups I to V. The Ca/P ratio in these diets is ill-balanced; this can be attributed to low consumption of milk and cereals, such as wheat. The Ca/P ratio is well balanced in all the other diet groups. Most cereal phosphates are present in an unassimilable condition in the form of inositol hexaphosphate. As the cereal consumption is not very high in the diets that have been surveyed, there is probably no risk of a concealed P-deficiency and consequent derangement of the Ca/P balance. The intake of iron appears to be adequate in all the diet groups but all the iron consumed may not be present in an ionizable and assimilable form.

TABLE IV

Group	PERCENTAGE CALORIC DISTRIBUTION IN THE DIET						VITAMIN CONTENT OF THE DIET						Per cent increase in weekly growth of rats

XIII	4,334	11.9	46.2	41.4	29.2	29.0	1,819	5,195	3,117.0	621	4,800	240.0	20.1

similar increase of fat intake with increase of income in certain families in Cardiff and Reading. The dietary rules for the use of fatty foods are quite simple, for most of the people are aware of the disadvantages of too fatty a meal. It is always desirable to take heavily-fatted foods in moderation. In the case of institutional diets the excessive fat consumption may, however, be more apparent than real, as it is sometimes difficult to obviate the possible chances of leakage of butter and ghee which constitute rather costly items of the diet.

Carbohydrate.—The carbohydrate intake in grammes per man value per day is given in table III. Carbohydrates being cheaper than proteins and fats, there is naturally a tendency, especially among the poorer classes, to increase the proportion of carbohydrates in the diet beyond the amount which is desirable. When a large proportion of the food is in the form of carbohydrate, the intake of fat or of protein is likely to be less than the nutritive needs of the

Calories.—Percentage calorie distribution in the diets is given in table IV. Although the actual protein intake in most cases is found to rise with the increase of income, the percentage of energy derived from protein sources is more or less identical in all the diet groups, and moreover this value is in most cases definitely below the accepted standards. The percentage of calories derived from fat is the highest with the largest income and lowest on the smallest income. With the increase of income there is a steady fall in the energy intake from carbohydrate sources. The calories derived from the milk and milk products are adequate in all the groups except in groups I to V and VII, in which they are low. The cereal calories are rather high in groups I to V. With rising income there is not only an increase in the total calories ingested but there is a more marked rise in the consumption of fat.

Vitamins.—The figures for the vitamin contents of the diet groups are given in table IV.

The values are taken from the *Health Bulletin* No. 23 (Aykroyd, 1937). The figures refer to the amount present in the edible portion of the uncooked food. For products that are cooked or otherwise treated proper allowance is to be made for the loss of vitamins. It is difficult at the present time to lay down authoritatively the minimal or optimal requirements of vitamins at different ages, but certain comparative statements can be made from the figures given in table IV. The diets of groups I to V are deficient in vitamin A and carotene, as compared to those of other groups. Vitamin B₁ appears to be adequate in all the groups. Vitamin-C content of the diets of groups I to VII is low in comparison to what is present in other diet groups.

Economic status in relation to diet

One of the most important tasks for people of small or moderate incomes is to know how to meet their nutritional needs at as low a cost as possible. Simple wholesome foodstuffs can be secured for a moderate expenditure, but it is just as true that good quality proteins in the form of milk, eggs, meat, and mineral and vitamin containing foods in the form of fruits require money. To buy expensively does not necessarily mean that one is getting the best in the physiological sense. The quality and quantity of food consumed are not therefore always dependent on income. It will be seen from table I that the percentage of income spent on food steadily diminishes with increase of income. With increase in the purchasing power only a part of the extra income is utilized in remedying the dietary deficiency; the greater portion is apparently spent towards improving the other items in the standard of living. Moreover, the extra money is not utilized to the best advantage, as is clearly seen in the ill-balanced diet of the masses where a liberal allowance is available for the purchase of proper materials in suitable amounts and proportions.

Rat growth tests

The weekly increase in the rate of the growth of rats fed on average samples of the different diets is shown in table IV. The average weekly rate of growth of albino rats on an adequate and well-balanced diet has been found to be 25 per cent of the body-weight.

Assessment of the state of nutrition

In the absence of adequate standards of height and weight for the various classes of the Indian community it is extremely difficult to make a correct assessment of the state of nutrition. A comparison of weight averages of groups of men with corresponding averages of European or American standards, might give some idea of the relative state of nutrition of the groups. In our measurements the weight of an individual of a particular age and height has been taken and compared with the weight of an American of the same age and height and the

percentage deviation of weight above or below the standard has been calculated. The results have been combined and the percentage deviation above or below the standards for all the persons in the groups obtained, the data for men, women, and children being treated separately. For each person the Pelidisi, hæmoglobin percentage, blood pressure (systolic and diastolic), vital capacity, and dynamometer grips have also been taken and the averages for the group worked out; these results are given in table V. The percentage incidence of deficiency and other diseases is shown in table VI.

Conclusions

(1) The average diet of the lowest income groups (I to V) is adequate in calories, deficient in the percentage of milk and milk product calories, rich in cereal calories. The diet is poor in total and animal proteins and also in vitamin A, carotene, and vitamin C owing to a deficiency of protective foods.

(2) The diet of the next income groups (VI and VII) is adequate in energy value, but poor in total and animal proteins.

(3) That of the third groups (VIII to XIII) is ill-balanced, having a high energy value and a high fat content.

(4) The increase in the intake of total calories and fat calories with a rise of income is very well marked, whereas the protein calorie consumption is more or less the same at all income levels.

(5) The physical condition of the subjects as far as it can be judged from the body-weight, Pelidisi and hæmoglobin percentage shows an improvement with increase of income.

(6) The results of the feeding experiments clearly show that most of the diets are incapable of ensuring adequate growth in albino rats.

(7) The survey reveals that the defective diet is not solely the outcome of a lack of means and the majority of people investigated irrespective of their income are living on an inadequate or ill-balanced diet.

(8) So far as can be judged from the physical and clinical survey of the small number of subjects investigated there is some evidence of under-nutrition, although there are no clearly manifest signs of deficiency and other diseases.

Acknowledgments

The authors are indebted to Dr. Jivraj N. Mehta for interesting himself in this investigation, for securing the funds needed for the enquiry and for his encouragement which he has given freely. Their best thanks are due to Mr. R. G. Chitre for rendering valuable technical assistance in the initial stages of the enquiry, to Drs. Miss P. Daruwalla, Miss J. Hakim, Miss Patankar, J. Mordecai, A. K. Boman Behram and P. L. Pawar for carrying out the medical inspection, and to the households and institutions that tolerated the visits of the workers and co-operated in the conduct of the survey.

THE SEROLOGICAL TYPES OF VIBRIOS ISOLATED FROM CHOLERA PATIENTS IN CALCUTTA

By C. L. PASRICHA

MAJOR, I.M.S.

M. N. LAHIRI

P. C. DAS

and

B. M. PAUL

(From the Cholera Bacteriological Enquiry, Indian Research Fund Association, School of Tropical Medicine, Calcutta)

VENKATRAMAN and Pandit (1938) have recently reviewed the literature bearing on the serological types of *Vibrio cholerae* and the few observations on the types of vibrios in relation to different epidemics. These workers record a severe epidemic of cholera in Periyakulum range of the Madura district in South India. They examined stools from 131 cases of cholera and studied 84 strains of vibrios isolated from 97 cases. These 84 strains of vibrios were all of the Ogawa type.

Maitra, Sen Gupta and Thant (1938) examined 52 agglutinable strains of *V. cholerae* isolated in Rangoon, and found that 51 of these strains were of the Inaba type and only 1 strain of the Ogawa type.

During the year ending 28th February, 1939, the stools from 959 clinical cases of cholera were examined. Vibrios were isolated from 438 or 45.7 per cent of the patients examined. Biochemically all the O-agglutinable strains were

arabinose-negative and belonged to Heiberg's groups I and II. The serological type was determined by agglutination test with rabbit sera prepared with Bruce-White's standard dried Inaba and Ogawa 'O' antigens and with a living suspension of *V. cholerae* (Inaba). The results are given in table I.

The Inaba O and Ogawa O sera used were completely differential and the agglutination with these sera was to titre. The titre of the different sera with their homologous strains were, Inaba 'O' —2,500, Ogawa 'O' —1,000 and Inaba 'H & O' —2,500.

The Inaba type of *V. cholerae* was isolated from 60.7 per cent of the bacteriologically-positive cholera cases. The Ogawa type was found in 25.8 per cent of such cases. The Ogawa type of *V. cholerae* was present throughout the year, and there was no appreciable preponderance of the Ogawa type at any particular time of the year or the cholera epidemic.

The H-agglutinable vibrios, i.e., vibrios inagglutinable with Inaba O or Ogawa O sera but agglutinable with Inaba H & O serum, were found in 2.8 per cent of the patients from whom vibrios were recovered. The inagglutinable vibrios were found in 10.7 per cent of the cases.

Summary

The types of vibrios isolated from the stools of 959 patients suffering clinically from cholera have been studied. The Inaba type was found in 60.7 per cent of the cases, the Ogawa type in 25.8 per cent, H-agglutinable vibrios in 2.8

TABLE I

The serological types of vibrios isolated from cholera patients in Calcutta during one year ending 28th February, 1939

Year	Month	Number of cases examined	Bacteriologically-positive cases	SEROLOGICAL TYPES			
				Inaba	Ogawa	Hagg ¹	Nagg ²
1938	..	March	162	78	12	..	12

BACTERIOPHAGE IN AN EXPERIMENTAL INFECTION IN MICE

By C. L. PASRICHA

MAJOR, I.M.S.

Professor of Bacteriology and Pathology

and

S. LAL, M.B., B.S.

Research Worker, Indian Research Fund Association

(From the Department of Bacteriology and Pathology,
School of Tropical Medicine, Calcutta)

It has been claimed by several workers that bacteriophage exerts an important influence on the epidemic spread of infection. Greenwood, Hill, Topley and Wilson (1936) examined several reports of the use of bacteriophage in the ward, in the field, and in animal experiments carried out in the laboratory. Their critical survey does not support the many favourable reports that have been made or the reasons advanced from time to time for the failure of bacteriophage therapy or prophylaxis. They state that so far as their experience is concerned the dream of bacteriophage as the ideal agent for the control of epidemic disease still remains a dream. These workers however do not think that this field has yet been explored to the point at which further research becomes useless, and advocate the use of controlled animal experiments rather than the relatively uncontrolled trials in the field. The present paper deals with experiments carried out in 1936 and are recorded because the results show that bacteriophage produced a definite delay in mortality.

The experiment was carried out in mice and the organism used was a strain of *Bacterium paratyphosum B* the virulence of which had been enhanced by repeated passages through mice. The bacteriophage used was a mixture of different races of bacteriophage and produced a rapid and complete lysis of the test organism. At the beginning of the test each mouse received 1 c.cm. of a young broth culture containing 6,000 million organisms per c.cm. This was given conveniently with a 2-inch needle attached to a syringe. The end of the needle had been made blunt and thickened into a bulbous tip. The animals were then divided into two groups—one group received bacteriophage, 1 c.cm. of which was given soon after the culture, a second and a third dose of 1 c.cm. bacteriophage was given at two-hourly intervals. Thereafter, one dose

of bacteriophage (1 c.cm.) was given daily as long as the animal was alive. The control series received broth (in doses of 1 c.cm.) instead of bacteriophage used in the test series. The selection of the animals into the two series was left to chance. The animals were given the culture and then divided into two groups.

The experiment was carried out with a small convenient number of animals. For the sake of brevity, the results of the different experiments have been consolidated. The results of the individual experiments were almost identical. Sixty-eight mice were used in the test series and a similar number in the control series.

Days after the administration of the culture that the animals died	Number of deaths amongst 68 mice. Each mouse received $6,000 \times 10^6$ <i>Bact. paratyphosum B</i> by mouth	Number of deaths in the test series of 68 mice. Each mouse received $6,000 \times 10^6$ <i>Bact. paratyphosum B</i> by mouth followed by bacteriophage

Died later	3	4

Post-mortem examination and blood culture was made in each animal. The test organism was readily recovered from the blood of all animals after death except in a few animals that died during the night and were putrefied.

The results of this experiment show no difference in the eventual mortality in the two series but they do show a definite delay in the mortality. There are 21 deaths in two days amongst 68 mice in the control series whereas there are only 8 deaths in the bacteriophage series in the same period. This difference is of statistical significance. After the first two days there were no deaths in the control series for three days but deaths continued to occur in the bacteriophage series. Later on, there is no real difference in the mortality in the two series. No satisfactory explanation can at present be advanced for the high mortality in the control series in the first two days after oral administration of *Bact. paratyphosum B* and no deaths in the following three days. This was repeated six times with similar results. A few deaths continued to occur in the phage-treated series.

THE INCIDENCE OF MONILIAS IN HUMAN FÆCES

By C. L. PASRICHA

MAJOR, I.M.S.

Professor of Bacteriology and Pathology
and

S. LAL, M.B., B.S.

Research Worker, Indian Research Fund Association
(From the Department of Bacteriology and Pathology,
School of Tropical Medicine, Calcutta)

ASHFORD (1917) and a number of subsequent workers regarded monilias, particularly *Monilia psilosis*, as the cause of sprue. Several species of the genus *Monilia* have been implicated in the causation of sprue and this disease was at one time regarded as moniliasis of the digestive tract. Although the result of recent work has shown that this view is no longer justifiable, there is a tendency for some authors of books on tropical diseases to ascribe a certain rôle, often secondary, to these fungi in the causation of sprue. Mackie and Chitre (1928) in Bombay examined the stools of 71 sprue cases and of 76 individuals who were not suffering from sprue for the presence of monilia. These workers found monilia as frequently in other intestinal diseases and in healthy men as in sprue, and concluded that there was no evidence to show that any of the yeasts studied by them had any causative relation to sprue. It was thought desirable to repeat this work in Calcutta.

Stools from healthy individuals and from individuals suffering from diseases other than sprue were examined for the presence of monilia. The methods employed were similar to those used by Mackie and Chitre and consisted in the isolation of the yeast on Sabouraud's medium. An attempt was made to classify into different species, the monilias isolated, but the results obtained after a study of 40 strains were so confusing that it was thought that no useful purpose would be served by proceeding with the

(Continued from previous page)

Summary

The mortality in mice after the oral administration of *Bact. paratyphosum B* is given. The mortality in another series that received bacteriophage following the oral administration of *Bact. paratyphosum B* is compared.

Although there was no difference in the final mortality in the series that received bacteriophage there was a definite delay in mortality in the animals that were given bacteriophage.

Med. Res. Council, Special Rep.
Ser., No. 209, p. 179. His Majesty's Stationery Office,
London.

identification of the individual species. The results of this examination are given below :—

Total number of individuals examined = 220
Number of individuals from whom various species of monilia were isolated = 144 or 65 per cent

(A) According to race and diet.

(1) Number of Indians on Indian diet examined = 146
Number from whom monilia were isolated = 106 or 73 per cent

(2) Number of Europeans on European diet = 76
Number from whom monilia were isolated = 39 or 51.3 per cent

(B) According to state of health.

(1) Number suffering from intestinal diseases (but not sprue) = 60
Number from whom monilia were isolated = 45 or 75 per cent

(2) Number not suffering from any apparent intestinal disease = 160
Number from whom monilia were isolated = 99 or 62 per cent

The number of monilia colonies present in each plate were counted. Twenty or less colonies were considered as scanty isolation, more than twenty colonies as abundant. The results obtained in healthy individuals, in those suffering from acute intestinal fluxes and in those suffering from chronic or vague intestinal disturbances are summarized in table I.

TABLE I

Showing the number of colonies isolated from the stools of individuals suffering from acute and chronic intestinal disturbances and from apparently healthy individuals

Clinical	Number of individuals in whom monilias were found	PER CENT CASES IN WHICH MONILIAS WERE ISOLATED	
		Scanty, 20 or less colonies	Abundant, more than 20 colonies
Healthy individuals. No intestinal disturbances.	99	37	63
Acute intestinal fluxes.	9	33	67
Chronic intestinal disturbances.	51	34	63

IMPORTANCE OF CHEMICAL TESTS FOR DETECTION OF SEMINAL STAINS IN MEDICO-LEGAL INVESTIGATIONS

By RAJ BAHADUR K. N. BAGCHI, B.Sc., M.B. (Cal.),
B.T.M. (Cal. & Liverpool), F.I.C.

Chemical Examiner to the Government of Bengal,
Calcutta

THE medico-legal work carried out by the chemical examiners in India involves examination of large numbers of garments and other articles for the detection of seminal stains. As these cases appear to be steadily increasing in almost all the provinces, a quicker method of examination is very much in demand to-day. The chemical tests for semen are known to give satisfactory results, but there is such a sharp difference of opinion about the significance of these tests that nobody feels inclined to utilize them for purposes of giving a definite verdict in such cases.

The chemical tests for detection of semen depend on the fact that a base, choline, which is found free in seminal fluid, combines with various alkaloidal reagents to form characteristic micro-crystalline compounds. Chemically, choline is trimethyl- β -hydroxy-ethyl-ammonium hydroxide,

that is, ammonium hydroxide in which one hydrogen atom is replaced by the oxyethyl group ($\text{CH}_2\text{CH}_2\text{OH}$) and the other three by methyl groups. It is present in all living cells usually in the form of lecithin which is a compound of choline with glycerophosphoric and fatty acids. The seminal fluid contains as much as 0.514 per cent of choline, mostly as a free base, while brain contains 0.325 per cent (Fletcher *et al.*, 1935) which does not occur, even partially, in the free state (Barger, 1914). In healthy blood it is only 0.031 per cent and that also in the form of lecithin (*loc. cit.*).

Lecithin is present in healthy prostatic secretion in the form of small refractile granules which are known by the name of lecithin bodies.

(Continued from previous page)

These results (which are based mostly on one stool examination from each individual) confirm the conclusions arrived at by Mackie and Chitre. The yeast-like fungi are present in such large numbers of healthy individuals that no significance can be attached to their presence in any particular infection without additional evidence.

Mackie, F. P., and Chitre, G. D. (1928). *Indian Med. Res. Mem.*, No. 11, p. 36. Thacker, Spink and Co., Calcutta.

As prostatic secretion forms an important component of seminal fluid, in the normal course semen contains choline as a free base as well as a compound in the form of lecithin. The amount of lecithin in the prostatic secretion depends on the healthy condition of the prostate—any inflammatory process, whatever be its cause, tends to diminish or stop the secretion of lecithin bodies (Pelouze, 1928). In a person suffering from prostatic troubles, acute or chronic, his semen may be deficient in or free from them. Lipase and certain other ferments act upon lecithin and convert it into choline, glycerophosphoric acid, etc. (Maclean and Maclean, 1927). It is not known if any such ferments are present in the testicular secretion and are responsible for such a large amount of free choline in semen.

Choline and other natural bases are precipitated by alkaloidal reagents, e.g., mercuric chloride, iodine in potassium-iodide solution, platinic chloride, picric acid, phosphotungstic acid, Dragendorff's reagent, tannin, etc. (Barger, 1914). The fact that iodine in potassium-iodide solution precipitates the natural bases completely as periodides forms the basis of the test of Florence who first utilized this property in 1897 for detection of semen, and the choline periodide crystals were described as spermine iodide. Bocarius (1901) first proved that the crystals were of choline periodide. The most delicate precipitants are Stanek's concentrated potassium tri-iodide solution (153 grammes of iodine and 100 grammes of potassium iodide in 200 grammes of water) and solution of mercuric chloride or platinic chloride in absolute alcohol.

The precipitation of choline as a micro-crystalline choline picrate by saturated picric acid solution (alcoholic or aqueous) forms the basis of Barberios' test for semen.

Both the chemical, rather the micro-chemical, tests—Barberios' and Florence's—have been successfully employed in medico-legal work. Barberios' test has not been popular on account of an amorphous precipitate being produced at the same time by picric acid on albuminous substances and of the pleomorphism of the crystals. A preliminary treatment of the stain with 2.5 per cent trichloroacetic acid as introduced by Harrison (1932) has affected the sensitiveness of the test. It takes a much longer time and sometimes fails to develop the crystals in old stains and in stains with scanty material. The facts that picric acid forms crystalline and amorphous compounds with a large number of substances and that the garments received for examination in these cases are likely to contain food-particles, faecal matter and various other extraneous substances render difficult, if not impossible, the identification of various forms of choline picrate crystals (spermine picrate as it was originally called) from other crystalline compounds which may be produced by picric acid with the unknown substances. The following forms of choline picrate crystals are

generally found under the microscope—(1) Lenticular forms looking like Charcot-Leyden crystals, (2) needle-shaped crystals appearing either singly or as crosses and star-shaped, (3) crystals with irregular outline—some of them being H-shaped, and (4) crystals with a feathery appearance.

Florence's test is, on the other hand, quite popular with the medical jurists all over the world. The choline periodide crystals (the probable formula being $C_6H_{14}ONLI_6$ or hexaiodide) are all monoclinic prisms or rhombic plates of a dark-brown colour. They appear mostly as single crystals and some as crosses or in clusters. Sometimes a few fine needle-shaped crystals are also formed along with the prisms. The shape, size and colour of these crystals are so very characteristic that they cannot possibly be mistaken for anything else but the hæmin crystals obtained from hæmoglobin by an altogether different method and with different reagents. This test is undoubtedly a valuable one but there is no unanimity among the workers about its actual value. Some consider that it is a valuable negative test (Taylor, 1934; Thomas, 1937), some are of opinion that it is a useful preliminary test (Smith, 1938; Gonzales, Vance and Helpert, 1937), and there are others who do not seem to take any notice of it and are guided entirely by the presence or absence of spermatozoa. On the other hand there are a few workers who base their opinion mainly on this test.

While examining in this laboratory several thousands of specimens extending over a number of years, it has been observed that in a fairly large number of cases giving negative Florence test, entire spermatozoa are found in the stains (Bagchi, 1937). In an old specimen of a seminal stain, carefully preserved for over six years in this department, spermatozoa are detected quite easily even now but the Florence is always negative. In fresh stains on clothes, if not carefully dried or if mixed with blood or pus, no positive result by the Florence's test is obtained even after 24 hours, while the spermatozoa are detected without any difficulty (Chakraverti and Roy, 1938). These facts prove conclusively that choline of semen is rapidly decomposed, possibly by bacteria, especially in the presence of albuminous substances like blood and pus, into substances which do not give the characteristic micro-crystalline precipitate of periodide, while the spermatozoa being comparatively more resistant escape the action of bacteria and are detected under the microscope. A negative Florence has therefore no medico-legal value. It only proves the absence of choline either as a free base or as a salt, and does not prove the absence of semen in the stain. It indicates on the other hand the necessity for a careful search for spermatozoa under the microscope in a few well-stained slides, before a definite negative verdict is pronounced. It may also be noted

that choline, if esterified, does not give a positive reaction (Booth, 1935).

How choline disappears from the stain is not properly understood. It has been found that certain bacteria present in hay-infusion convert choline into another base known as neurine ($C_6H_{13}NO$) while *Bact. prodigiosum* decomposes it completely into trimethylamine (Barger, 1914). The organisms of the proteus group are also believed to produce disintegration of the natural bases along with the protein constituents. An investigation as to the stability of choline in seminal fluid is in progress.

The next point for consideration is the value of a positive Florence reaction. Most of the workers in this line hesitate to give a definite opinion on the basis of a positive test, and consider it as a presumptive test to be confirmed by microscopic examination of the specimen. The hesitation or the disinclination to take the positive result as the final test originates from the belief that choline is present in almost all animal and vegetable tissues, and therefore a positive result may be given by these extraneous substances if they happen to be present in the articles under examination. Since choline is a constituent of lecithin it may be found in blood and other tissues, but there is no possibility of its presence as free choline and in sufficient quantity to be detected by the Florence reagent. Semen is the only biological material in which choline is found free in large quantity, and this is the reason why a minute trace of semen sticking to hair or fine cotton fibres gives well-marked crystals under the microscope. The animal or vegetable tissues containing combined choline require tediously long processes for liberation and extraction of this base in sufficient amount for detection by any of the delicate reagents stated above. Even pure lecithin which is rich in choline does not give a positive reaction with the Florence or any other delicate reagent, but if hydrolysed by boiling with saturated baryta solution or 40 per cent sulphuric acid (Barger, 1914) it splits off choline and gives a positive result. If a suspension of pure lecithin (egg lecithin of Schering-Kahlbaum) in water is kept overnight at room temperature slight spontaneous hydrolysis takes place and choline is liberated, but the yolk of egg under the same condition does not undergo any hydrolysis. It is true that bacterial action, specially during putrefaction, liberates choline from lecithin of the tissues, but the amount obtainable from a small quantity of any of the tissues, except perhaps brain and spinal cord which cannot possibly by any stretch of imagination be connected with a suspected seminal stain in a garment, is negligible for purposes of the Florence test. Besides, the action of putrefying bacteria does not end in simply liberating choline, but proceeds further until the base itself and other products of putrefaction are decomposed into monoethylamine, triethylamine and

other simpler compounds, and finally into CO_2 , NH_3 , CH_4 , etc.

To demonstrate the possibility, or otherwise, of actual liberation of free choline or any other base of that type in various substances, which may be present as contaminations in garments received for medico-legal examination, the following materials were examined:—Blood from finger tip; heart blood; menstrual blood; leucorrhoeal discharge of adult females and young girls of both specific and non-specific origin; normal vaginal secretion; pus from suppurated Bartholin's gland; pus from boils and gonorrhoeal urethritis of men and women; nasal discharges; sputum; human faeces; cow dung; starch solution; white and yolk of eggs and fruit juices. In fact all sorts of materials which might be found on the clothes of men or women involved in cases of sexual offences were examined and not a single one of them gave even a doubtful positive reaction. To imitate, as far as possible, the actual condition of ordinary seminal stains, the materials were applied to clean linen and also to pieces of cloth snipped off from dirty garments received in connection with rape cases. The artificial stains, thus produced, were examined exactly in the same way as the actual stains are examined in our routine work. In addition to those, ox bile and some brain tissues from man and sheep were also submitted to the same method of examination to see if these substances, rich in choline, could give a positive reaction, but the result was the same throughout. Some of these stains were tested every alternate day for about two weeks, but the bacteria present in air, water or the dirty clothes on which the stains were prepared did not produce any effect on the choline-containing substances.

The results of these experiments should impress upon the workers in this line the necessity of revising the existing notions about this test. There is absolutely no possibility of a positive reaction from sources other than the seminal fluid and consequently there should not be any hesitation on the part of the medical jurists to pronounce a positive verdict on the basis of a positive Florence test, which obviously admits of no fallacies to vitiate the result.

Another important observation, which may lend additional weight to the conclusion already arrived at, may now be considered. Under certain conditions, the semen of healthy persons shows no spermatozoa at all (aspermia) or at most a few spermatozoa (oligospermia) under the microscope. These cases are not so rare as we usually believe. Lately, an investigation has been taken up by the medical officers in charge of the Hospital for Women, Leeds, to determine the causes of infertility of men (Currie and Lissimore, 1939). Out of 166 samples of semen obtained from sexually potent husbands, they found 18 per cent to be aspermic and 38 per cent oligospermic. In this country no such investigation is yet possible, but I believe the possibility

of finding such cases among men who are involved in sexual offences is not so remote as to dismiss the question without going through it carefully. I had occasion to examine fresh specimens of semen of about half a dozen aspermia cases and in every case, except one who had other abnormalities as well and gave a doubtful reaction, the Florence test was strongly positive. If the presence of spermatozoa is considered as the only criterion for giving a positive diagnosis, the examiner is obviously on the wrong tack and his opinion will be extremely fallacious if he ignores in such a case the positive Florence test and depends on the result of search for spermatozoa. A positive Florence test may therefore be safely taken as an indication of the presence of seminal fluid.

Summary

Seminal fluid is the only biological material which contains a very large amount of free choline which gives the characteristic choline periodide reaction known as the Florence test. Choline when not free, for instance in lecithin, does not produce the reaction.

A negative Florence test has no medico-legal value; known seminal stains, under certain conditions, give a negative Florence reaction while entire spermatozoa are easily found under the microscope.

A positive Florence test is important and indicates the presence of semen. Various animal and vegetable matters which are likely to be present, as dirt or contaminations, in the garments of men or women involved in sexual offences, were examined for choline by the periodide test, but the results were negative in every case. There is no possibility of a false positive.

Cases of aspermia are not rare—the seminal fluid of these men gives a strongly positive Florence reaction, although it does not contain any spermatozoa. As these men are sexually potent, the presence of spermatozoa should not be the only criterion for giving a positive diagnosis. A positive Florence test therefore may be taken as an indication of the presence of semen.

A Mirror of Hospital Practice

URTICARIA FOLLOWING LIVER EXTRACT

By RAMANIK H. DESAI, L.C.P.S. (Bom.), L.T.M. (Cal.)
Honorary Medical Superintendent, S. M. Maternity Home, Santh Pipli, Nadiad

A FEMALE patient, aged 27 years, was given an injection of Campolon 2 c.cm. Immediately afterwards there was irritation near the site of injection, and a few weals appeared. She was also restless.

Next time she was injected with another brand of liver extract and the result was the same. 'Exatrope' was used on the third occasion, and she had a very severe reaction. Weals appeared after a few minutes all over the body, accompanied by irritation and restlessness. On the fourth occasion 5 c.cm. of Campolon preceded by a dose of ephedrin $\frac{1}{2}$ gr. was given and the reaction was less severe.

The woman was very anæmic. The red corpuscles were below 1 million per c.mm.; her leucocyte count was normal. Hæmoglobin was 65 per cent.

Previous history.—She was delivered of a female child on 11th January, 1939, and she developed *B. coli* infection on the 13th day of the puerperium. Also she had diarrhoea, colic and sore mouth. Stools showed only cellular exudate and the urine was normal. She had an irregular temperature varying between 102 and 104°F. Her pulse was 130.

I persisted with Campolon injections because I considered liver extract given orally would not have been of much use on account of her gastro-intestinal condition, and she improved very much.

Can liver extract be given intravenously and with safety in such cases?

[Note.—The answer is that it is not safe to give ordinary liver extract intravenously in any case and much less to an obviously sensitive patient.

For intravenous administration special protein-free liver extracts are prepared. It might be safe to give one of these in such a case.—EDITOR, I. M. G.]

M. & B. 693 IN PNEUMONIA

By W. J. MODY, M.A., M.B., F.R.C.S. (Edin.)

CAPTAIN, I.M.S.

British Legation, Kabul

PNEUMONIA is a much dreaded disease among the European and Indian communities of Afghanistan on account of the extreme severity of the winter. For three or four months the daily minimum temperature in Kabul falls to between 20 to 30 degrees below freezing point. Generally in the winter a few cases of pneumonia occur among the legation staff.

Although our incidence is trifling and the results correspondingly insignificant in comparison with world statistics, it may be of interest to quote our experience as adding a 'widow's mite' to the weight of evidence in favour of M. & B. 693.

In the winter of 1937-38 there were two cases of pneumonia both of which proved fatal. During the past winter (1938-39), there were three cases with no deaths. The first of these was treated non-specifically, and recovered following a crisis on the fifth day. The other two (described below) were treated with M. & B. 693, and the results were as dramatic as they were satisfactory.

Case 1.—A. H., a cook, aged 45 years, was admitted on 1st February, 1939, having become ill the previous day with fever, cough, and pain in the left chest. He stated that he had suffered from chronic bronchitis and a 'bad heart' for over two years. His temperature was 101.6°F., his pulse 118, irregular and respiration 38 per minute, there was a double murmur at the apex. There were scattered râles over both lungs, with crepitations and signs of commencing consolidation over the left base. He was given M. & B. 693, 2 tablets 4 hourly for 36 hours, followed by 1 tablet 4 hourly for 48 hours, and then 1 tablet t.d.s. for a further 48 hours. Within 24 hours of commencing treatment his temperature fell to 97.4°F. and remained subnormal until the 6th day when it rose to normal and remained so until his discharge on 8th February. During the last two days of administration of the drug he complained of slight abdominal discomfort and nausea; he never actually vomited.

Case 2.—M. Y., a car cleaner, aged 40 years, with two days' history and definite signs of consolidation over the left lower lobe. Temperature 101.5°F. Pulse 102. Respiration 33 per minute. He also was given M. & B. 693, dosage as for case 1, and with the same result. The temperature fell to subnormal within 24 hours, and remained so until his discharge from hospital. He displayed no untoward effects from the treatment.

Chand, Taylor and Chitkara point out that there are no obvious signs of resolution occurring 'in an abnormal way or at an earlier or later period than usual'. This is what one would expect as the drug merely arrests the infective process. Presumably repair of the damaged lung tissue is carried out by the body by its normal processes.

Dutta stresses the importance of 'good nursing'. With this, and all that the term implies, everyone will be in the fullest agreement, and furthermore I am sure that the need for it remains as essential as ever even though we have at our disposal such an effective drug as M. & B. 693.

NOVEMBER

IRON METABOLISM

IRON is an essential element in mammalian dietary. A certain minimal amount is required by the cells of the tissues for maintaining normal metabolism, and, however much an animal is starved of iron, this small amount of iron is held by the tissues. The main needs of the body for iron are for the formation of hæmoglobin. Blood destruction and blood formation are continuous physiological processes and in an average-sized man obsolete red cells equivalent to about 200 c.cm. of blood are destroyed and replaced daily. The amount of iron required for this blood formation is considerable, but fortunately the body is capable of re-utilizing the iron from the destroyed corpuscles; further, the tissues of the body, particularly those of the liver, have a great capacity for storing iron, so that temporary deficiencies of iron are easily compensated.

In the processes of blood destruction and blood formation, there is a considerable wastage of iron and this wastage has to be made up. The wastage is met by iron in the food. The amount of iron required daily is variously estimated as 10 to 15 mgm. Most food substances contain iron, some in larger amounts than others, and in nearly all food tables the iron content of each substance is given, so that by tabulating the substances taken by an individual and looking up the iron content it should be an easy matter to calculate whether that individual is taking enough iron.

It is not, however, as simple as this. Iron taken in the food is not assimilated quantitatively. As is the case with medicinal iron, from some food substances a large percentage of the iron is absorbed and utilized, and from others little or none. This has been appreciated for some time, and a few years ago Hill devised a method for estimating the inorganic iron in food by means of dipyriddy. The method has since been elaborated, adopted as a means of testing the 'availability' of iron, and applied extensively; and in many books on dietary, tables showing the percentage 'availability' of the iron in different food substances are given. For example, there is such a table in the *Health Bulletin No. 23* (1st Edition), which shows that the percentage availability of iron varies from 19 in spinach to 90 in the tinned peas, being 47 per cent in wheat, and 70 per cent in beef (heart or liver).

Thus, we appeared to be progressing towards a more accurate appraisal of the iron value of food substances, though the discrepancies in the findings of different workers were causing some uneasiness; for example, in spinach, to which we

have already referred, the availability of the iron is given as 19, 25, and 68 per cent by different workers. Now, however, our hopes in this direction have been entirely shattered by the work of Whipple and others who have shown that there is little parallelism between the dipyriddy value and the true availability of iron tested by animal experiment. For practical purposes we are now where we were ten years ago. The biological test appears to be the only one that can be trusted and it will be many years before the figures for all common food substances will be available, especially as a further complication has been added by the fact that from any one substance the iron is not absorbed quantitatively, as it was shown in some experiments that the larger the amount given the less was the percentage absorbed.

Dr. Aykroyd, appreciating the present position, takes the view that in the present state of our knowledge the only safe procedure is to allow a good margin of safety and in the new edition of *Health Bulletin No. 23* he suggests that for a mixed diet 20 mgm. of iron a day should be sufficient to meet all normal physiological calls, and we note that he has omitted the iron-availability table. Dr. Aykroyd's and the Coonoor Nutritional Research Laboratories point of view are expressed in a recent paper (*I. J. M. R.*, 26, 119) by Dr. Ranganathan.

The ryot in India lives on a diet which is almost certainly very close to the iron-deficiency line. Rice is poor in iron, particularly when it is milled, so that 'on paper' most of his iron is derived from pulses, vegetables, fruits, or meat. The iron derived from vegetables is on the whole of low availability, whereas that from meat is on the whole high—it is not safe to be more precise than that—so that the ryot whose food consists mainly of rice and who takes no meat is probably living on a diet deficient in iron.

If to this state of affairs a blood loss is added, as for example in hookworm infection, he will certainly suffer from an iron-deficiency anaemia.

In an investigation on the anaemia in coolies in Assam, Napier (*I. M. G.*, 72, 270) and his co-workers found that in 39 out of 41 unselected anæmic coolies the anaemia was of the hypochromic microcytic type and that in every case there was a marked improvement in the blood picture when iron was given in large doses. All these coolies had a hookworm infection, but this varied in degree. It is only possible to conclude, firstly, that these patients were suffering from an iron-deficiency anaemia, and, secondly, either that the available iron they were receiving in their diet was insufficient for their particular requirements, or that for some reason they were not absorbing it; the latter alternative, though it was considered, was ruled out for various reasons including the fact that they absorbed it readily when it was given in medicinal form. Admittedly, in these coolies their requirements were not the normal physiological requirements of iron, but added to this was the requirement

for additional iron to replace the iron lost in the blood that was continuously being removed by hookworms.

Elsewhere in this number will be found a paper by Dr. Mitra who has carried out a dietary survey amongst the same population in which these cases of hypochromic microcytic anæmia were found. He has shown that whilst the average iron intake in two groups investigated was 18.77 and 27.79 mgm., respectively, the average of the 'available iron' was only 4.61 and 6.73 mgm.: further, of 72 families in which dietary surveys were done, in only one was the 'available iron' up to 12 mgm. which Dr. Mitra, accepting Sherman's standard, considers to be the minimum requirement. Thus, on the one hand, according to the *Health Bulletin* standard of 20 mgm., the two groups as a whole and the majority of the individual families appear to be receiving sufficient iron, but, on the other hand, when the availability of the iron is taken into consideration their diet is shown to be grossly deficient in this element. It is obvious that these opposing points of view cannot be composed until we have much more accurate data on the true availability of iron in different food-stuffs. Even if they were in agreement we

should still be no nearer the fact which we want to ascertain, namely, the *particular iron requirements* of this hookworm-infected population.

There are in the estimation of iron in food on the one hand and on the requirements of the individual on the other, so many variables, that chemical methods of estimating iron balance are of doubtful value, and one is inevitably thrown back on to the clinical, or biological, method; in our opinion far more importance should be attached to the demonstration, by the combined hæmatological and therapeutic methods, of iron deficiency in the population concerned than by any dietary survey. The blood picture of iron-deficiency anæmia, a microcytic hypochromic anæmia with a very low mean corpuscular hæmoglobin concentration, is characteristic and the typical response with a sharp reticulocyte crisis to the administration of ferrous iron in large doses puts the diagnosis beyond question.

When, however, the dietary survey points to the same fact, as in this case, this may be accepted as contributory evidence that the people are living on a low iron intake and are therefore in a low state of iron balance which is easily turned into a deficit by the extra drain of blood lost through a hookworm infection.

TROPICAL SPRUE

A RESUME OF A LECTURE

By L. EVERARD NAPIER, M.R.C.P. (Lond.)

Professor of Tropical Medicine, School of Tropical Medicine, Calcutta

Definition.—A diarrhoeal condition of uncertain ætiology characterized by the passage of large, light-coloured and frothy stools, usually in the morning, flatulent dyspepsia, and sore tongue, and in its final stages a marked macrocytic anæmia, occurring amongst people who live, or have lived, in certain tropical countries.

EPIDEMIOLOGY

Geographical distribution.—China, India, Ceylon, Malaya, East and West Indies, South U.S.A., Central and South America, South Italy, and Queensland; that is to say, it is mainly tropical, but a few subtropical areas are included and the disease is rare in tropical Africa.

Age and sex.—It shows a female predominance and is most common in middle age, but it may occur in young people and even in children.

Race.—Mainly Europeans, particularly domiciled Europeans, and Anglo-Indians, but typical sprue also occurs in Indians, and other indigenous inhabitants.

Climate.—It occurs in hot damp coastal climates. It is regional as well as climatic; that

is to say, sprue is often common in one and rare in another of two places that appear to be climatically identical. It often follows long or frequent hill residence and repeated attacks of hill diarrhoea.

Seasonal.—The onset is usually after or during the rains.

Other epidemiological observations.—Sprue houses have been reported and this has led to theories regarding its infectious nature; and some people have associated it with ants, and with dry rot. Husband and wife not infrequently both suffer from the disease.

Ætiology.—There are numerous theories regarding the ætiology of this disease:—

(a) *The infective theory.*—There are still a large number of writers who consider that the evidence is in favour of some infective organism being the cause of the disease; the points in favour of this are the tropical and regional distribution, the fact that husband and wife and sometimes whole families are infected, and that 'sprue houses' have been reported. The organisms under suspicion can be grouped as follows:—

(i) *Monilia*, especially *Monilia psilosis*, or *Parasaccharomyces ashfordi*. This theory was supported by Ashford, Manson-Bahr, and Kohlbrüge, but it is now generally considered that their presence is simply a matter of the suitability of the bowel contents in sprue as a

medium for these organisms. It has been shown that this and other monilias are present in the bowel under normal conditions, and that in any diarrhoeal condition they may become more abundant.

(ii) Streptococcal infections. Haemolytic streptococci are usually obtainable from the stool and mouth, but are probably secondary invaders.

(iii) Some specific organism as yet unidentified.

(b) *Calcium deficiency.*—The total calcium is below normal in about half the cases, but the more marked deviation from normal is the reduction in ionic calcium, which was at one time thought to be due to dysfunction of the parathyroids, possibly caused by excessive strain on its detoxicating functional activity; it is now thought that it is due to failure of absorption.

(c) *Simple failure of absorption due to degenerative and atrophic changes in the intestinal mucosa.*—Recent work has shown that there are no constant histological changes in the mucosa of the gut in sprue.

(d) *Food deficiency.*—Absence or deficiency of A and B vitamins, extrinsic factor deficiency, and deficiency of certain important amino-acids, have all been suggested.

(e) Finally, Fairley has suggested that it is a metabolic failure, a functional rather than a mechanical failure to absorb and to utilize both fats and carbohydrates.

All these theories can to a certain extent be correlated, and in the writer's opinion sprue is a metabolic breakdown, a failure to absorb and utilize fats, glucose, calcium, haemopoietin, and other essential substances, as a result of some infection, or a succession of debilitating infections (exhaustion of the parathyroid), unsuitable diet over a long period, including excess of carbohydrates and fat with deficiency of good protein, and an ill-distribution of blood supply in a hot and humid climate, in which the skin demands too much blood and the viscera are left in a relatively anæmic state.

Pathology.—Changes from mouth to ileo-cæcal valve have been described. Thinning and loss of papillæ of mucous membrane of the tongue which is easily damaged and therefore there are aphthous ulcers and general soreness, loss of submucous tissue and atrophy of the muscles. There are no constant changes in the mucous membrane in any part of the intestinal tract, but thinning of the mucous membrane, loss of submucous tissue, and wasting of muscular coats; any ulceration that occurs is incidental and on part of the general pathological picture.

The previous misconceptions regarding the pathology of sprue are thought to be due to post-mortem distension and rapid degenerative changes. This can be obviated by rapidly injecting formalin into the intestinal tract immediately the patient dies; if this is done no histological changes will be seen in the mucous membrane.

Heart.—Small, brown atrophy. *Liver and spleen*—small, loss of 20 to 30 per cent in weight—prussian blue reaction.

Kidneys.—These show similar changes.

Bone marrow.—There is a general megaloblastic hyperplasia, with a peculiar gelatinous appearance of the marrow, which is found in certain nutritional anæmias and is probably due to specific starvation. Suprarenal atrophy and degeneration in the pancreas are described.

Blood.—There is a decrease in fat—to 0.4 g. (normal=0.6 g.) per 100 c.c.m., and in the ionic calcium which is usually about 7 to 9 mg. Cholesterol is reduced to 70 mgm. (normal=150 to 200) and even down to 40 mgm. The glucose curve after ingestion tends to be flat, whereas after intravenous glucose it rises sharply, but does not fall as quickly as normal; general carbohydrate starvation has produced hypo-activity of endogenous-insulin.

The van den Bergh (indirect) is usually slightly above normal and the urobilin in the urine is increased.

There is usually a macrocytic anæmia with normoblasts but rarely megaloblasts in peripheral blood.

Gastric analysis.—Free acid is usually present but the acid curve is low. Mackie and Fairley found achlorhydria in 14 of 44 cases.

Stools.—The first stool in the morning is always bulky, pale and frothy; for the rest of the day the stools are pale and fluid, but occasionally normal in appearance. The white appearance is not due to absence of urobilinogen, but to its change to leucobilin by the action of intestinal bacteria.

Normally, the total fat is 10 to 25 per cent of the weight of the dry stool; of this two-thirds is split fat; this split fat is found in the stool as fatty acid or combined as soapy fat. One-third remains as neutral fat.

In sprue, in 80 per cent of cases the fat is over 25 per cent and it may be 60 per cent; two-thirds of this is split, but even more may be split, so that neutral fat to split fat may be 1 to 3 or even 5. The important point is that, though the pancreas is doing its work, the fat is not being absorbed and utilized.

SYMPTOMATOLOGY

The prelude to sprue.—Many patients give a history of an attack of dysentery which is followed by troublesome diarrhoea, for which they have received a variety of treatments with correspondingly varied results. Amongst these treatments is always included a long period of restricted dietary.

Onset.—This may be slow and mild, or mild but insidiously progressive, or rapid and severe. The patient has a sallow muddy complexion, and a parchment-like skin with patchy pigmentation on different parts of the body, e.g., the malar eminences, forehead, buttocks, etc., the nails are brittle and the patient is emaciated and anæmic. The anæmia may be very

prominent and many of the symptoms may be attributable to this. A low irregular fever is not uncommon.

Mouth.—The tongue has a characteristic appearance; at first it is red and sore, the mucous membrane is thickened and folded, then later it is red and smooth with loss of papillæ, and aphthous ulcers form on the frenum and edge of the tongue and in the mouth generally.

Abdomen.—There is the characteristic tumid lower segment, with the thin abdominal wall distended and drum-like in appearance; peristaltic movements are visible, there are borborygmi, and the liver dullness is diminished; this is due to an actual decrease and to the general distension of the intestines.

There is usually œdema of the legs, and loss of knee jerks.

Symptoms.—There is soreness of the mouth and dysphagia particularly for hot food or spices, indigestion and meteorism but seldom vomiting. There is morning diarrhœa, large frothy and bulky stools constantly, with occasional attacks of loose stools throughout the day, but the stools after the first may be formed, general lassitude and weakness, tetany, cramps, and muscular twitchings, and paræsthesias.

There is both mental and bodily irritability, and often neurasthenia.

The appetite is usually poor, but occasionally it is ravenous with disastrous results.

Radiological findings.—The bowel empties rapidly; the colon is reached in 3 hours, and the small intestine empties in 6 hours. The large intestine usually empties rapidly, but there may be obstinate stasis.

Progress.—The condition progresses steadily if rigorous treatment is not undertaken. With half-hearted treatment there may be periods of remission, but eventually symptoms will recur and the disease progress. Death is due to exhaustion and intercurrent disease.

Latency.—The condition may improve and remain latent for some time and then relapse after 1 or 2 years, but sometimes after a longer period.

Incomplete sprue.—Sometimes one particular set of symptoms predominates; gastric and mouth symptoms may be encountered without any diarrhœa, or there may be lower-bowel symptoms without the sore tongue.

Diagnosis.—This mainly depends on clinical observation, but it can be confirmed by chemical examination of the stools and, later, by the development of macrocytic anæmia in the presence of normal or low gastric acidity.

DIFFERENTIAL DIAGNOSIS

Celiac disease.—This is a disease of calcium metabolic dysfunction, not uncommon in children who have been born in the tropics, but it is usually considered to be a congenital deficiency. A similar disease in adults occurring in temperate climates is very like sprue.

Pancreatitis.—Pancreatic dysfunction, due to pancreatitis or new growth, is distinguished by the high percentage of neutral fat in the stools.

Pellagra.—The tongue condition is suggestive of pellagra but the characteristic fatty stools are not found in this disease: the epidemiologies of the two diseases are very distinct.

Other conditions with which it might be confused are *dysentery* and *chronic diarrhœa*, *lambliasis* on account of the fatty stools, and *tropical macrocytic anæmia*. There is some reason to believe that the nutritional macrocytic anæmia that occurs in some countries has been described as sprue.

TREATMENT

There is no short cut to treatment of this condition. The patient must be warned that his whole-hearted co-operation is essential and that he must be prepared to face a period of at least two months of hospital, or the equivalent, treatment.

The treatment consists of rest in bed, a strict dietary régime, and treatment for the anæmia; otherwise it is symptomatic. In cases of macrocytic anæmia parenteral liver extract, hepatex, anahæmin, pernæmon or other well-known preparations, should be given in full doses. This will often produce an immediate improvement in the blood picture. In view of the fact that many patients have been living on a restricted diet, iron should also be given. Even in the cases in which anæmia is most prominent this treatment alone is not sufficient and a dietary régime will be necessary. The reported cases in which liver treatment alone was effective were probably not true sprue, but nutritional macrocytic anæmia.

Diet.—Milk is usually the most suitable diet for Indians. At first milk from which the excess of cream has been removed by skimming, not by mechanical separation, should be given. Commence with 2 pints and increase the amount gradually up to 5 pints or even more daily; give 2-hourly in 4 to 10 oz. feeds; the patient should sip the milk or take it with a spoon. Some patients may have to have butter-milk or peptonized milk at first. Benger's or Horlick's food can be given for variety. Bovril added to the milk will make a change, for those to whom it is not taboo. Later, whole milk should be given, at first in a few feeds and eventually at every feed. Raw egg should also be added. Marmite and fruit juice should be given throughout; later other fruits may be added. *This diet should be continued for at least six weeks.* Advances in dietary should only be made if the patient is symptom-free and, if the symptoms recur, the dietary régime must be started from the beginning and advanced again slowly. For dyspepsia give pancreatic emulsion (Savory and Moore), or takadiastase.

Fruit.—This will depend on the country and other circumstances. Strawberries are favoured in England, but apples, bacl, quince, papaya, or bananas can be given in this country. They

should of course be given finely mashed up in the form of a 'fool'.

Sprulac.—This is a milk substance especially prepared, at the instance of Dr. Hamilton Fairley, for sprue patients: it contains the three food principles protein, fat, and carbohydrate in the proportions, P : F : C=1.0 : 0.3 : 1.3. This is a useful substance when fresh milk is difficult to get or is unsatisfactory, but some physicians, and also some patients, prefer it even when fresh milk is available.

It is issued in the form of a powder to which water is added. The dry powder provides 125 calories per ounce: 5 ounces of dry powder suitably diluted with about 8 parts of water, should form the first daily allowance and this should be worked up gradually to about 16 ounces.

Sprulac should be considered only a substitute for the milk part of the above diet.

Fairley's high protein diet.—This diet, which is designed to maintain the high protein ratio, P : F : C=1.0 : 0.3 : 1.3, in place of the normal 1.0 : 1.0 : 5.0, is suitable only in western countries or in large towns where a good meat supply is available.

There are five dietary stages, each of which should be maintained for 1 to 2 weeks or even longer according to the severity of the case.

The main meals are given at 8 a.m., noon, and 7 p.m., but if the patient is very weak they can be divided. As more substances are added, tea is given at 4 p.m., then at 6 a.m. as well, and a mid-morning meal at 10 a.m. is put in. The details of this high-protein diet are reproduced in books on tropical medicine; a summary is given in tabular form below:—

Scott's treatment with calcium lactate gr. xv *t.d.s.* and parathyroid 1/10 gr. *b.d.*, combined with milk diet, has had a number of advocates.

Vaccines have also had their day; Rogers and Knowles claimed good results with streptococcal vaccines, and monilia vaccines have been advocated by the adherents of the monilia theory of the aetiology. Any good effect of vaccines is probably a non-specific action.

The introduction of the sulphanilamide group of drugs has provided another means of attacking the secondary streptococcal infections of the bowel in sprue, and good results have been obtained by the administration of sulphonamide, for example.

The value of liver in this disease was recognized long before the introduction of liver therapy in pernicious anaemia; liver by mouth and perhaps even more so by injection, on account of the defective absorption from the intestinal canal, has a remarkable effect on both the blood picture and the general condition of the patient, but, as we have already said, it is not a specific and dietetic treatment is usually necessary as well.

MEDICINAL AND GENERAL TREATMENT

A purgative may be given at the commencement of treatment, a full dose of castor oil, or pulv. rhei co. If there is any tendency to constipation liquid paraffin, petrolagar, agarol, or one of the *Plantago ovata* group, in the form of *ishabghul*, obtainable in the bazaar in India, normocol or isogel should be given regularly. The atonic condition of the bowel may have led to a constipated condition where

TABLE

Stage	Calories	AT EACH OF THREE MEALS				Additional; at one meal, unless otherwise stated
		Underdone beef, oz.	Rusks, oz.	Glucose, drachms	Oranges (juice)	
1st	770	3	1	2	1	4 oz. soup + ½ lb. liver extract.
2nd	1,280	5	1	2	1	Ditto + 2 oz. calves-foot jelly at two meals + tea with 2 oz. milk.
3rd	1,820	6	1½	2	1	Ditto, ditto + baked apple and 1 oz. custard twice, with tea twice, and calves-foot jelly three times.
4th	2,200	7	1½	3	1	Ditto, ditto, ditto, with soup now 5 oz. and custard 3 oz. and double ration of rusk at one meal.
5th	3,020	7	3	4	1	Ditto, ditto, ditto, ditto + 2 drachms butter, scraped or mashed fruit + 2 drachms honey at two meals, boiled or poached egg.

Specific treatments.—It has been said that there are 365 infallible cures for sprue, which of course means that there is no specific for this disease. A few of the treatments that have been successful in special cases should be mentioned.

there are large faecaliths in the bowel that may necessitate warm oil enemas for their removal.

It is probably not advisable to interfere too much with the *diarrhoea* if it occurs in the early stage before treatment has had time to take

'NEUROPOIETIN PRINCIPLE IN GASTRIC SECRETION'

THE ÆTIOLOGY OF CENTRAL NERVOUS SYMPTOMS IN PERNICIOUS ANÆMIA

By A. N. SHAHA

Bombay

THE extremely common occurrence of symptoms referable to the central nervous system in pernicious anæmia has led most authors to the conclusion that it is a part of the same disease process. It is believed by some that the manifestations in the spinal cord in pernicious anæmia may result from a vitamin deficiency. Others still maintain that there is a specific neurotoxin due to a disturbance in lipid metabolism, or the changes in the central nervous system are related directly to the anæmia.

Recent observations appear to demonstrate the nature of the physiologic defects in pernicious anæmia leading to a deficiency of liver extract—hæmopoietin principle. Failure of the formation of blood in persons with pernicious anæmia has been demonstrated to be due to the absence of a specific reaction, which in the normal person takes place as a result of the presence in the stomach of a specific factor in the food (extrinsic) and a factor in the gastric juice (intrinsic) (Castle, 1929; Castle *et al.*, 1931).

In pernicious anæmia, disturbances of the gastro-intestinal tract and of the central nervous system are associated. Neural (Smithburn and Zervas, 1931; Goldhamer *et al.*, 1934; Baker *et al.*, 1932; Strauss *et al.*, 1935) and sometimes mental symptoms (Lurie, 1919; McAlpine, 1929)

(Continued from previous page)

effect, but later if the diarrhoea is troublesome or disturbs the patient at night kaolin or bismuth and heavy magnesium carbonate should be given.

For *flatulence* and *indigestion*, a mixture of sp. ætheris nitrosi and sp. ammoniæ aromaticus 15 min. of each in half an ounce of peppermint water should be tried first, but if the indigestion persists, in view of the low acidity, an alkaline mixture should be given before meals and dilute hydrochloric acid, half to one drachm, after meals.

For *meteorism* turpentine in minim doses, turpentine stupes, and finally pituitary extract should be given.

Nursing.—Careful nursing will of course form an important part of the treatment and special care should be directed towards the mouth. A potassium chlorate mouth wash, a drachm to the pint, should be used, or if the mouth is painful glycerine and borax, with 2 grains of cocaine to the ounce in extreme cases when the soreness is interfering with the taking of nourishment.

may appear long before the development of pernicious anæmia (Greenfield and O'Flynn, 1933). Ahrens (1932) has stated that early cases of pernicious anæmia would probably at some time show evidence of sub-acute combined degeneration of the cord. The neurological signs (Wood, 1925; Baumgartner and Smith, 1927; Hance, 1930) and degenerative changes in the spinal cord (Reed and Wyckoff, 1926), in cases of pellagra and in sprue resembling those in pernicious anæmia, have been observed. The gastric atrophy and secretory failure classical in pernicious anæmia occur also less frequently in pellagra (Denton, 1928; Lynch, 1930), and in sprue (MacKie and Fairley, 1929; Castle *et al.*, 1935). The observations of Minot and Murphy (1927), Cohn and his associates (1928), Ungley and Suzman (1929), Strauss and Castle (1932) and of others on liver therapy in pernicious anæmia demonstrated an improvement of the anæmia and of the symptoms in the spinal cord. The results of the investigations possibly may lead to the discovery of a physiological principle other than hæmopoietin, which might be involved in the ætiology of central nervous symptoms in pernicious anæmia. Ungley (1931) has suggested that the nervous lesion is due to the lack of some factor other than the effective principle in liver.

The neuropoietin principle is identical with the hæmopoietin principle; in pernicious anæmia both these factors are absent. Salus and Reimann (1934) found that Castle's intrinsic factor was present in five cases with the typical picture of sub-acute combined degeneration of the cord with achylia but a normal hæmatologic picture was observed. They determined the presence of intrinsic factor by reinforcing liver therapy with gastric juice obtained from these patients and feeding it to patients known to have pernicious anæmia. They further determined that Castle's intrinsic factor was not present in seven cases in which sub-acute combined degeneration, achylia and the hæmatological picture of pernicious anæmia were observed. In nine cases with sub-acute combined degeneration of the cord, reported by Russell and his associates (1900), no anæmia was recognized throughout the disease, in others it developed towards the end, while in others it preceded the manifestation of nervous symptoms by many months. They stated that repeated examinations of the blood failed to reveal the alterations found in pernicious anæmia, the changes being those characteristic of secondary anæmia. Schaeffer and Vialard (1929) reported a case in which anæmia was said to be absent and diarrhoea was present; the disease resembled the sub-acute combined degeneration of pernicious anæmia. A case of sub-acute combined degeneration has been reported, in which achylia was present (Thomas *et al.*, 1929). The pathological changes in the stomach of patients with sub-acute combined degeneration are not different from those with Addison's

pernicious anaemia without neurological phenomena (Magnus and Ungley, 1938).

Williams (1914) has stated that besides the familiar gross lesions in the peripheral nerves and spinal cord, pernicious anaemia may give rise to alteration in the brain cells to produce mental symptoms. Warburg and Jorgensen (1929) have stated that there is a chronic pathological condition associated with achylia gastrica which covers a great many cases of neurasthenia and some cases of early psychosis, and that these mental disorders are often associated with mild spinal symptoms, glossitis and megalocytic anaemia. It has been suggested that pituitary deficiency may be followed by achlorhydria, which may induce after a long interval an iron-deficiency anaemia, a liver-deficiency anaemia, cord changes or a combination of these conditions (Snapper, 1937; Snapper *et al.*, 1937).

The occurrence of nervous changes in pernicious anaemia was first noted by Addison in his classical description. Recently, several authors have noted the frequent occurrence of neural changes in cases with pernicious anaemia, noting their presence in over 60 per cent (Smith, 1929; Piney, 1932). Some authors have reported the occurrence of involvement of the spinal cord in 90 per cent or more (Smithburn and Zervas, 1931; Goldhamer *et al.*, 1934; Strauss *et al.*, 1935). According to others (Smithburn and Zervas, 1931; Schilling, 1931; Young, 1932) neural symptoms in pernicious anaemia may develop in 80 to 100 per cent. Woltmann (1919) found that of 150 cases with pernicious anaemia 80.6 per cent presented evidence of the nervous involvement. This was confirmed by Hennerberg (1924) and by Meulengracht (1926).

Cole (1924) in an analysis of 21 cases of pernicious anaemia found lesions in the central nervous system in 87 per cent. Riggs (1924) stated that the nervous disturbances in pernicious anaemia may be observed in over 80 per cent of the cases. This has been confirmed also by the others (Reese and Beigler, 1926). The majority of the investigators are of the opinion that more than 80 per cent of the cases with pernicious anaemia exhibit neurologic manifestations (Baker *et al.*, 1932; Ungley and Suzman, 1929; Grinker, 1926).

Hurst (1934) has stated that the production of the hæmopoietin and neuropoietin substances are very rarely diminished sufficiently to give rise to Addison's pernicious anaemia and sub-acute combined degeneration of the cord, except in very severe cases of gastritis in which true achylia occurs. When gastritis is so severe as to cause complete destruction of the oxyntic cells, it may also destroy the cells which produce hæmopoietin and neuropoietin factors. Gastritis following the operation may be of such severity that the gastric juice is not only neutralized but is no longer secreted, and achylia may then be associated with the absence of hæmopoietin and

neuropoietin factors. Clanwill and Hurt reported a case with duodenal ulcer with hyperechlorhydria, who developed achylia with pernicious anaemia and sub-acute combined

Year	Author	Percentage of cases with nervous symptoms

1934	Goldhamer, Bethell, Isaacs and Sturgis (1934) 90

degeneration eighteen months after gastro-jejunosomy. Salus (1932) has reported two fatal cases of sub-acute combined degeneration, but without anaemia which appeared 15 years after gastro-jejunosomy. In these cases free hydrochloric acid was present before but absent after the operations. Another three cases of pernicious anaemia following ileostomy developed sub-acute combined degeneration of the cord (Dixon, Burns and Griffin, 1925).

The ætiological relation between sub-acute combined degeneration and gastric carcinoma (Waterfield, 1923; Shackle, 1923; Hurst, 1923; Garvey and Stern, 1924; Waterfield, 1927; Hurst, 1929; Simpson, 1931; Fisher, 1934), benign tumours of the stomach (Balfour and Henderson, 1927) have been suggested. Hurst (1929) believes that the carcinoma was probably secondary to chronic gastritis, and that the sub-acute combined degeneration of the cord and anaemia resulted from the achlorhydria, which was present before the carcinoma developed. He (1924) reported a case of typical sub-acute combined degeneration with the blood picture of Addison's anaemia, complete achlorhydria and glossitis with gastric carcinoma. In cases of carcinoma of the colon and stricture of the small bowel the hæmatological picture of pernicious anaemia (Becker, 1930; Hurst, 1933) with the

clinical signs of sub-acute combined degeneration (Grinker, 1926; Meulengracht, 1929; Little *et al.*, 1929) has been observed. Meulengracht (1929) has reported a series of 20 cases; the strictures were usually tuberculous and involved the lower part of the small intestine, occasionally the upper part of the colon. The hæmatological picture, the nervous symptoms and the bone marrow were all typical of pernicious anæmia and achylia was present in all the cases. Woltmann and Heck (1937) reported a case who had multiple intestinal fistulas and a faecal fistula following appendectomy; later the blood picture of pernicious anæmia and symptoms of sub-acute combined degeneration were observed. Salus (1932) has reported a case who had stenosis of the small bowel, acquired achlorhydria, a normal blood picture and signs of sub-acute combined degeneration of the cord. This suggests that the stomach plays an important part in the development of sub-acute combined degeneration of the spinal cord in cases of pernicious anæmia. Moreover, the anæmia following the intestinal fistula, stricture of the small intestine, carcinoma of the colon, and of the stomach responds to liver treatment with a reticulocyte crisis and prompt regeneration of the blood (Meulengracht, 1929; Little *et al.*, 1929; Taylor, 1930).

Achylia gastrica is a constant finding in sub-acute combined degeneration as in pernicious anæmia. According to Vanderhoof (1923) and Hurst (1932) there is an almost invariable association of gastric achylia with combined sclerosis of the spinal cord. They suggested that the fundamental cause of spinal sclerosis may be achlorhydria. Sylapka (1922) has reported a case in which the interval was two years before the first signs of sub-acute combined degeneration of the cord and achlorhydria appeared. Greenfield and O'Flynn (1933) have reported a series of 45 cases with sub-acute combined degeneration of the cord, achlorhydria was present in all the cases. Pernicious anæmia was present and 14 per cent of the cases had red cell counts exceeding 4.5 millions. Achlorhydria is a constant finding in both pernicious anæmia and sub-acute combined degeneration of the cord, although a case reported by Hurst (1933) in which degeneration of the cord with Addison's anæmia was associated with normal gastric secretion following chronic obstruction of the ileum. Ford-Robertson (1929) has investigated the incidence of achlorhydria in psychosis; he found that hypochlorhydria was present to a much greater extent than in normal persons.

HEREDITARY AND FAMILIAL

The familial occurrence of achlorhydria with sub-acute combined degeneration of the cord and with Addison's pernicious anæmia has long been known. Records have been published of about 140 families in which two or more members

were affected with pernicious anæmia with or without sub-acute combined degeneration, and 59 families in which one of these diseases occurred in one or more members of a family and achlorhydria in others (Wilkinson and Brockbank, 1931; Conner, 1930).

Wilson (1912) reported a case of a woman with sub-acute combined degeneration, her two maternal aunts had died of pernicious anæmia. Another patient with severe pernicious anæmia but with slight sub-acute combined degeneration, had a brother who was found to have sub-acute combined degeneration with achylia but with perfectly normal blood (Hurst, 1928). Many other such cases have been reported.

ÆTIOLOGY

The ætiology of the changes in the nervous system remains obscure; however, neurotoxin as the causal factor is suggested (Camac and Milne, 1920). While as a result of experimental evidence it is believed that the manifestations in the cord may result from a vitamin deficiency (Gildea *et al.*, 1930; Suzman, 1931). Many authors have long considered the view that pernicious anæmia and sub-acute combined degeneration were due to hæmolysis by toxins elaborated by organisms in the stomach and intestinal tract (Hurst, 1924; Carlson, 1923). Hurst stated that the infection of the intestine with a hæmolytic streptococcus is an essential factor in the production of Addison's pernicious anæmia and degeneration of the spinal cord; but intestinal infection cannot account for the fact that predigested liver is ten times as effective as raw liver in pernicious anæmia (Reimann, 1931).

Vitamin B: Vitamin B is known to have anti-neuritic principle and its deficiency may result in various neural lesions. Zimmerman and Burack (1934) have found that the lesions were produced by deficiency of the heat-stable portion of vitamin B, but not produced by vitamin-B₁ deficiency. The resulting disease is generally associated sooner or later with pernicious anæmia. Neural lesions of peripheral or central type are sometimes associated with chronic alcoholism (Strauss, 1935) with chronic diarrhoea and with gastro-intestinal lesions (Strauss, 1934). Thus the symptoms may much resemble those of pernicious anæmia, but the progress of the neural lesions in a complicated case of pernicious anæmia is arrested by adequate administration of liver extracts especially when given by parenteral injection (Strauss *et al.*, 1935), the development of the neural lesion is undoubtedly a nutritional deficiency. Manifestations of disorder of the nervous system in vitamin-B₁ deficiency are so striking that the condition in experimental animals is usually called polyneuritis. However, the nervous symptoms appear late in the deficiency and rats kept without vitamin B₁ may die without nervous lesions (Wolbach,

1937). Recent work seems to indicate that the fat content of the diet may be an important factor in vitamin B₁ in relation to the production of polyneuritis in rats (McHenry, 1937; Salmon and Goodman, 1937). The profound functional disturbances of the nervous system and speedy recovery with treatment indicates that vitamin B₁ is directly concerned in the physiology of the neurons. Wolbach (1937) showed that in pellagra lesions of the nervous systems are found; they are not pathogenic in character but are degenerative in type. In long-standing cases of pellagra degeneration of the spinal cord may occur. Petri and his associates (1937) showed that the removal of the stomach in young dogs and swine developed a chronic fatal disease regarded as pellagra, with changes in the nervous system. Since these changes are resistant to oral treatment with vitamin B₂, but rapid improvement followed administration of neutralized stomach juice; the symptoms seem attributable to the loss of a specific gastric factor. They believe that neuropoietin principle is probably the anti-pellagra factor.

The production of polyneuritis in dogs given a diet deficient in vitamin B has been shown by Cowgill (1912). Gildea and his associates (1930, 1935) carried out the experiments on dogs and produced neurological signs, and lesions of the spinal cord, somewhat resembling those of sub-acute combined degeneration, were produced by the prolonged restriction of vitamin B in the diet. The affected dogs always had free hydrochloric acid in the gastric contents and oral administration of vitamin B prevented the progress of the neural symptoms. While with the rare exceptions the use of vitamin B in the treatment of the neural lesions in pernicious anaemia with achylia gastrica has been unsuccessful (Fouts *et al.*, 1934; Fouts *et al.*, 1932). Zimmerman and Burack (1932) have failed to confirm these observations. Somewhat similar changes in dogs with chronic black tongue and macrocytic anaemia have been observed (Crane-Lillie and Rhoads, 1934). In some cases of sub-acute combined degeneration there is also evidence of polyneuritis. Douthwaite (1936) suggested that the health of the peripheral nerves is, like that of the spinal cord, dependent upon an adequate supply of neuropoietin or of some allied substance from the gastric or duodenal mucosa. McAlpine (1929) showed that the neurotoxin associated with pernicious anaemia may attack all parts of the nervous system, cerebrum, spinal cord and peripheral nerves. In sub-acute combined degeneration peripheral nerves are generally affected. Hurst (1928) has stated that in three patients with pernicious anaemia the achlorhydria may have resulted from chronic alcoholism. Strauss (1935) has stated that his 10 cases who were suffering from alcoholic polyneuritis were given spirituous liquor, concentrated vitamin B, and liver extract by

parenteral injection. Improvement in the polyneuritis occurred in every person. Ossenkopp (1931) reported a case of chronic alcoholism with symptoms of multiple sclerosis, but the pathological picture was atypical. It has been suggested that vitamin-B₁ content of the blood is normal in cases of pernicious anaemia with or without sub-acute combined degeneration, and in these conditions poor therapeutic results have been found (Ungley, 1938; Sinclair, 1938; Rowlands and Wilkinson, 1938).

Vitamin A: In animals fed with diets deficient in vitamin A there may also develop abnormal neurologic signs. That the curative and preventive effect of whole liver in sub-acute combined degeneration is due to a fat-soluble factor, probably vitamin A, one therefore quite distinct from the water-soluble factor which is curative of the blood condition in pernicious anaemia (Suzman *et al.*, 1932; Mellanby, 1930). Mellanby (1930) described the production of degenerative changes in the central nervous system by diets rich in cereals and deficient in vitamins. With the diet deficient in vitamin A, white maize resulted in degenerative changes, while with the yellow maize the cord was normal.

Recently, Einarson and Ringsted (1938) showed that adult rats fed on diets free from vitamin E for a long time developed certain neurological disturbances. When the treatment of wheat-germ oil was begun within the first week of the special feeding paresis did not develop, but if the treatment was begun after eight weeks of this feeding paresis appeared six to eight weeks later. Although there is evidence that lack of vitamins A and B may be followed by certain degenerative changes in the nervous system, these vitamins alone are ineffective in the treatment of sub-acute combined degeneration.

The substance in liver extract necessary for the nutrition of the nervous system is distinct from the haemopoietin factor. Ungley and Suzman (1929) stated that the lesions in the nervous system are probably the result of a conditioned deficiency. They found that the liver had a direct effect on the neurological manifestations; completely destroyed axis cylinders in the central nervous system cannot regenerate however, but the function of the cord may improve. Grinker and Kandel (1934) have shown that liver therapy is not efficacious in improving or preventing degeneration in the nervous system complicating pernicious anaemia, and that liver cures the mental symptoms of pernicious anaemia which are usually caused by the anaemia. Sturgis and his associates (1927) showed that in a series of cases with pernicious anaemia and sub-acute combined degeneration, the administration of liver or liver extract produced no change in neurological signs, although the regeneration of the blood was observed. Baker, Bordley and Longcope

(1932) reported that 61.5 per cent of their cases showed improvement and 36 per cent failed. Farquharson and Graham (1930) stated that liver therapy has a specific effect on the nervous lesions, arresting their progress in virtually all cases and causing marked improvement in large numbers. However, complete recovery has not occurred after definite nervous manifestations. Many authors have reported distinct improvement in the nervous symptoms with large doses of liver (Minot and Murphy, 1927; Ungley and Suzman, 1929; Strauss and Castle, 1932; Starr, 1931; Bubert, 1928). While others have found improvement following the administration of desiccated stomach and liver extract (Smithburn and Zervas, 1931; Baker *et al.*, 1932), vitamins (Fouts *et al.*, 1932; Davison, 1931) and brain diets (Ungley, 1931). Ungley (1931) has found that the hæmopoietic potency of brain was only one-third of that of liver. Later, he (1932) stated that the effect of brain upon the nervous system is markedly greater than that of liver.

CONCLUSION

Neuropoietin principle is normally present in gastric secretion; its chemical nature is unknown. It has not been shown to be Castle's intrinsic or extrinsic food factors. It is secreted by the glands in the pyloric end of the stomach and by the fundus. It is stored in the liver and in the brain, and acts in the same way as hæmopoietin to form a substance essential for the normal nutrition of the central nervous system. It is clear that the possible effective factor in liver and in brain is not vitamin A, since liver and brain contain little or none of this vitamin.

In Addison's pernicious anæmia the intrinsic factor of Castle is almost always absent and this is generally associated sooner or later with the absence of neuropoietin principle. Castle's factor may be absent in cases with pernicious anæmia, but it may be present in other macrocytic anæmias; it is thus explained why the majority of cases of pernicious anæmia may develop sub-acute combined degeneration of the cord. In the anæmia of the macrocytic type, such as tropical nutritional anæmia, degeneration of the cord does not occur. Vaidya (1930) reported 149 cases with tropical pernicious-type of anæmia, only in one case were there symptoms of sub-acute combined degeneration.

Achylia gastrica is a constant finding in sub-acute combined degeneration as in pernicious anæmia. In experimental animals removal of the stomach, or cases of gastric atrophy with achlorhydria may not lead to pernicious anæmia or sub-acute combined degeneration of the cord, because there is a reserve in the duodenum to maintain function. In cases with pernicious anæmia in which the secretion of neuropoietin and hæmopoietin factors has not returned after treatment, the glands in the pyloric end and fundus of the stomach are degenerated, and

regeneration of the central nervous system is impossible after a certain degree of injury has occurred.

In animals fed on deficient diets there may also develop neurological signs and pathological lesions of the central nervous system resembling those seen in pernicious anæmia. However, there is no evidence that vitamins and the hæmopoietin and neuropoietin factors are in any way related. The hæmopoietin and neuropoietin factors contained in the liver or in the brain are extremely unlikely to have any connection with vitamin A, B or E. There is no evidence that toxins are absorbed in pernicious anæmia or in sub-acute combined degeneration of the spinal cord.

STATISTICAL YEAR-BOOK OF THE LEAGUE OF NATIONS, 1933-39

In the *Statistical Year-Book of the League of Nations*—which has appeared regularly since 1927, and of which the 1933-39 edition has just been issued—the Economic Intelligence Service provides a large and very varied amount of statistical information of interest both to specialists and to the general public.

The Year-Book deals with a large number of subjects. The statistical tables, carefully kept up to date, relating to the territories and populations of all countries in the world and to the natural movement of those populations, are of very general interest. The statistics of production, consumption, trade, exchange

injection should not be given in any circumstances. It is very easy to reduce the stools and produce apparent comfort by paralysing the intestine, but this may result in ileus and toxic absorption, which are practically always fatal in ulcerative colitis.

Various bismuth preparations and aromatic mixtures are in use. Of these the best are *mistura cretæ*, bismuth salicylate and aromatic sulphuric acid. They are of some value in the later stages and in mild forms.

Kaolin and charcoal are of some use with offensive stools. In any case they are probably harmless by the mouth and afford some satisfaction to the patient. True antiseptics can scarcely be expected to have any useful effect on the colon.

Emetine is definitely contra-indicated and should never be employed.

Numerous other drugs are in use and such preparations as soured milk. It is possible that some of these are of value in milder forms and slight relapses.

BLOOD TRANSFUSION

Blood transfusion is of great value in ulcerative colitis and its wider use in recent years is a most valuable advance in treatment. It is, of course, obviously indicated in cases of gross hæmorrhage. But it should also be used in a common group of cases where the hæmoglobin is reduced, say, to 60 per cent, a figure which does not involve any danger to life from anæmia but is sufficient to cause a grave diminution of strength.

VACCINES

Neither in severe or mild forms nor at any stage have I seen any good results from the use of vaccines.

DYSENTERIC SERUM THERAPY

Some good results have been recorded in cases with an acute onset following injections of anti-dysenteric serum. Its use rests on the belief that ulcerative colitis is initially due to infection with dysentery organisms. Good results are only obtained in very occasional cases and may be due to protein shock.

IONIZATION

Good results have been claimed for this method of treatment. It is probable that its action is mainly psychological.

COMPLICATIONS AND SPECIAL SYMPTOMS

Pain.—Pain is not a common feature except in the early stages with an acute onset. It may then be very severe before a motion. If there is much complaint of pain in later or more chronic forms one should think of psychological factors.

Vomiting.—This is a serious symptom as it may indicate involvement of the small intestine and stomach and interferes with nutrition. The diet perforce must be restricted, but no definite rules can be laid down.

Incontinence of fæces.—This, again, is a serious complication as it interferes with colonic treatment. No attempt must be made to continue colonic irrigation. If it persists operation may be unavoidable.

Paralytic ileus.—This is an extremely serious complication with a high mortality. It is especially liable to develop after injections or overdose with morphia. For a time the patient usually asserts that he is much better, and he appreciates the reduction in the number of stools. Treatment should be on the usual lines for this abdominal complication. It need scarcely be stated that the passage of the so-called long rectal tube is barbarous, useless and dangerous.

Anæmia.—The correct treatment for anæmia in the acute stages is by blood transfusion. Iron is rarely well tolerated and the risk of disturbing the appetite and digestion is considerable.

Nervous disturbances.—The psychology of the patient must be considered in all types of ulcerative colitis. An initial acute attack, a relapse or resistance to treatment may all be associated with nervous disturbance.

Clinical variations.—Mild cases may be met with in which treatment may be ambulatory and the frequency of the motions controlled by simple measures. There is a difficult group of cases in which an occasional stool is passed, typical of ulcerative colitis, the remaining motions being normal. This may be seen in the later stages of treatment, suggesting that a portion of the intestine is still in active ulceration. It is not uncommon as a chronic form existing over long periods in young women, and in this case there is frequently a psychological factor. Such cases may be resistant to all treatment, but they are usually compatible with considerable activity.

Constipation.—This is best dealt with by temporarily relaxing any active treatment. A colonic wash is not always sufficient. Liquid paraffin is usually successful, but cases are by no means uncommon in which it disturbs the digestion and in other cases seepage may be troublesome. Taxol is a very good gentle laxative. Obviously, no strong aperient is permissible.

Arthritis.—This is by no means an uncommon complication. It clears up spontaneously and no special treatment is indicated.

SEQUELÆ

The commonest sequelæ are hæmorrhoids, fistula and fissure which need appropriate treatment. Polyposis is a rare complication which develops in very chronic cases. It may produce severe hæmorrhage and apart from this there is some risk of the development of malignancy. Polypi consequently have always to be treated. The cautery is sufficient if they are within reach.

SURGICAL TREATMENT

Operation should not be regarded as the routine treatment for there is no doubt that the usual surgical procedures directed towards resting and washing the affected colon are unsatisfactory. Such operations, however, may save a life which would be lost under medical treatment. Steady deterioration in the general condition, loss of weight, severe hæmorrhage and possibly persistent abdominal pain are indications for operation. There are many forms of operations designed to rest and wash the colon, but in all cases it is essential that the opening should be made above the diseased area.

Undoubtedly, the most satisfactory surgical procedure is resection of the affected colon. The mortality is by no means as high as might be expected, even when the entire colon is removed, and the operation has proved successful in cases which appear to be desperate. Obviously such an operation must not lightly be advised, but the possibility should be borne in mind in all chronic cases in which there is evidence that a large portion of the colon is involved.

Prevention and Treatment of Bed-Sores

By V. ZACHARY COPE, M.S., F.R.C.S.

(From the *British Medical Journal*, 8th April, 1939, p. 737)

A BED-SORE is an ulcer or area of impaired nutrition of the skin and subcutaneous tissues due mainly to the too great or prolonged pressure on those parts of the body that are most subject to pressure when the patient lies in bed. The body is not homogeneous in consistency nor does it lie evenly on any ordinary mattress which may support it; some parts of the skeleton project and take more than their fair share of the weight, and it is over such projections that bed-sores form. If the weight of the body could be evenly distributed over the whole of the surface that is in contact with the mattress, bed-sores would be exceedingly rare. The nearest approach to this even support results when a plaster-mould of the posterior half of the body is fashioned and the patient is allowed to lie on the mould. If the plaster be correctly made it is possible for the patient to lie on it for months without changing position or having any attention paid to the back, and at the end of that time

the skin of the back will be quite intact and healthy. Consideration of this fact throws much light upon the principles which should guide us in the prevention and treatment of bed-sores.

A bed-sore is really a form of pressure-gangrene, but though pressure is the main factor there are important subsidiary points to be considered. These subsidiary factors may be external or internal. External factors consist chiefly of slight traumata caused by the friction of clothes or irregular rucks in the sheet upon which the patient lies; and the irritation of the skin by urine, feces, or sweat. Quite apart from the irritation which may be caused by these, the moisture softens the superficial epithelium and makes it less resistant to pressure. The internal or constitutional factors consist of those diseases which lower the blood pressure or diminish the vitality and blood supply of the tissues. This is a large group of conditions comprising all debilitating diseases and a very important group of nervous diseases (especially paraplegia) in which the absence of sensation and the impossibility of normal vasomotor reaction make the prevention of bed-sores extremely difficult. It is also clear that emaciated patients whose bones project more than usual will be more prone to develop bed-sores.

The most common positions for bed-sores are in the region of the sacrum, over the prominences of the scapulae, the heels, and the back of the head, and over any vertebral spine which may be at all prominent. A sore may develop over the elbow or the iliac spine, and if the patient lies on his side a sore may appear over the great trochanter. It must be remembered that the nutrition of any part which is subjected to continuous pressure may suffer, and the medical attendant must keep watch for the effects, which will vary according to posture the patient may adopt.

The diagnosis of a well-developed bed-sore is, as a rule, quite easy, for the unhealthy ulcer which often spreads from some focus of pressure tells its own tale. It is much more important to recognize the earlier stages when the sore either threatens or is inevitable. When a sore is threatening to develop the skin will be found to be slightly reddened and tender; the redness will disappear on digital pressure and will reappear when the pressure is removed. This follows from the fact that the first stage is merely an erythema or congestion and the vascular supply is still intact. When a sore is inevitable the colour changes to a dusky or purplish red, and since the circulation in the part is arrested the pressure of the finger will not be followed by the phenomenon described above: there is capillary stasis. When this stage has been reached it is inevitable that some necrosis of tissue and consequent ulceration will result. In some cases a sore begins as a small crack in the skin from which ulceration spreads.

PREVENTIVE MEASURES

In no department of medicine is the proverb 'prevention is better than cure' more applicable than in the case of bed-sores. In the great majority of cases it is possible, and customary, to prevent them; and with well-trained nurses it is usually considered a reflection on their nursing capacity if a sore develops. The nurse prevents bed-sores in three ways: first, by avoiding undue pressure on any one part; secondly, by preventing the infliction of minute traumata; and, thirdly, by improving the circulation and increasing the resilience and elasticity of the skin. It is the doctor's part to improve the general condition and vitality of the patient, and to give advice when sores threaten or form.

Avoidance of undue pressure

For this purpose it is necessary to see that the mattress is firm enough to prevent the body sinking deeply into it, and yet soft enough to allow it to be moulded to the contour of the patient's body. A firm hair mattress is customary. In those cases of very ill or feeble patients where special care is necessary a water-bed is sometimes used. The water-bed, which

is put on top of the ordinary mattress, must only be half filled with water (at 100°F.). A fully filled water-bed would be as objectionable as a very hard mattress, and one less than half filled would allow too much sagging of the body. Water-beds are rather troublesome and many prefer to use a pneumatic mattress or, more commonly, air-cushions instead. Circular air-cushions or circles of sorbo-rubber are used to take the pressure off any particular part; air-cushions must be only half filled with air, and must form a large circle, with the affected part in the centre. Too small a cushion may cause oedema of the included part and actually do harm. Cushions must be well covered with linen. There are on the market some horseshoe-shaped rubber cushions (Dunlopillo), that are designed to obviate oedema of the included part.

Change of posture in bed

Normal people always change their position in bed as soon as any discomfort indicates the need for it. Sick patients cannot do this, so the nurse must do it for them in order to avoid too prolonged pressure on any one part. In altering the position of a patient the body ought not to be rolled over, but rather lifted gently so as to effect the change.

Avoidance of minute traumata

The greatest care must be taken to avoid slight injury to the skin when the bed-pan is used; in persons who are recovering from an anaesthetic and in those who are paraplegic it needs a careful hand and a vigilant eye to see that the skin is not damaged by hot-water bottles. Dry bread-crumbs or rucks in the sheet or draw-sheet may cause unnecessary friction. The rather rough way in which an abdominal binder is pulled from under a patient who is about to undergo an abdominal operation might cause dangerous friction to the sacral region; in such cases the patient ought to be gently raised while the nurse withdraws the binder.

Maintenance of normal condition of skin

This is done by keeping it clean and dry, by massaging and in some cases hardening it. In an ordinary patient the pressure-points are attended to twice daily (morning and evening) and after the bed-pan has been used. In feeble patients and in those who are incontinent the toilet must be done every four hours or even every two hours. The special areas, particularly the sacral region, are washed and gently and firmly massaged by the palm of the hand and the pulp of the fingers working in the lather formed from white Windsor or other good soap; after five or ten minutes' massage the soap is washed off, the skin dabbed with a dry clean towel, and some form of spirit is then rubbed into the skin. Usually ordinary methylated spirit is used, but eau-de-Cologne or even brandy may be employed if wished. After the spirit has been well rubbed in, the part is thoroughly dusted with talcum powder or similar preparation.

With incontinent patients it is of the utmost importance to keep the skin dry. The draw-sheet must be changed frequently and frequent attention given to the skin. Usually a preparation of equal parts of zinc ointment and castor-oil is applied with the object of keeping the skin dry, but such ointment is disliked by some in that it may soil the linen; this soiling may be avoided if the ointment be used sparingly. When a bed-sore is threatening every effort must be made to change the position of the patient so that the affected part is relieved of pressure, and the skin must be attended to at least every two hours.

TREATMENT OF THE INEVITABLE BED-SORE

When, by the discoloration of the skin and the demonstrable lack of capillary circulation, it is recognized that a bed-sore is inevitable, it is recommended by Latimer that the area be hardened by means of tannic acid solution. A 5 per cent aqueous solution is sprayed on at half-hourly intervals and the part dried. Air provided by suction from electric light source. This method of

treatment is less likely to be followed by sepsis than when the part is treated by fomentations. The dried slough will ultimately separate and leave an ulcer, which can be treated by one of the methods here described.

When a definite sloughing ulcer is present it must be specially treated in one of the following ways. For small and even moderate-sized there is no doubt that the application of elastic adhesive plaster, as advocated by Carty, is useful.

'Two pieces of elastic adhesive plaster, one over the other, are applied so that the bed-sore and the skin surrounding it for at least an inch are covered. The elastoplast is left in position as long as it will adhere—usually, in the early stages when the discharge is plentiful, twelve to forty-eight hours. It is then replaced by similar pieces of adhesive plaster, and this is repeated until healing is complete.'

If the elastoplast treatment is adopted it is essential to see that the whole of the ulcer and a considerable area of healthy skin round it are completely covered up; and the plaster must not be removed to see how the ulcer is progressing. Only when it becomes loose should it be replaced by a new piece or pieces. By means of this treatment large and deep ulcers may sometimes be induced to heal. Latimer points out that the elastoplast method is not suitable for cases in which there is involvement of bone, virulent infection, or profound necrosis of tissue. If the elastoplast treatment is not adopted the above-described tannic acid application may be tried.

There are still many who prefer to treat bed-sores by the older-fashioned methods of astringent or antiseptic applications. There are many to choose from. Dakin's solution helps to separate the sloughs and clean up the surface of the ulcer. Hypertonic saline solution (5 to 10 per cent) has been recommended. A dilute solution of aluminium acetate is astringent and slightly antiseptic; Burow's preparation is a 5 per cent solution of this chemical, and is too strong—it must be diluted ten times before application. Good results have been claimed also after application of dusting powders containing rhubarb or catechu, dermatol or aristol. I hold no particular brief for any of these applications, but think that healing may take place with any of them and many others. The chief point is to keep the surface of the ulcer clean and free from pressure. When the ulcer is quite clean the application of lotio rubra hastens healing.

In addition to local applications healing may be hastened by the use of artificial sunlight or ultra-violet rays to the part. When there is a large slough it may be advisable to cut it away, but that is about as much surgical intervention as is ever required.

Diet in General Practice with Special Reference to the Amount of Food Given

By L. COLE, M.D., F.R.C.P.

(From the *British Medical Journal*, 22nd January, 1938, p. 158)

THE results of treatment by diet are often very different from those aimed at. Sometimes this is because the main idea has been obscured in a mass of comparatively unimportant detail, but more often it is because alteration in one direction has led to deficiency in another. Such errors cannot be avoided unless the constituents of a normal diet are constantly kept in mind, and for this reason these will first be briefly given.

THE NORMAL DIET AND ITS CONSTITUENTS

For a diet to be normal it must contain enough food. Perhaps it is because this is so obvious that it is so often forgotten. The actual amount required by different people varies much more than books on physiology lead one to suppose. The diet for an 'average man' approved by a committee of the Royal Society consists of 100 grammes of protein, 100 grammes of fat, and 500 grammes of carbohydrate. This has a total energy value of 3,400 calories. Many

people can maintain health on a much smaller allowance of food or of protein than this, and the tolerance and requirement of fat also vary greatly. The amount of carbohydrate varies very widely, too, but it should always be enough to ensure normal metabolism of fat, and for this the ratio of carbohydrate to fat should not fall below that indicated by Woodyatt's formula: $F = 2C + \frac{1}{2}P$. Finally, in considering quantity it must be remembered that excess may be as harmful as lack.

The importance of vitamins seemed at one time to be overstressed. Recent work, however, by Harris Archer and Graham, and others has shown that minor degrees of vitamin deficiency are all too common, and that they often occur in patients on special diets in which the normal vitamin requirement has been overlooked. Diets given in gastric cases are extremely liable to be deficient in vitamin C, and low-residue diets in vitamin B, unless this particular danger is realized and the deficiency corrected. In all diets, therefore, the possibility of such deficiency must be considered.

Every diet must contain certain inorganic constituents, and of these iron, iodine, calcium, and sodium are the ones of which a deficiency may occur. When it does it may result from failure of absorption or excessive loss rather than from actual deficiency in the diet. Witts and others have shown how rapidly many forms of anemia respond to large doses of iron, but that such response only occurs when the amounts given are far and above those taken normally. Lastly, every normal diet should contain sufficient roughage, hard food to develop the jaws and keep the teeth healthy, and water.

DEFICIENCY THROUGH DIETING

Restriction of diet in one direction may lead to deficiency in another, and the most common of these untoward effects is the result of reducing the food to an amount below the optimum necessary for health. In some cases the reduction is so severe that actual weakness from lack of food occurs. This may happen with diets given for various conditions. In the artificial feeding of infants with diluted milk it is very easy to bring the caloric value too low without realizing it, unless calculations are made to check this. The following is an example of such a mistake:—

A premature infant weighing six pounds failed to put on weight. She had been given six feeds in the day, each feed amounting to three ounces, consisting of one part milk and two parts water and half a drachm of sugar; half a drachm of cod-liver oil emulsion was also given daily.

For rough-and-ready reckoning it should be remembered that the child of 6 months or under requires approximately 50 calories per pound, and that one ounce of cow's milk or human milk produces 20 calories, one drachm of sugar 15 calories, and one drachm of fat 30 calories. In this case the calorie requirements were 300. The child was actually getting six ounces of milk, 120 calories; three drachms of sugar, 45 calories; and half a drachm of fat, 15 calories; total, 180 calories, or about 120 short of the theoretical requirement. The replacement of water by another ounce of milk per feed, bringing the total calories up to 300, rapidly produced a normal gain in weight. Minor deficiencies through too great dilution of milk are not uncommon, but they can easily be avoided if such a method of calculation is used. When breast-fed children fail to thrive the cause is often too little milk. In such cases the importance of test feeding to find out exactly how much food is being given cannot be over-emphasized.

Diets for gastric and duodenal ulcer cases afford another example of quantity deficiency, particularly those given in the early stages, consisting mainly of milk. In order to maintain strength and weight and promote healing it may be well to give 2,000 or more calories a day. One pint of milk produces approximately 400 calories, so that five pints will be necessary if the diet consists entirely of milk. This diet is difficult and trying for the patient, and so far as the

ulcer is concerned there is no reason why more concentrated fluid feeds, variously flavoured and thickened, should not be given. Cream and olive oil, for example, are high-caloric foods of great value. The difference between a diet of, say, 1,000 calories and one of 2,000 may be that between healing and failure to heal; while the lower diet, if continued for long, may make convalescence slower than it need be. Discretion must be used, particularly at the very beginning of treatment, but fuller diets are nearly always well tolerated.

In patients with chronic nephritis and high blood pressure it is not unusual to find that all red meat has been forbidden. If the diet previously has been a very full one and has contained much red meat it is clearly rational to reduce this in order to throw less strain on the kidneys, liver, and heart, but in so doing it must be remembered that to cut off the main source of protein drastically is often to cause a feeling of weakness and depression that is worse and more disabling than the actual symptoms of the disease. Moderate restriction is sound, but the benefit resulting from drastic restriction is at the best nebulous, and is not justified if it produces symptoms. Many patients who have been thus severely treated feel fitter and better in every way when their burdens are lightened. If a patient has been accustomed to take meat three times a day he will probably feel better if he is allowed it once a day rather than not at all.

DIET IN DIABETES

In the treatment of glycosuria, whether diabetic or not, excessive dieting is one of many pitfalls. It is very important to make a correct diagnosis before symptoms are masked by what may be excessive, even unnecessary, restriction. Many cases of glycosuria are innocuous and do not need treatment, but are dieted unnecessarily; the symptom has been blindly treated without an investigation of its cause. The following is an extreme example of this mistake:—

A man of 40 was sent to the out-patient department suffering from mild hyperthyroidism and chronic pulmonary tuberculosis. Sugar had been found in his urine, and because of this finding his loss of weight had been attributed to diabetes mellitus, and a diet of 100 grammes of carbohydrate, 75 grammes of protein, and 150 grammes of fat given. The glycosuria was actually a symptom of hyperthyroidism, and with his raised metabolism, chronic infection, and restricted diet he was going rapidly downhill. A change to a high-caloric diet with plenty of carbohydrate led to rapid improvement and ultimately complete recovery.

Except in severe cases of diabetes mellitus it is important that investigations of blood sugar and urine should be made before the diet has been altered, so that the correct diagnosis may not be masked by treatment. Once the diagnosis of diabetes mellitus has been made the test of good treatment is whether the patient feels absolutely fit, is able to do full work, and maintains a constant weight. If a normal blood sugar and freedom from glycosuria can also be maintained so much the better; but fitness and efficiency are more important than these, and some of the latter standards may have to be sacrificed. Extreme introspection or neurasthenia is too heavy a price to pay for a normal urine, and in such cases some laxity is preferable. It is desirable, however, that freedom from ketosis should always be maintained.

In diabetics, as in normal people, there is extreme variation in the amount and type of food required, and the best diet for a particular patient must ultimately be found by trial. In patients over 45 the question whether insulin is necessary often arises. In such borderline cases the diet which they can take and still be sugar-free is barely enough to keep them fit and active. Again decision is by trial and error, but it is a pity to allow patients to struggle on without insulin, under-nourished but sugar-free, when with insulin they could take a fuller diet and feel well. When they develop an infection many such patients will have glycosuria and need insulin; they should

therefore be taught how to use it, so that they may take it at once without fuss should occasion suddenly arise. In old people with diabetes it is undesirable to reduce the blood sugar suddenly either by diet or by insulin. Many feel better with a permanently raised blood sugar, and the danger of over-dieting even when glycosuria is present must not be forgotten.

DIET IN OTHER CONDITIONS CAUSING OBESITY

In contrast to the diets in which inadvertently too little food is given I would direct attention to those in which the aim is reduction of weight. 'Reducing' diets have a wide application, not only for the treatment of obesity as such but in the treatment of other conditions in which a moderate increase in weight often escapes notice. It is of those 'other conditions' that I want particularly to speak.

From a theoretical standpoint increase in weight seems likely to lessen physical capabilities in certain directions. The mere addition of a stone means that more work has to be done, throwing extra strain on the circulatory and respiratory systems for which there is no return. To those of sedentary occupation or inclination this may tip the scales on the side of increasing weight and decreasing activity, a vicious circle which once started, may be difficult to break. The deposit of superfluous fat, particularly around the hip and shoulder girdles and in the abdomen, leads often to degeneration of posture, which predisposes to bad breathing and visceroptosis. Bad breathing, a lax abdominal wall, and diminished activity interfere with the return of blood to the heart. This is normally brought about by muscular movement of the limbs, the descent of the diaphragm during inspiration—which, when the abdominal wall is of good tone, raises the intra-abdominal pressure and drives blood towards the heart—and the negative pressure in the great veins towards the end of inspiration. This effect is shown by the tendency of such patients to develop varicose veins and hæmorrhoids. And yet how often does one see varicose veins treated but no attempt made to correct the obesity posture or visceroptosis. Further, the output of the heart is dependent on the venous return, so that the whole circulation is likely to suffer. Increased deposit of fat and diminished activity also has its effects on joints, muscles, fasciæ, and tendons, allowing adhesions to form which interfere with the blood supply, so paving the way for chronic rheumatic affections, such as 'lumbago', 'neuritis', and 'sciatica'.

RELATIVE CARDIAC INSUFFICIENCY IN OBESITY

Proger and Denny have made an experimental study of the factors responsible for the so-called relative cardiac insufficiency in obesity. They compared three obese with three normal patients, with the following results:—

The vital capacity in the obese was from 12 to 25 per cent below normal, according to whether height or surface area standards were used. The respiratory minute volume, while the same in both groups at rest, showed an average increase of one-third in the obese during mild exercise. The respiratory rate per minute in the normal and obese during mild exercise was 17 and 18 respectively. The oxygen consumption was definitely greater in the obese during exercise, and was more than could be accounted for by the greater work associated with the extra weight or higher respiratory rates. The resting pulse rate tended to be higher in the obese.

If obesity produces these effects in patients whose hearts are healthy its effect on those with a weak or damaged myocardium becomes clearer. The opinions of many distinguished physicians might be quoted in support of the view that obesity tends to shorten life. Rolleston says: 'The long-lived are usually spare and seldom fat, having been thin since middle age'. It is also supported by life insurance figures. MacLaren says that cerebral apoplexy, Bright's disease, nephritis, cardiac disease of uncertain nature, and diabetes mellitus all give a much higher mortality in those over weight. It is supported as well by the biologist.

Robertson and Ray have shown, in white mice, that those with relative paucity of tissue accretion in late life tend to be long-lived. From the evidence there is little doubt that in many the tendency to put on weight is a degenerative change. This is a particularly important point, because in numerous cases it can be prevented.

THE CAUSES OF OBESITY

Before considering treatment of obesity, however, it is essential to discuss its causes. Du Bois has divided cases into two main groups: endogenous or constitutional, in which there is frank endocrine abnormality; and exogenous, in which no such cause can be recognized. These groups merge into each other, and while the extremes can be recognized there are a large number of cases in which it is impossible to say how far the exogenous or the endogenous factors predominate. The tendency to put on weight is one of the most variable characteristics in different people; one can eat as much and do as little as he likes and his weight does not vary; another has but to eat an extra potato or omit his daily walk and his weight rises. Such tendencies often run in families, and may be likened to other hereditary metabolic disorders such as diabetes or gout. Whatever may be the primary cause, it is certain that in most people gain or loss depends on supply and demand, the amount of food absorbed and the amount of energy used. The effect of variation of food and exercise differs so much in different people that it is impossible to predict with certainty the result of a particular regime in a particular patient, and the effect must be determined by trial and error. In nearly all cases, however, a decrease in the fat-forming elements of the food—carbohydrate and fat—with increased exercise will cause a loss of weight, but the degrees of each required must be found by experiment.

A word must be said here on the use of thyroid gland in obesity. This is valuable when there is hypothyroidism and in some patients who put on weight at the menopause. When, however, there is no thyroid deficiency thyroid extract should only be used as an adjunct to treatment by diet, massage, and graduated exercises, and in most cases it is unnecessary. If these measures fail, then a careful trial of thyroid is advisable. Treatment of obesity with thyroid alone is usually unsuccessful unless the dose is pushed, and then it may be dangerous. Poulton suggests that many obese subjects, far from possessing a low metabolism, have it slightly raised. To give thyroid in such conditions without reducing weight may mean that still more work is thrown on a heart which has already too much to do. The patient remains fat and feels very ill.

METHOD OF REDUCING WEIGHT

Reduction of weight may be said to depend on the application of these principles. Fat formation is prevented by having less fat and carbohydrate in the diet, and metabolism is stimulated by giving protein and increased exercise. Only if these methods fail should artificial stimulation of metabolism by thyroid be resorted to. In actual practice this means that the diet is made up mainly of lean meat, fruit, and green vegetables, with only enough sugar, starch, and fat to prevent feelings of weakness or hunger. In putting patients on such a diet it is wise to begin slowly so that adjustment to the change may be gradual: the degree of change depends on the individual, but once a diet is found that produces a steady fall in weight there is no need to make it more drastic. The scales are the best guide.

The following example shows the method in practice:—

A woman, aged 50, with obesity; weight 14 st. 6 lb. There was no evidence of endocrine abnormality. On 3rd July, 1937, she was put on a diet of lean meat, fruit and green vegetables, with 140 grammes of carbohydrate per day. By 31st July there had been no change in weight, and the carbohydrate was reduced to 80 grammes. On 14th August her weight was

14 st. 5 lb., so the carbohydrate was further reduced to 60 grammes. On 16th October her weight had fallen to 13 st. 4 lb.

Increase in exercise should also be gradual. Graduated exercises, designed where necessary to improve breathing and posture, should if possible be taught and supervised by a qualified masseuse, supervision being relaxed as the patient becomes proficient. It is essential that such exercises should be done regularly at home every day. Other exercises, such as walking for prescribed distances, cycling, or riding, are valuable, and the degree to which these are necessary must be found by trial in each case. The scales and the patient's feelings are again the best guides. In patients with excessive abdominal fat a surgical belt is often a great aid to increased activity.

In ten consecutive patients with uncomplicated obesity treated as out-patients at Addenbrooke's Hospital during the last year for periods ranging from twelve to forty-eight weeks the average loss of weight was 25 lb. each. Reducing diets and graduated exercises were used in all cases, and in only two were small doses of thyroid given in addition.

Occasionally patients do not respond, and these often come from families in which there is a strong familial tendency to obesity. Before beginning treatment careful inquiry into the family history will be of importance as a guide to prognosis.

EFFECTS OF TREATMENT BY WEIGHT REDUCTION

Treatment by weight reduction is often of the greatest value when obesity occurs either as an incidental association or as the result of some other condition, and perhaps unnoticed by the patient at all. Sometimes the actual increase in weight above the normal is comparatively slight and would pass unobserved in a healthy patient. In association with a weak myocardium or a raised blood pressure, however, it becomes profoundly significant, because it may be the one factor which is treatable, and may turn the scales in favour of recovery. Some conditions in which the possibilities of weight reduction should always be considered are: chronic bronchitis, myocardial weakness and degeneration, high blood pressure, viscerotaxis, and fascial rheumatism. In such the methods used are the same as those in simple obesity. Their application is, however, a much more delicate problem. Changes of diet and exercise must be made more slowly and must be carefully adjusted to the individual case. Before beginning treatment it is best to make a patient describe in detail his diet and daily life. This provides a basis which may be gradually modified on the lines mentioned. In cases of heart disease and high blood pressure it may be best in the early stages to use massage as a prelude to increased activity.

ILLUSTRATIVE CASES

The following are examples showing some types of case to which the above methods are applicable:—

Case 1.—A general practitioner, aged 47. The patient gave a history of chronic bronchitis with increasing winter cough for five years; breathlessness on exertion, getting worse for six weeks; and pain over the præcordium on exertion, with fluttering sensations in the chest. Examination in April, 1936, showed the presence of chronic bronchitis and some emphysema. Clinically his heart was found to be enlarged and one inch to the left; there were a tick-tack rhythm and frequent extrasystoles: the resting pulse rate was 90. There was slight cyanosis; the blood was 140/90, and the electrocardiogram normal. His weight was 13 st. 12 lb.; height 5 ft. 7 in. The diagnosis was chronic bronchitis and myocardial weakness. Treatment consisted in gradually reducing the diet and increasing exercise, reducing smoking, and ordering the wearing of an abdominal belt. On 20th May the patient was much better and his weight was reduced to 13 st. 5 lb. On 7th July there were no symptoms; his weight was then 12 st. 2 lb., and he was doing much of his practice on a bicycle. The improvement has since been maintained.

Case 2.—A mau, aged 62, complained on 31st July, 1937, of increasing breathlessness on exertion and slight giddiness of several months' duration. Examination revealed arterio-sclerosis, a blood pressure of 190/110, and a pulse rate of 46. An electrocardiogram showed a 3:1 heart-block. His weight was 14 st. 3 lb. After ten days' treatment with massage, mild graduated exercises, and reducing diet his weight had fallen to 13 st. 4 lb. The symptoms of breathlessness and giddiness had disappeared, and he felt much better.

Case 3.—A woman, aged 52, had had increasing noises in the head and breathlessness on exertion for eight months, with a recent gain in weight. Examination revealed arterio-sclerosis and a high blood pressure (200/110). Her weight on 17th July, 1937, was 12 st. 8 lb. Treatment consisted in reducing the diet and the prescription of half a grain of thyroid extract each day. After three months her weight had fallen to 10 st. 8 lb., the blood pressure was 200/94, the symptoms had disappeared, and she felt well.

Case 4.—This patient, a woman, aged 44, complained of pain in the back on exercise and a 'bearing-down feeling' in the stomach. On examination her doctor found sugar in the urine. When seen on 1st June, 1937, she was very obese, her weight being 16 st. 9 lb. There was a heavy deposit of fat round the shoulders and hips, and the abdomen was protuberant. The urine gave 2 per cent of sugar, but no acetone. The resting blood sugar was 2 per cent. Treatment took the form of massage and exercises to reduce weight and improve posture and breathing, with a reducing diet, and an abdominal belt was worn. After three months' treatment the symptoms had gone, the urine was sugar-free, the resting blood sugar 0.12 per cent, and the patient's weight 14 st. 6 lb.

Case 5.—A woman, aged 51, stated that following an attack of influenza in February 1937, she developed shortness of breath and precordial pain on exertion. These symptoms persisted. When examined on 19th May, 1937, her heart was not enlarged, but the quality of the sounds was poor; the blood pressure was 150/80. The abdominal wall was lax, with visceroptosis. Her weight was 10 st. 10 lb. and she was rather fat. Treatment was by means of an abdominal belt, massage, and exercises to reduce weight, and a moderate reducing diet. After five months' treatment her weight was 10 st. 1 lb. She was better in every way and her symptoms had almost gone.

CONCLUSION

By treatment on the above lines it is often possible to delay the effects of degenerative processes that occur after middle life. To be successful, however, such treatment must be begun early and must be thorough. If it is left too late comparatively little can be done. Both the recognition and the treatment are in the hands of the family doctor, whose opportunities are unrivalled.

The Treatment of Septicæmia

By LIONEL E. H. WHITBY, C.V.O., M.C., M.D., F.R.C.P.

(From the *Medical Press and Circular*, Vol. CCI, 17th May, 1939, p. 470)

SEPTICÆMIA is caused by the entry of bacteria into the blood stream. Here the organisms multiply and by reason of this multiplication exert a toxic action on the tissues of the body. In pyæmia there is septicæmia with a tendency for the circulating bacteria to aggregate and form infarcts which readily proceed to abscess formation. The primary lesion in pyæmia is usually an extensive focus of infection such as osteomyelitis. Septicæmia and pyæmia have to be distinguished from bacteriæmia in which condition bacteria are present in the blood stream, and do indeed multiply there so that they may be demonstrated by blood culture. The blood stream invasion, however, is only a preliminary phase of a more defined disease process. Examples are the bacteriæmia characteristic of the early stages of typhoid fever and sometimes

the invasive phase of lobar pneumonia. The treatment of septicæmia and pyæmia is to a large extent influenced by the primary cause as well as the nature of the infecting organism. As to cause, septicæmia is frequently cryptogenic and this perhaps the most fatal form of the disease, may appear quite suddenly in apparently healthy subjects or as a terminal condition in debilitated persons afflicted with such diseases as nephritis. In other cases the cause and the portal of entry are clear. In parturient women the large raw area of the placental site provides a ready portal of entry. In some, the injury caused by a dental extraction or by unwise surgical interference with a vascular, but not purulent, inflammatory lesion may cause infection of the blood stream; in others the inoculation may be accidental from a cut or prick. The organisms most commonly responsible are hamolytic streptococci of group A, occasionally groups B, C and G, and *Staphylococcus aureus*, but almost any organism may bring about the disease in debilitated subjects or in those who receive a large and virulent inoculation; in puerperal septicæmia anaerobic streptococci are sometimes responsible. The treatment of septicæmia and pyæmia *per se* should include: (1) General measures, (2) Chemotherapy, (3) Specific therapy, and (4) Surgical measures. The sooner treatment can be instituted the greater is the chance of success, and though an essential prelude to rational treatment is the establishment of the exact nature of the infecting organism by blood culture, empirical treatment, based on clinical probability, should be undertaken whilst investigations are being carried out.

(1) *General measures.*—The patient should be at complete rest in bed. Food should be as generous as the diminished appetite allows, whilst the fluid intake should be as high as possible. Fever should be controlled by tepid sponging and not with antipyretic drugs. Fresh air is essential; the sick room should be light and airy and, when practicable, nursing in the open air is to be recommended. Small blood transfusions, not exceeding 250 c.c., are beneficial and may be given every 5 to 7 days in chronic cases.

(2) *Chemotherapy.*—The discovery of the sulphanilamide group of drugs has greatly improved the prognosis in septicæmia. Dosage, route of administration and choice of compound vary with each individual case. As a general principle, a large initial dose of the appropriate compound is desirable in order quickly to obtain an adequate concentration of the drug in the blood. When facilities are available it is as well to check this point by a blood estimation a few hours after beginning treatment. The blood content should reach and be maintained at not less than 10 mgm. per cent. If this level is not reached with an oral preparation, then subcutaneous, intramuscular or intravenous injections should be used as a supplement. The oral preparations serve for most purposes and they have the advantage of being slowly and continuously absorbed over a period of time, thus maintaining an adequate blood level. Soluble preparations for injection or injection of sulphanilamide itself (which is soluble in water to the extent of 1 per cent) are more rapidly absorbed than oral preparations, but they are also excreted more rapidly. Numerous injections are therefore necessary if a soluble preparation is used as the sole method of treatment. Intravenous administration is rarely required; only Soluseptasine (*vide infra*) is at all well tolerated. The parenteral route has to be used when swallowing is not possible, when nausea and vomiting are prominent symptoms, when absorption from the alimentary canal is inadequate, and for immediate treatment in urgent and neglected cases.

The duration of treatment has to be decided for each individual case. Where these drugs are effective the result is usually obvious within a few days. If no action is noticed within ten days it is useless to pursue treatment with that particular drug. Prolonged courses tend to cause a fatal agranulocytosis and a number of other distressing and sometimes dangerous symptoms. If the first course of ten days is not entirely effective an interval of three days should be

allowed before beginning a fresh course. For the second course a change of preparation is often an advantage. When dangerous symptoms caused by the drug arise during the course of treatment the blood stream can be rapidly cleared by inducing diuresis with water.

Choice of preparation.—(a) *Oral.*—Sulphanilamide (sold also under trade names, which include Sulphonamide p, Streptocide, Colsulanyde, Prontosil album) is markedly active against most *B. hæmolytic* streptococci, meningococcus, gonococcus, *Bact. coli* and *Cl. welchii*, but is relatively inactive against staphylococcus and has no appreciable action on pneumococcus and *Streptococcus viridans*. The drug is well tolerated by the mouth and is probably the compound of choice for empirical treatment of a suspected hæmolytic streptococcal infection.

A total daily dose of 1 g. per 20 lb. of body-weight (maximum 5 g.) should be given, for the first two days, in equally divided doses administered four hourly. Children require a 50 per cent larger dose in proportion to body-weight than do adults. After two days the total daily dose should be reduced by a gram and after a further two days the remainder of the course of ten days should be at the rate of 3 g. per day.

The benzyl compound, 'Proseptasine', has approximately the same range of activity as sulphanilamide, but is less soluble, less toxic and less powerful. This compound is of great value for, and is more suitable for, the treatment of less serious diseases than septicæmia.

The pyridene compound 'M. & B. 693' has a wider range of activity than sulphanilamide, being effective against all the organisms influenced by the latter as well as against pneumococcus, whilst it is more effective against staphylococcus and *Streptococcus viridans*. The pyridene compound is therefore the best drug for empirical use when the nature of the infecting organism is uncertain from the clinical aspect. A dosage similar to that for sulphanilamide may be used. A certain number of cases have difficulty in taking the drug by the mouth; vomiting and nausea may prohibit adequate treatment. In all cases it is advisable to powder the tablets and suspend the powder in milk; in this form the drug is usually well tolerated. M. & B. 693 is not sufficiently soluble in water to be administered as a subcutaneous solution, but a suspension in olive oil may be given by this route. The sodium salt of M. & B. 693 is extremely soluble and effective; it is at present in the experimental stage of trial and is not available for general use.

(b) *Parenteral.*—'Prontosil soluble' (Bayer) is made as a 5 per cent solution. The total daily dosage for the first ten days should be 0.5 c.c. per 1 lb. of body-weight (maximum 60 c.c.); this should be divided in six doses administered during each 24 hours. 'Soluseptasine' (May and Baker) may be given in higher dosage (maximum 200 c.c.) and is the only preparation suitable for intravenous administration. Owing to the rapidity with which the soluble preparations are excreted it is necessary to make frequent injections in order to maintain the blood concentration at an efficient level. Hence, it is now usual to rely on soluble preparations only. The main uses of these compounds are to supplement an oral preparation, especially when there is much nausea and vomiting or if there is poor absorption as shown by a blood estimation; they are also useful at the beginning of the course of treatment.

(3) *Specific therapy.*—When appropriate sera are available they may be used to supplement chemotherapeutic treatment. There is considerable evidence that the sulphonamide group of drugs exert their action by inducing bacteriostasis and that the final elimination of the infection requires the co-operation of the immunity mechanisms of the host. For this reason, therefore, small doses of the concentrated antitoxic sera of streptococcus, staphylococcus and *Clostridium welchii* should be used when there is much toxæmia. Except in chronic low-grade infections with little or no

febrile and general reaction, vaccines are useless and even dangerous.

(4) *Surgical measures.*—Any abscess which develops in the course of the disease should be treated by drainage when fully mature. The formation of an abscess is sometimes a favourable event which serves to localize the infection. The production of an artificial fixation abscess by injection of 1 drachm of turpentine beneath the skin is favoured as a method of treatment by some authorities.

PROPHYLAXIS IN THE CASE OF WOUNDS

Most medical men must at some time have thought about what they would do were they to receive a wound when dealing with an obviously infected patient or when doing post-mortem. As the result of such an injury one of three things may happen. Firstly, the infecting organism may be inoculated direct into the blood stream, in which case, owing to the speed of the blood stream, no local measure, however quick, can prevent the dissemination. Secondly, the infecting organism may be inoculated into the tissue spaces and either give rise to a local abscess or cause an ascending lymphangitis, which, in due course, may result in septicæmia. Thirdly, nothing may happen, either because no inoculation is made or because the organism is quickly overcome. As an immediate measure there is much to be said for the encouragement of free bleeding by the application of a light tourniquet, the free-flowing blood being washed away under a tap. Caustics and strong antiseptics should be avoided as these cause tissue necrosis which encourages the growth of any implanted organisms; iodine or acriflavine may be used, but the best dressing, if such is available, is either hypertonic saline or hypertonic magnesium sulphate, which stimulate an outward flow of lymph. However busy a medical man may be he is taking an unnecessary risk if he does not cease work at once and go to bed for at least 24 hours with the affected part immobilized; he should, of course, remain in bed if there is the slightest evidence of local or general reaction at the end of this time. During the period in bed a prophylactic course of the appropriate sulphanilamide drug should be taken in full dose and this should be continued unless everything appears well at the end of 24 hours.

Reviews

DIET IN HEALTH AND DISEASE.—Edited by Sir H. Rolleston, Bt., G.C.V.O., K.C.B., M.D., F.R.C.P., and Alan A. Moncrieff, M.D., F.R.C.P. 1939. Published on behalf of the Practitioner (5, Bentinck Street, W.1) by Eyre and Spottiswoode (Publishers), Limited (6, Great New Street, E.C.4), London. Pp. 382. Price, 14s.

THIS is the fourth book in this practical series to be issued, and in many ways it is the most useful.

The first chapter, which is introductory, is an excellent one. It is written by Dr. V. H. Mottram whose work on dietetics is well known; he claims that the physiological approach to the subject of dietetics is more suitable than the chemical. Though he admits that the broad division into energy-producing, body-building and body-protecting substances is a vague one, he considers that it is much more easily understood and remembered than the more exact chemical classification of food substance into proteins, fats, carbohydrates, calcium, iron and other minerals, vitamins A to E with their numerous sub-division, etc.

The book is divided into chapters on diet in individual disease (e.g., pulmonary tuberculosis), groups of diseases (e.g., nervous and mental disorders), symptomatic states (e.g., constipation), and special physiological states (e.g., pregnancy).

The chapter on diet in tropical diseases is on the whole a good one. The author has had many years' experience in dieting patients suffering from tropical

diseases, in a temperate climate. In discussing diseases such as sprue, dysentery and kala-azar, he has given a good account of the best practice, but in other, chronic diseases, such as leprosy, he is obviously at a loss and has beaten round for isolated remarks by writers on these diseases, which, taken from their context, are not really very helpful. He has further confused matters by including certain diseases which are aetiologicaly associated with the eating of poisonous substances; this subject is outside the scope of the book, as well as being inaccurate in some cases.

Professor Cathcart in his introduction mentions the young hospital-trained general practitioner, who orders a 'light diet' for his patient and sincerely hopes that he will get past the door before he is questioned further on the subject. Now at least he will be able to look it up when he gets home, in case, after a successful escape on his part, the patients' relatives should telephone for the information.

It is a very valuable addition to the practitioners' reference library. Its use in this country will naturally be limited, but as the principles as well as the practice are there, a little adaptation only will be necessary.

SILICOSIS AND ASBESTOSIS.—By Various Authors. Edited by A. J. Lanza, M.D. 1938. Oxford University Press, London. Pp. xxvi plus 439. Illustrated. Price, 25s. Obtainable from Oxford University Press, Bombay and Calcutta

THE death and morbidity rates are much lower in the advanced industrialized countries of the west than in India, but the credit is not all on one side, and against the better housing and better food of the industrial worker is the direct result of the industry itself on his health.

We have scarcely begun to study this aspect of industrial advance in India, but we shall have to do so, and it is fortunate for us that much ground work has been done in Great Britain and in America, and also in South Africa where conditions are closer to those in this country.

This monograph on pneumoconiosis, or pneumoconiosis as they prefer to call it in this book, is a valuable summary of our present knowledge on this subject, written by six experienced workers in this field: four are American and two British.

There is a good historical summary. The subject is dealt with on a geographical basis; the seven countries mentioned are Great Britain and her three largest colonies, Germany, Italy, and the United States. The subsequent chapters are on aetiology and symptomatology, x-ray diagnosis (the writer shows a tendency to wander from his subject, e.g., he includes a paragraph on the sedimentation rate), pathology, experimental pathology, the occupational, preventive and legislative aspects in Great Britain (by Dr. E. L. Middleton, H. M. Medical Inspector of Factories), and the public health and economic aspects in the United States.

The subject is clearly and concisely presented by the various writers, and the book is well illustrated. It is a book that is essential for the sanitarian, and especially the industrial hygienist, in this country, and every medical officer who works amongst miners should certainly obtain a copy.

THE TREATMENT OF RHEUMATISM IN GENERAL PRACTICE.—By W. S. C. Copeman, M.A., M.D., B.Ch. (Cantab.), F.R.C.P. (Lond.). Third Edition. 1939. Edward Arnold and Company, London. Pp. viii plus 276. Price, 10s. 6d.

THIS is the third edition of a book that has already earned a reputation as a sound guide for the general practitioner in dealing with rheumatism and allied conditions.

The author claims that his book is the first of its kind, that is, a book by a general physician in which the whole subject of rheumatism is treated impartially. No one form of treatment is emphasized, as is the case in so many books on the subject; this enthusiast advocates vaccines, that hydrotherapy, another light,

and yet another diathermy; then there are the searchers for septic foci, the bowel washers, the chemotherapists, and dietitians. Dr. Copeman weighs them all up and if the mixture is more like weak tea than strong wine, it is precisely for this reason that it is better for reader's patients.

This new edition has been largely rewritten and brought thoroughly up to date and we can very strongly recommend it to the general practitioner in this country.

RHEUMATISM.—By B. S. Nissé, M.D. (Lond.), M.R.C.P. (Eng.). 1938. John Bale Medical Publications, Limited (85, Great Titchfield Street, W.1), London. Pp. 168. Price, 5s.

THE author, who is one of the honorary physicians to that excellent institution the British Red Cross Clinic for Rheumatism, Peto Place, has written a concise, readable and practically useful book on rheumatism, in its widest sense. The book is divided into three parts; these are on rheumatic fever, that is, acute and sub-acute rheumatism, fibrositis, and arthritis, respectively.

The treatment advocated for each condition is in conformity with modern views on the subject, and the author has no particular specialization which he emphasizes at the expense of other forms of treatment.

The book is published in a very attractive form, with an artistically very satisfactory page. It is bound in unvarnished cloth which provides no temptations to fauna of the Indian desk and open bookshelf.

PRINCIPLES OF DIAGNOSIS, PROGNOSIS AND TREATMENT: A TRILOGY.—By R. Hutchison, M.D., LL.D., F.R.C.P. Second Edition. John Wright and Sons, Limited, Bristol. Pp. 53. Price, 3s. 6d.

THIS now almost classical essay has been reprinted and published in a very attractive form.

It is a small book that could be read in an hour, but every word is worth remembering and acting upon.

The volume would make a very suitable gift for a medical man.

THE COMPLETE PEDIATRICIAN PRACTICAL, DIAGNOSTIC, THERAPEUTIC AND PREVENTIVE PEDIATRICS. FOR THE USE OF MEDICAL STUDENTS, INTERNES, GENERAL PRACTITIONERS AND PEDIATRICIANS.—By W. C. Davison, M.A., D.Sc., M.D. Second Edition—Completely rewritten. 1938. The Duke University Press, Durham, N.C. Pp. vi plus 250. Price, \$3.75.

THIS book might equally well have been called 'potted paediatrics'. It is a really American production, with its characteristic efficiency and its equally characteristic limitations. For quick reference it would be hard to beat, and the information is on the whole accurate, but it is perhaps 'potting' a little too much to say that 'as the symptoms of kala-azar and sleeping sickness are the same as those of malaria, the diseases will be described together'. However, a surprising amount of useful information has been crowded into the two columns of each page. It takes a little time to get used to finding diseases: it is not, for example, immediately clear why one should look under the gastro-intestinal group for yellow fever, under skin conditions and contagious diseases for tick typhus, and under circulatory, metabolic and glandular diseases for malaria. But there is a good index and one learns.

The author doesn't hold with the niceties of Latin grammar and prefers the forms *Stegomyia fasciatus* and *Aedes aegyptus* to the more usual ones.

This is a second edition and we quite agree that the changes are improvements: also the subject-matter has been brought completely up to date. The format is an attractive one. It is a book we can recommend to those to whom it is dedicated—medical students, internes, general practitioners, and paediatricians.

CLINICAL DIAGNOSIS BY LABORATORY METHODS: A WORKING MANUAL OF CLINICAL PATHOLOGY.—By J. C. Todd, Ph.B., M.D., and A. H. Sanford, A.M., M.D. Ninth Edition. 1939. W. B. Saunders Company, Philadelphia and London. Pp. 841, with 368 illustrations, 29 in colours. Price, 27s. 6d.

THIS is the ninth edition of a book that is already well known amongst laboratory workers in this country. It forms a comprehensive guide to the diagnostic laboratory worker and is a useful book of reference for the research worker. The methods that are described include those relating to the sputum, the urine, the blood, both cytological and chemical, the gastric contents, the faeces, pus, and puncture fluids. There are chapters on animal parasites, serodiagnostic and bacteriological methods, vaccines and skin tests.

It is four years since the last edition was published and considerable revision has been carried out. A number of new methods have been added and obsolete ones dropped out. A new classification of the anæmias is given. As the authors say 'many classifications... are proposed but none of them are (sic) entirely satisfactory'; we agree, but we don't think Ottenberg's, the one they give, is the best.

It is a useful book which we can conscientiously recommend to both laboratory workers and physicians.

THE ESSENTIALS OF PHARMACOLOGY, MATERIA MEDICA AND THERAPEUTICS FOR MEDICAL STUDENTS.—By D. M. Macdonald, M.D., F.R.C.P.E. 1938. Henry Kimpton, London. Pp. 279. Price, 7s. 6d.

THE essential idea which suggested an addition to an already large number of textbooks is to impress on the student the wisdom of a wider and more practical knowledge of pharmacy and materia medica, in order to cultivate intelligent prescribing on the one hand, and to avoid slavery to proprietary preparations and stereotyped formulæ on the other.

For this reason, stress is laid on the importance of suitable and pharmacological combination with avoidance of incompatibility. In addition to a chapter on the latter, incompatibilities are indicated under their respective headings.

There is also introduced a series of prescribing notes suggesting the most appropriate or, it may be, palatable presentation of some particular drugs. The substance of the *B.P. Addendum* of January 1937 has been incorporated.

This is a handy little volume that practitioners in India will find useful.

CHEAP BALANCED DIETS (FOR BENGALLEES).—By Nishikanta Ray, B.A. 1939. Published by the University of Calcutta, Senate House, Calcutta. Pp. xii plus 125

THIS small book (which is the Calcutta University Jubilee Research Prize thesis) deals with the nutritional aspects of various articles of Bengali dietary and planning of cheap balanced diets suitable for Bengalees.

The book is divided into four chapters. Chapter I deals with dietary constituents and their contribution to nutrition; chapter II discusses the quantitative food requirements; chapter III summarizes the dietary value of the principal foodstuffs, and chapter IV is devoted to the planning of cheap balanced dietaries to satisfy the physiological needs of the individual at different ages, and, in the case of women, during pregnancy and lactation. The author has shown that a well-balanced diet for an average Bengalee adult can be devised at costs varying from Rs. 4-12 to Rs. 5-12 per month in Calcutta and at a cheaper rate in the smaller towns and villages.

The book will prove useful to those interested in nutritional problems in India. The general public would derive a good idea of the principles of dietetics 'so that the money available for food will be properly spent so as to get the largest return in food value and

progressive changes in the traditional dietary habits will be brought about'.

P. C. S. G.

A TEXTBOOK OF MALARIA CONTROL.—By V. Venkat Rao, M.R.San.I. (Lond.), and V. Ramakrishna, B.Sc. (Hons.), A.R.San.I. 1939. Published by V. Venkat Rao, Senior Malaria Inspector, B. N. Railway, Waltair, R.S. Pp. x plus 149. Price, Re. 1

THE book has undoubted value, but it has many misprints, and mis-statements that require detailed discussion which the space allotted to this review would not allow.

URINE EXAMINATION AND CLINICAL INTERPRETATION.—By C. E. Dukes, M.Sc. (Lond.), M.D. (Edin.), D.P.H. (Lond.). 1939. Oxford University Press, London and New York. Pp. xv plus 403. Illustrated. Price, 25s. Obtainable from Oxford University Press, Bombay and Calcutta

Of human excretions urine has always exerted the most popular appeal. A large percentage of the classical portraits of physicians, some of which are reproduced in this book, show their subjects holding a flask of urine up to the light, and the loquacious patient has usually a great deal to say about his or her urine and unhesitatingly expresses approval or disapproval of it on the strength of its appearance and smell. The reviewer has always been as sceptical about that wise look on the physician's face, as he is of his patient's assurance that his urine is 'quite alright'. There is remarkable little to be learnt from the macroscopic appearance of urine, compared with the information that can be obtained from its chemical, microscopic, and biological examinations, which form the subject-matter of this book.

This book is a concise yet comprehensive study of the subject. Often more than one method is described but the author has not attempted to include all known methods and has confined himself to the more practical ones. Recent works on hormones and vitamins are taken into consideration, and there is one of the best descriptions of the Aschheim-Zondek and Friedman tests that we have yet seen. These two tests are illustrated by a number of plates which show the results of the tests in the way that no words can do. Some of the methods of estimating the excretion of vitamins in the urine are given but one would scarcely rely on a book of this kind for the latest information on this kaleidoscopic subject. Under the heading of B₁ estimation the author has described a method of estimating porphyrin in the urine without any cross reference to a modification of this test which he described earlier in the book.

The author has earned the reviewer's special gratitude by avoiding that horrible word 'urinalysis'.

The book is an important addition to the library of the laboratory worker and physician. It is a book that one would recommend the senior student to purchase; he will find it invaluable to him in his house appointment and later when goes into practice.

AN INTRODUCTION TO HUMAN ANATOMY.—By Clyde Marshall, M.D. Second Edition. 1939. W. B. Saunders Company, Limited, Philadelphia and London. Pp. 388. Illustrated. Price, 12s.

THIS should be a good book for use in teaching higher school classes and junior science students the main facts of human anatomy including microscopic anatomy or histology. It is not recommended for the medical student, however, because with the limited time available in the average medical course it is necessary for him to plunge direct into a detailed study of the subject without spending any time on acquiring a smattering of the whole subject as a preliminary to deeper study, and this is all this book can supply.

It is copiously illustrated with figures taken from all the best-known anatomy and histology textbooks, the only two figures noticed without any acknowledgment being nos. 40 and 42.

On the whole it is clearly written but on page 330 the following confusing misprint occurs. 'Normally the maxillary process and the frontonasal process fuse completely and leave no trace of their former existence as separate parts. Occasionally, however, the fusion is incomplete and an opening between the *left is left*' (reviewer's italics).

The complete 'Americanization' of the spelling of ordinary words is an objection to use of the book in countries where English spelling is employed.

A SYNOPSIS OF SURGICAL ANATOMY.—By A. L. McGregor, M.Ch. (Edin.), F.R.C.S. (Eng.). Fourth Edition. 1939. John Wright and Sons Limited, Bristol. Pp. xii plus 664. Illustrated with 648 figures. Price, 17s. 6d.

As Sir Harold Stiles said in the foreword to the first edition of this book, with the advances in anaesthesia and the reduction of the importance of the time element, the field of the surgeon is so vast that a surgical anatomy has to cover the whole human frame. Therefore, a synopsis of anatomy in which the surgical point of view is maintained is really the only way to meet the requirements of the under-graduate student, or the doctor studying for higher surgical qualifications.

If this was true in 1932 it is truer to-day. This book has reached its fourth edition; the third was issued in 1936 and was reprinted in 1937. No important changes have been made but there has been a general revision.

The descriptions are clear and concise and there are useful line drawings almost on every page. It is published in a practical and attractive format. It is a book that will prove invaluable to the student and to the surgeon in this country.

A SYNOPSIS OF REGIONAL ANATOMY.—By T. B. Johnston, M.D. Fourth Edition. 1939. J. and A. Churchill Limited, London. Pp. xxi plus 462. Illustrated. Price, 12s. 6d.

THIS is the fourth edition of a book with an already established reputation, so little need be said about it.

It is a synopsis and is therefore meant for use only for revision. The point is emphasized in the preface; by revision the author means *revision*, and in order to make quite sure that the reader has a clear mental picture of the part, which he should have acquired during his dissection work, the author gives no illustrations. Where this picture is not clear enough to be assisted by this book, the student must go back to the dissecting room. He has made an exception with reference to the central nervous system, for obvious reasons, and has given some good diagrams, a number of which are new to this edition.

Reviews of previous editions of this book have been consistently laudatory. No drastic change has been made in the present edition, but the whole text has been revised and some additions have been made.

It is a book that will be very useful to the student in this country.

CLINICAL PATHOLOGICAL GYNÆCOLOGY.—By J. Thornwell-Witherspoon, B.S. (Princeton), B.A. and M.A. (Oxon.), M.D. (Johns Hopkins). 1939. Henry Kimpton, London. Pp. 400. Illustrated with 271 engravings. Price, 30s.

As the author points out in his preface, this work is not a complete gynæcological textbook. It does, however, take the reader over the main field of gynæcological pathology in a manner which is at once concise, clear, and easy to follow. In rather less than four hundred pages of interesting reading, augmented by excellent drawings, photographs, and photomicrographs, the author has described all the usual pathological conditions peculiar to women, including modern ideas on hormonology.

In general, clinical signs and symptoms are omitted intentionally, and only some elements of treatment are

given. Lists of references to modern authorities are included under their appropriate sections.

The book is arranged on an anatomical basis, and a section describes some of the disorders of early pregnancy, *i.e.*, abortions, ectopic pregnancy, hydatidiform mole, and chorion epithelioma.

A chapter is devoted to an interesting and instructive discussion on the relationship between estrogenesis and carcinogenesis.

The printing and general arrangements are good, and the price reasonable.

Those interested in gynæcology will appreciate this book as a readable and reliable work on the pathology of this speciality.

K. S. F.

HUMAN PATHOLOGY: A TEXTBOOK.—By H. T. Karsner, M.D. Fifth Edition. 1938. J. B. Lippincott Company, Philadelphia and London. Pp. xii plus 1013, with 18 illustrations in colour and 443 black and white. Price, 45s. Obtainable from Messrs. Butterworth and Company (India), Limited, Calcutta. Price, Rs. 33-12

KARSNER'S Pathology is well known to every student of medicine. Within a short period of about twelve years five editions have come out which only speak for the immense popularity of this book. The edition has been profusely illustrated and exhaustive references have been added at the end of each section which are very helpful to the readers who want to learn more about the subject. In dealing with the subject-matter under each section the author has avoided the practice of presenting a cut-and-dried view of any subject, but has very wisely introduced different view points by various workers, so that students can get a comprehensive idea of the subject. The inclusion of recent work has made the edition up-to-date. A helpful procedure has been offered to the readers in the way of affixing a very brief summary at the beginning of each chapter which will enable readers to see the contents at a glance.

The author has first described the general pathological processes and thereafter has given his attention to the special pathology of each section under systematic heads, which will enable the students to follow easily the application of the general pathological changes to a particular system as modified by its anatomical and physiological considerations.

Under the heading of disturbances of circulation, the subject of infarction has been dealt with before thrombosis and embolism; if the arrangement had been reversed it would have been easier for the student to grasp the subject. Some of the subjects which do not come under the purview of pathology in its strictest sense have been described in full, *viz.*, the biology, morphology and chemical composition of *M. tuberculosis* and the interpretation of the Wassermann reaction, whereas the author has very shortly dealt with some of the sections, *e.g.*, the pathology of tumours of the adrenals and muscle tissue. While describing the kala-azar spleen the author states that the parenchymatous cells of the liver might contain parasites (p. 521) which, however, requires modification. In our experience at least, the parasites were never found within the liver cells.

Apart from these minor defects the author should be congratulated for the excellent mode of presentation of the subject and the general get-up of the book.

B. P. T.

BERGEY'S MANUAL OF DETERMINATIVE BACTERIOLOGY: A KEY FOR THE IDENTIFICATION OF ORGANISMS OF THE CLASS SCHIZOMYCETES.—By David H. Bergey, Robert S. Breed, E. G. D. Murray and A. Parker Hitchens. Fifth Edition. 1939. Baillière, Tindall and Cox, London. Pp. xi plus 1032. Price, 45s.

THIS is a book which is indispensable to all serious students of bacteriology and is constantly required in bacteriological laboratories. Bacteriologists owe a debt of gratitude to the late Professor Bergey for having undertaken the preparation of the Manual. It is

interesting to recall that the first edition of the Manual which was published in 1923 tabulated descriptions of 832 species of bacteria with reference to the original place of publication of 1,577 descriptions; the present edition contains description of 1,335 species with a reference to the original place of publication of 5,600 descriptions. The size of the Manual is now more than double that of the first edition. There are many additions in this edition as compared with the fourth edition. The number of families in the order of Eubacteriales has been increased from the three found in the previous editions to twelve. Nine new generic names are used. This new edition will be welcomed as a most useful book of reference by all bacteriologists.

C. L. P.

(a) **STUDIES ON THE HEALING OF FRACTURES—WITH SPECIAL REFERENCE TO THE SIGNIFICANCE OF THE VITAMIN CONTENT OF THE DIET.**—By John Hertz, M.D. 1936. Published by the Oxford University Press, Humphrey Milford, London. Pp. 286. Illustrated. Price, 15s. Obtainable from the Oxford University Press, Bombay and Calcutta

(b) **EFFECT OF CHRONIC VITAMIN-E DEFICIENCY ON THE NERVOUS SYSTEM AND THE SKELETAL MUSCULATURE IN ADULT RATS: A NEUROTROPIC FACTOR IN WHEAT GERM OIL.**—By L. Einarson, M.D., and A. Ringsted, M.D. 1938. Oxford University Press, London. Humphrey Milford. Pp. 163. Illustrated. Price, 12s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta

(a) This is a beautifully produced monograph on a very important subject which all dietitians should have in their libraries.

Vitamin-C deficiency interferes very seriously with the healing of fractures, and the mechanism of this interference is shown in this monograph. Vitamin A does also, but to a less extent, and the detrimental effect of either hypo- or hypervitaminosis-D is considerable.

(b) This is another report on dietetic research in the State Vitamin Laboratory, Copenhagen. It presents important conclusions on the parts played by different vitamins in normal physiology. One important conclusion is that vitamin A has little or no neurotropic action, and that vitamin E, the 'neurotropic factor of wheat germ oil', is more important in this connection than vitamin B₁, or any component of the vitamin-B complex.

Both monographs are irreproachably translated by Dr. Hans Anderson.

HANDBOOK OF BACTERIOLOGY: FOR STUDENTS AND PRACTITIONERS OF MEDICINE.—By J. W. Bigger, M.D., Sc.D. (Dub.), F.R.C.P.I., M.R.C.P. (Lond.), D.P.H., M.R.I.A. Fifth Edition. 1939. Baillière, Tindall and Cox, London. Pp. xvi plus 466. Illustrated. Price, 12s. 6d.

THE fact that Bigger's bacteriology which was first published in 1925 has gone through five editions and that three of the editions have been reprinted demonstrates its popularity. This popularity is well deserved. Amongst the smaller textbooks on the subject Bigger's bacteriology can be confidently recommended as one of the best suited to the needs of medical students and the busy medical practitioner who desires to consult a book on bacteriology. The subject-matter is presented in a simple, concise but lucid manner. This is one of those books which a teacher of the subject can confidently recommend to his students. In the present edition definite advances in bacteriology have been incorporated, and, by judicious pruning and condensation, the present edition is only twelve pages more than its predecessor. Amongst the changes that we welcome is the introduction of the newer nomenclature based on what might be called the English modification of Bergey's nomenclature adopted by Topley and Wilson.

C. L. P.

THE STREPTOCOCCAL TENDENCY.—By J. D. Hindley-Smith, M.A., B.Ch. (Cantab.), M.R.C.S., L.R.C.P. 1939. H. K. Lewis and Company, Limited, London. Pp. iv plus 32. Illustrated. Price, 1s.

THE streptococcus in one or another of its forms has been repeatedly implicated directly or indirectly in many disease conditions. The disease-producing capabilities of certain members of the genus *Streptococcus* are bewildering, from simple sore throats to fatal septicæmia. The streptococcus must be considered to be the bacterial enemy no. 1 of man. Careful study has been made of these organisms and there exists an extensive literature on streptococci.

The reviewer had hoped to find something of interest in this 32 paged booklet with its quaint title, but in this he was sorely disappointed. The author after drawing attention on page 1 to the long list of diseases caused by the streptococcus sets out six questions on page 2 which he answers in page 3. The rest of the book is devoted to vaccine therapy with a few remarks on the importance of the blood sedimentation test, non-specific therapy and a small paragraph on 'amino-benzo-sulphonamide'. It would not be worth while to review here the numerous statements in this little booklet which are not supported by any experimental work and many of which cannot be either proved or disproved. The whole work is an ill-fitting mosaic of facts, half truths and many conjectures. The four photographs which illustrate this book have no intrinsic value. The legends under illustration A and B are self-contradictory. The author has seen fit to extol the value of vaccine therapy in streptococcal prophylaxis without any convincing data. It is pity, for such statements must retard progress in the search for prophylactic agents.

C. L. P.

THE ANÆROBIC BACTERIA AND THEIR ACTIVITIES IN NATURE AND DISEASE, A SUBJECT BIBLIOGRAPHY (IN TWO VOLUMES).—By Elizabeth McCoy and L. S. McClung. 1939. University of California Press, Berkeley. Cambridge University Press, London. Vol. I, Chronological Author index, pp. xxiii plus 295; Vol. II, Subject Index, pp. xi plus 602. Price, 50s.

THESE two volumes contain a classified index of 10,500 articles, monographs or other reports on anærobic bacteria published up to 1937 and some published in 1938. There are approximately 120,000 entries and the two volumes represent five years' work. In the first volume is a chronological list of all references arranged alphabetically within each year. In the second volume are the subject index sections. Full instructions for the use of these two volumes are given in volume I and with their help references to papers on any particular aspect in the study of anærobic bacteria can be obtained. The authors are to be congratulated in bringing together in these two volumes information which would be difficult to obtain readily. This work would be of immense value to all interested in anærobic organisms.

C. L. P.

EPIDEMIOLOGY IN COUNTRY PRACTICE.—By W. N. Pickles, M.D. (Lond.). 1939. John Wright and Sons, Limited, Bristol. Pp. viii plus 110. Illustrated. Price, 7s. 6d.

THIS is a book that should be read widely in India. It is the simple story of an English country practitioner's observations on the epidemiology of infectious diseases, as he has observed them in his practice. The unkind critic might say of it 'It is a book that would have been important had it been written one hundred and fifty years ago, but now it only tells us what we all know'. That is not true. If the book is read in the right spirit it conveys an important message and it reminds us that epidemiology in its beginnings was not a mass of tables, statistics, and formulæ as it appears to be to-day; it was the careful summation of experience relative to the spreading of disease.

This book will we hope inspire the young country practitioner to go and do likewise. Let him record carefully every incident connected with the transmission of disease from one person to another. Most of what he writes will be valueless, but from it he may one day be able to correlate a number of observations, individually meaningless, which will throw a ray of light where darkness ruled before. But he must not expect to do this under, say, twenty-five years.

MEDICAL INFORMATION FOR SOCIAL WORKERS.

—Edited by W. M. Champlin, A.B., M.D. 1938. Baillière, Tindall and Cox, London. Pp. xi plus 529. Illustrated. Price, 18s.

THE thirty chapters and two appendices in the book have been contributed by nine teachers at the Western Reserve University, U. S. A. The book is primarily intended 'to enlighten the beginners in social work to enrich the medical knowledge at the command of the more mature social workers'.

Illness and social relations may be closely inter-related, for an illness may bring about a social or economic maladjustment, or a social and economic maladjustment may bring about illness. The maintenance of individual and community health is the responsibility, not only of the medical profession, but also of the lay public. Parents, teachers, nurses, health visitors and social workers have their own contributions to make and responsibilities to assume in maintaining and improving individual and community health. The better they are equipped with knowledge, the more efficient will be the service that they can render. The social worker, when he or she is properly supplied with medical information, can render practical assistance in promoting the cure and prevention of disease, *e.g.*, as regards assistance to the patient; assistance to the doctor, hospital or health agency; and contributions towards educational movements and legislation in the interests of public health. Even in treatment of diseases, one has often to adjust the physical conditions of the environment to the needs of the patient.

In catering for the above adjustments, the authors have been singularly successful. The various subjects and diseases with social implications have been dealt with briefly but lucidly. The initial chapters deal with cardiovascular diseases, rheumatic fever, diseases of the respiratory system, allergic diseases, syphilis, tuberculosis, etc. The pediatric section, including feeding and nutrition, has been placed next. Surgery of conditions with a medico-social significance has also been dealt with. The more specialized fields of gynaecology, orthopaedics, obstetrics and the like follow next. A useful bibliography, exercises in anatomy and physiology, and an index conclude the book.

With the growth of organized social service, the book is likely to be useful to all workers who desire to render or organize more intensive and better service for the community. The printing, paper, illustrations and the arrangement of materials are good.

A. C. U.

CLASSIFIED AND ANNOTATED BIBLIOGRAPHY OF SIR WILLIAM OSLER'S PUBLICATIONS. (BASED ON THE CHRONOLOGICAL BIBLIOGRAPHY BY MINNIE WRIGHT BLOGG.)—Edited by M. E. Abbott, B.A., M.D., LL.D. (McGill). Second Edition. 1939. The Medical Museum, McGill University, Montreal, Canada. Pp. xiii plus 163. Price, \$2.25

SIR WILLIAM OSLER was not only a great physician, but a deep thinker and a writer with great powers of expression. His writings covered a period of exactly fifty years, but his books will be read and his influence felt for many centuries.

This bibliography gives one some idea of the untiring activity of his very full life. It is an essential addition to the library of anyone who has made a study of Osler's writings.

THE GENUINE WORKS OF HIPPOCRATES. TRANSLATED FROM THE GREEK.—By F. Adams, LL.D. 1939. Baillière, Tindall and Cox, London. Pp. viii plus 384. Price, 13s. 6d.

No ancient writer is referred to more frequently than Hippocrates. This is not difficult to understand. It is not so much that we overlook what seem to us as naïvetés and puerilities for the sake of his flashes of intuition, but that his whole outlook is so very much the same as ours, or to put it more fairly, after wandering about in the dark for over two thousand years we have come back to his point of view. Take for example the Hippocratic oath; one cannot criticize a single sentence in it. Then again, his method of presenting a case is almost exactly the method that the student of to-day is taught: he gives the age, the history, and the habits of the patient, he describes the onset, and then gives the outstanding events day by day. When he comes to the cause of death, or recovery, his remarks are reminiscent of the average death certificate of to-day; from an ætiological point of view, it is not illuminating to attribute death to 'profuse sweating' and 'convulsions'. Though he does sometimes go a little further back to find the cause of the trouble, as for example in the case of the young man who died of what might have been severe bacillary dysentery; his death is attributed to 'unreasonable practices' which consisted in 'fatigue, labour, and running out of season'. This is probably about as near to the truth—if we know it to-day—as anyone would have got, up to about 50 years ago.

These selections from the writings of Hippocrates were translated by Francis Adams, a Scottish surgeon, about a hundred years ago at the instance of the Sydenham Society. They were published in 1849 with profuse notes: the latter have been omitted in order to present 'a continuous and connected picture of medicine in the Golden Age of Greece'. This much has been gained, but the wonderful opportunity of a three-point comparison has been lost by the omission of these notes.

A volume of the works of Hippocrates should be in the library of every thinking physician and surgeon, and this edition is a very pleasing one.

AIDS TO FEVER NURSING.—By J. M. Watson, S.R.N., S.R.F.N., D.N. (Lond.). 1939. Baillière, Tindall and Cox, London. Pp. xii plus 284. Illustrated. Price, 3s. 6d.

THIS book dealing with fever nursing is one of a series of handbooks that are being published to cover all the subjects included in the examination syllabus of the general nursing council.

The author has succeeded in presenting the outline of the whole field of modern fever nursing in this small volume. The sections are well written and contain in detail the practical nursing procedures required in the modern treatment of the various infectious diseases.

The book will prove useful to those for whom it is meant.

Abstracts from Reports

ANNUAL PUBLIC HEALTH REPORT OF THE PROVINCE OF ORISSA FOR THE YEAR 1937. BY LIEUT.-COLONEL VERGHESE, I.M.S., DIRECTOR OF HEALTH AND INSPECTOR-GENERAL OF PRISONS

STATE OF PUBLIC HEALTH IN THE PROVINCE AND HISTORY OF THE CHIEF DISEASES—EPIDEMIOLOGY

Incidence of chief diseases.—The statement below shows the ratios per 1,000 of population under the chief heads of mortality in 1937:—

	Urban	Rural	Combined
Cholera	0.4	0.7	0.7
Smallpox	0.1	0.3	0.3
Fevers	7.7	15.5	15.2
Dysentery and diarrhoea	3.1	2.5	2.5
Respiratory diseases ..	1.7	0.7	0.7
Injuries	0.4	0.4	0.4
All other causes	8.0	8.8	8.8

The death rate increased from 27.8 in 1936 to 28.6 per mille of population in 1937. The increase in the number of deaths was chiefly due to large number of deaths from fever under which the death rate of 15.2 was reported as against 14.0 in the preceding year.

The highest death rate 15.2 was recorded from fevers but in the absence of any arrangements to report correct diagnosis it is not possible to say what percentage of deaths under fevers is definitely due to malaria.

The urban death rates from cholera, smallpox and fevers were lower than those of the rural areas. This is ascribed to better standard of sanitation in the municipal towns but the mortality rate from dysentery and diarrhoea and respiratory diseases still remains higher in the urban areas. The high mortality rate from dysentery and diarrhoea in the urban areas of this province is mainly due to the bad state of water-supply.

No case of plague was reported in this province during the year under report. Particular care was, however, taken to prevent this infection getting through the port of Gopalpur into this province through immigrants returning from plague-infected ports, such as Rangoon.

Maternity and child-welfare.—As the new province of Orissa could not form a maternity and child-welfare society of its own the Bihar maternity and child-welfare society continued to work through its managing committee in so far as the North Orissa districts were concerned. No share of the invested capital of the Bihar and Orissa society was received by Orissa as it was held that the invested capital of Rs. 20,000 was made up only of donations from Bihar. The local centres in Orissa are financed from the annual grant made by the Provincial Government and by contributions made by the local bodies and donations collected locally.

There were five maternity and child-welfare centres, *viz.*, one at Cuttack, one in Balasore, one in Sambalpur and two in Ganjam district, at Berhampur and Parlakimedi. Each centre is managed by a local committee.

School hygiene and medical inspection of school children.—There is one school medical officer of the Provincial Public Health Service, with the necessary public health qualification and one assistant school medical officer of sub-assistant surgeon class for this province. These officers inspect all the high English schools and most of the middle English schools of the province. The boys in the middle English and the middle vernacular schools in the rural areas are

examined by the district board health staff and district board dispensary doctors. No examination of school children in primary schools is done as the number of such schools is too large for the existing Government or district board staff.

ANNUAL REPORT ON THE WORKING OF THE RANCHI INDIAN MENTAL HOSPITAL, KANKE, IN BIHAR, FOR THE YEAR 1937. BY LIEUT.-COLONEL J. E. DHUNJIBHOY, M.B., B.S., F.C.P.S., I.M.S., SUPERINTENDENT

As in the past, the majority of so-called 'new admissions' during 1936 were old chronic mental patients with marked debility and other physical ailments who were kept at home for years, and were sent for treatment when they became unmanageable at home and proved dangerous to themselves and others. The recovery and the improved rates during the year under report should be considered extremely satisfactory considering the above state of affairs.

More than 50 per cent of the deaths occurred amongst old chronic demented who had been in the hospital for 20 years or more. Eight deaths that took place within a year of their admission were amongst those patients who were admitted in the hospital during the year under review with marked physical ailments.

Health of patients.—The general health of patients was good throughout the year under report and there were no outbreaks of an epidemic nature.

The following were the main types of physical disorders treated in the infirmaries during the year under report:—

Amoebic and bacillary dysentery, malaria, diseases of the connective tissues, skin diseases, debility, injuries, diseases of the digestive system, influenza, tuberculosis of the lungs, diseases of the respiratory system, ulcers and inflammations, primary and secondary anaemia, worms, specially ankylostoma and round worms.

I am glad to be able to record that the Government were pleased during the year under report to sanction my scheme (as stated in the previous year's report) for the conversion of one of the existing spare occupational therapy buildings in the female section at a nominal cost into a children's ward which will accommodate certified defective children. It is hoped that the work will now be completed without any further delay.

MENTAL DEFECTIVES OF INDIA

It will be presumably permissible to mention here that there exists no state or social controls for the mental defectives in India. No reliable statistics are available as to the number of such defectives in India but if such figures were obtainable they would indeed be very large. In this complex system of social relations what place can be found for the subnormal individual, who starts life, not only with a poor mental endowment, but with temperamental difficulties he can neither understand nor control?

He must be protected from dangers and others must be safeguarded from the results of his social conduct. While every civilized country has made and is making efforts to provide schools and institutions for some at least of its defectives, almost nothing has been done in India for its unfortunate defectives. India's defectives are at large and are allowed to do what they like and in absence of proper segregation and control by the State they thus perpetuate the mental defective race in India. The problem, I admit, is very vast, and would appear to be unsurmountable from the financial point of view, but, as India is now making all efforts at onward march of civilization it should also make a start in this direction, no matter how humble and ineffective it might appear. The Report of the British Royal Commission on feeble-mindedness of England states that 40 per cent of the juvenile offenders were feeble-minded and 20 per cent of the prison population of England were feeble-minded. If we were to make

a similar investigation of our jails in India our figure would probably treble that of England.

Since the true indictment of mental deficiency as a social evil of tremendous proportions has been found by Commissions appointed by civilized countries like England, America and Germany, we in India should take advantage of their findings and should start reform in this direction without any further delay. As the problem is vast and no statistics are available to judge the magnitude of the problem, I suggest that all Provincial Governments in India should make every effort for a start even on a small scale in this direction on the lines suggested herein:—

(1) To ascertain as far as possible the approximate number of all mental defectives in each Province.

(2) To sort out all grades of defective children from existing schools by the help of the school medical officers and establish special schools for them.

(3) To establish a large Central Provincial Institution for the training and segregation of defectives with anti-social propensities including housing of criminal defectives of all ages.

(4) Provision of adequate facilities for the training of the whole personnel required for this work such as psychiatrists, psychologists, nurses, social workers and teachers.

(5) Education of public opinion to a recognition of the racial dangers underlying the unchecked increase of mental deficiency.

(6) Eugenic sterilization of all known adult defectives of both sexes.

Life segregation in large central provincial institutions and sterilization hold out the greatest hope of most immediate and effective results. Sterilization is adopted by a number of civilized countries all over the world and it is a means of ridding the race of its defective germ plasma. Sterilization must supplement segregation as a measure of control to prevent procreation because no state, however rich, can ever afford institutional facilities for all their defectives. Sterilization therefore relieves the state of a heavy financial burden.

Drugs—(a) *Cardiazol*.—We continued our experiment with cardiazol throughout the year under report. During 1937 I tried this treatment on 42 cases of schizophrenia (31 males and 11 females). The sub-joined table shows the results.

Number of cases	Types of schizophrenics	Full remission	Improved	Stationary
15	Katatonic ..	7	4	4
17	Hebephrenic ..	5	9	3
8	Dementia paranoïdes.	1	2	5
2	Simple dementia	2

The thirteen cases which attained full remissions were subsequently discharged by the Board of Visitors of the hospital as fully recovered, three of them wrote to me that they had re-joined their services and the remaining 10 patients have so far maintained the improvement.

(b) *Photodyne*.—During the year under review six patients with marked endogenous depressions were treated with this drug but the results were not very encouraging. Only one female patient showed some improvement. I also tried this drug in my private practice but there also the results were not encouraging.

(c) *Benzedrine*.—This drug is found very useful in cases of mild depression either of exogenous or endogenous origin.

(d) *Narco-analysis*.—We tried narco-analysis with sodium evipan but the results were poor and treatment has not come up to our expectation.

(e) *Paraldehyde*.—This drug is much too universally used as a hypnotic and this is no doubt due to its

cheapness and the fact that it has no depressing effect on the heart.

Use of paraldehyde per rectum and by intramuscular injection.—Paraldehyde is one of the most useful sleep-producing drugs at our disposal and in acute cases of maniacal excitement it acts like a charm in some cases when given deep intramuscularly in the gluteal region for 12 consecutive days at a rate of one drachm per day. Similarly, paraldehyde can be used as 'prolonged continuous narcosis' in highly intractable maniacal cases when given per rectum. The dose in such cases should be one drachm per stone of patient's total body-weight. This method is largely used in general practice all over the world by surgeons to remove pre-operative fright in nervous patients before undergoing major operations. One of our highly excited patients, who showed no signs of improvement or abatement of excitement in spite of vigorous treatment by all the known hypnotics and sedatives at our command, showed marked improvement by this method.

Sulfosin therapy.—This very useful therapy was given to 86 patients during the year under report and the results were as follows:—

Recovered	Improved	Stationary
11	28	47

SERUM INTOLERANCE IN FAMILIES

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—Does serum intolerance run in families? This question has occurred to me in dealing with an extremely severe delayed reaction in a lady some time back.

On discussion, it came out that a few years back an uncle of the lady developed severe reactions after receiving serum. I have not come across any authoritative finding proving or disproving the contention. Both the cases got serum for the first time in life and I am loth to give any serum to any other member of the family, even if indicated.

Yours, etc.,

N. Z. KHAN, M.B.

35, AMIR ALI AVENUE,
CALCUTTA,
2nd September, 1939.

[Note.—The accepted opinion is that specific hypersensitiveness is not transmitted hereditarily, but that a general increased sensitivity often runs in families.—EDITOR, I. M. G.]

A CURE FOR SCORPION STINGS

To the Editor, THE INDIAN MEDICAL GAZETTE

SIR,—The medical profession is in search of an effective drug for the successful relief of scorpion sting from a long time. With this object the Kasauli Institute and other medical research institutions are carrying on experiments with herbal drugs, mineral salts and local anaesthetics for relieving the most excruciating and agonizing pain caused by the scorpion sting, without any success. I lately happened to try the application of coarsely-pounded fresh leaves of *Acalifus indica*. Its vernacular names being—*Kuppa mani* (Tamil), *Kuppi chettu* (Telugu), *Kuppi-ka-jhad* (Hindi) which grows ubiquitous on the manure heaps (midden-stead) in many parts of India. It can be procured very easily and grown in flower pots in every house and can thus be made available for any emergency use without much trouble or tending. This when applied to the part stung completely allays the pain and cures the condition within two or three minutes of its application. In its action it is prompt

The Report of the British Royal Commission on feeble-mindedness of England states that 40 per cent of the juvenile offenders were feeble-minded and 20 per cent of the prison population of England were feeble-minded. If we were to make

Lieutenant-Colonel A. S. Garewal, Superintendent, Central Jail, Jubbulpore, transferred to Nagpur as Superintendent, Central Jail, Nagpur, from 18th September, 1939.

On having been recalled from leave, Lieutenant-Colonel W. Ross-Stewart, c.i.e., resumed charge of the Office of Civil Surgeon, Lahore, on the afternoon of the 30th September, 1939, relieving Major G. F. Taylor, Professor of Clinical Medicine, K. E. Medical College, Lahore, of the additional charge.

On reversion from foreign service under the Association of the Pasteur Institute of India, Kasauli, Lieutenant-Colonel W. J. Webster, m.c., is appointed as Assistant Director, Central Research Institute, Kasauli, with effect from the forenoon of the 1st October, 1939.

Lieutenant-Colonel B. P. Baliga, made over charge of the Dum Dum Central Jail to Major S. Annaswami, on the forenoon of the 1st October, 1939.

Lieutenant-Colonel K. S. Thakur, Officiating Surgeon-General with the Government of Bengal, on relief, is appointed to be Civil Surgeon, 24-Parganas, *vice* Lieutenant-Colonel S. Nag.

Major D. P. Lambert reverted to military duty from civil, Meerut, and joined C. I. M. H., Wana, on 9th August, 1939.

Major S. A. O'Connor, an Agency Surgeon, is employed to officiate as Chief Medical Officer and Inspector-General of Prisons in Baluchistan, with effect from the afternoon of the 23rd August, 1939.

Major W. T. Taylor, on return from leave, took over charge of the Medical Store Depot, Madras, on the forenoon of the 4th September, 1939, relieving Captain (Sr. Assistant Surgeon) D. M. Frost, of the additional duties entrusted to his charge.

Major A. N. Chopra, under training at the Central Jail, Jubbulpore, appointed as Superintendent, Central Jail, Jubbulpore, from 17th September, 1939.

Major G. B. W. Fisher, Civil Surgeon, Jalpaiguri, is appointed to be the Resident Medical Officer, Eden Hospital, Calcutta, *vice* Dr. Anil Chandra Bhowmic.

Major S. Annaswami made over charge of the Midnapore Central Jail to Captain J. White, on the forenoon of the 25th September, 1939.

Major B. Chaudhuri, on the expiry of his leave, is posted to the Presidency Jail on training for a period of 1 month from the 29th September, 1939, and thereafter is appointed to act as Superintendent of the Midnapore Central Jail, with effect from the 29th October, 1939, or any subsequent date of joining.

Captain G. W. Millar was attached to the Port Health Department, Bombay, as a leave reserve officer under the Central Government, from the 21st July, 1939, to the forenoon of the 31st July, 1939, and is appointed to officiate as Port Health Officer, Bombay, from the afternoon of the 31st July, 1939, until further orders.

Captain M. S. Zan, in military employment in Burma, was transferred to civil employment in Burma, with effect from the 4th August, 1939.

Captain R. I. Reid to be Deputy Assistant Director-General (Medical Stores), Lahore. Dated 15th August, 1939.

Captain W. S. Morgan, i.m.s., is appointed to officiate as an Agency Surgeon and posted as the Medical Officer in charge of the Crown Representative's Police Force Hospital, Neemuch, with effect from the forenoon of the 20th August, 1939.

Captain M. Ata-Ullah to be Eye Specialist, Meerut District, with effect from the 9th August, 1939.

Captain E. C. Hicks to be X-Ray Specialist, Bannu. Dated 28th August, 1939.

Captain F. V. Stonham, Officer on Special Duty at the Mayo Hospital, Lahore, was posted as Civil Surgeon, Gujrat, with effect from the 11th September, 1939.

Captain J. White, Civil Surgeon, Midnapore, is appointed to act as Superintendent of the Midnapore Central Jail, in addition to his own duties, with effect from the 15th September, 1939, or from any subsequent

date on which Major S. Annaswami, now Superintendent of that Jail, proceeds to take charge of the Dum Dum Central Jail.

This cancels previous notification.

Captain E. H. Lossing, Civil Surgeon, Hooghly, is appointed to be Civil Surgeon, Jalpaiguri, *vice* Major G. B. W. Fisher.

Captain R. L. Haviland-Minchin, Assistant Director, Central Research Institute, Kasauli, is appointed a leave reserve officer against the Central Indian Medical Service cadre, with effect from the forenoon of the 1st October, 1939.

Lieutenant (on probation) H. Rees is restored to the establishment, 1st May, 1939, with seniority 1st May, 1938.

LEAVE

Lieutenant-Colonel G. Covell, c.i.e., Director, Malaria Institute of India, on foreign service under the Indian Research Fund Association, is granted leave for 1 month and 29 days on average pay, and in continuation, leave for 17 days on half-average pay, with effect from the 5th August, 1939. His services are replaced at the disposal of the Director-General, Indian Medical Service, with effect from that date.

Lieutenant-Colonel W. P. Hogg, m.c., Chief Medical Officer and Inspector-General of Prisons in Baluchistan, is granted leave for 3 months and 10 days, with effect from the afternoon of the 23rd August, 1939.

Major J. A. W. Edden, Chief Medical Officer, Delhi, was granted leave on average pay for 1 month and 22 days, with effect from the 26th June to the 16th July, 1939.

PROMOTIONS

Lieutenant-Colonels to be Colonels

T. C. Boyd. Dated 9th August, 1939, with seniority from 1st February, 1931.

R. Sweet, d.s.o. Dated 21st June, 1939, with seniority from 23rd July, 1935.

A. C. Macrae. Dated 21st June, 1939, with seniority from 23rd July, 1935.

The undermentioned I. M. S. Officers are advanced to the List of Special Selected Lieutenant-Colonels:—
Lieutenant-Colonel K. S. Thakur. Dated 9th August, 1939.

Lieutenant-Colonel M. A. Nicholson. Dated 17th August, 1939.

Captains to be Majors

P. V. Bamford. Dated 15th July, 1939.

K. Jilani. Dated 26th July, 1939.

S. M. Kharegat. Dated 15th July, 1939.

D. H. Waldron. Dated 6th August, 1939.

C. H. Dhala. Dated 8th August, 1939.

S. Narain. Dated 25th August, 1939.

To be Captain (on probation)

H. B. Wright. Dated 7th June, 1939, with seniority as Lieutenant from 21st June, 1933.

(Temporary Commission)

Lieutenant to be Captain

Thein Maung. Dated 29th March, 1939.

Lieutenant (on probation) to be Captain (on probation)

J. A. Anderson. Dated 1st September, 1939.

RETIREMENTS

Colonel D. C. V. FitzGerald, m.c., K.H.P. Dated 22nd October, 1939.

Lieutenant-Colonel R. Clifford, d.s.o., m.c. Dated 1st August, 1939.

Captain J. W. Richmond. Dated 26th July, 1939.

RELINQUISHMENTS

The undermentioned officers relinquish their probationary appointments:—

Captain (on probation) P. B. Cussack, 10th February, 1939.

Captain (on probation) N. P. Woodgate-Jones, 10th July, 1939.

Captain (on probation) G. C. A. Jackson relinquishes his probationary appointment on account of ill health, 14th July, 1939.

Notes

A CATALOGUE (1939) OF THE BRITISH DRUG HOUSE FOR MEDICAL PRODUCTS

We have just received the British Drug House's new (1939) catalogue of medical products.

It is a well-arranged catalogue with the names printed in red. This not only facilitates easy reference but adds to the appearance of this neat little book.

This British firm have a wide range of products and, at a time when a number of foreign products are no longer available, it should be particularly useful.

Copies will be supplied to readers who apply to The British Drug Houses Ltd. (Incorporated in England), Imperial Chemical House, Ballard Estate, Bombay.

KAPSEALS DILANTIN

A new drug to control epileptic seizures

DILANTIN or 'Epanutin', the name by which it is known in England, was made available to the medical profession by Parke, Davis and Company, following clinical studies in epilepsy reported at the 1938 annual convention of the American Medical Association held in San Francisco. Drs. H. Houston Merritt and Tracy J. Putnam of Harvard Medical School reported on 200 cases of epilepsy treated with Sodium Diphenyl Hydantoinate (Dilantin). These two workers have more recently reported the results of two years' treatment: *Proc. Amer. Neurol. Ass.*, June 1939.

Evaluation of sodium diphenyl hydantoinate was made on patients who had not been controlled by accepted therapeutic measures such as phenobarbital, bromides, ketogenic diet, and fluid restriction. A total of 142 patients who had been under treatment with sodium diphenyl hydantoinate for periods ranging from two to eleven months formed the main part of the report. In this group *grand mal* attacks were prevented in 58 per cent, and greatly decreased in frequency in an additional 27 per cent. Seizures of the *petit mal* type were prevented in 35 per cent of patients treated, and greatly decreased in number in an additional 49 per cent. Reports of Dilantin since its introduction to the profession in Europe and America have fully confirmed the findings of Merritt

'MEAD' ARM SLING

THIS adjustable arm sling, which has been approved by the medical profession, has several advantages over any other sling:—It can be used for either arm; the

weight is carried by the shoulder and not by the neck; it is adjusted easily by means of a non-slipping buckle; and being made of strong gingham, it is light and washable.

A smaller size, suitable for children, is also available. It can be obtained from Messrs. C. J. Hewlett and Son, Limited, 35-42, Charlotte Road, London, E.C.2.

FURTHER OBSERVATIONS ON PROTAMINE ZINC INSULIN IN CLINICAL DIABETES

By J. P. BOSE, M.B., F.C.S. (Lond.)

(Diabetes Research Department, School of Tropical Medicine, Calcutta)

ONE of the main difficulties that the average practitioner encounters regarding the use of insulin in clinical diabetes is the adjustment of the proper dosage, on account of insulin having no fixed or standard dosage of its own. The result is that, if proper dosages are not employed, there is either little or no reduction in the blood-sugar level if the dose is too small, or there is dangerous oscillation in the blood-sugar level, if the dose is too large. The new insulin compound—*protamine zinc insulin*—has simplified this problem to a certain extent, not only from the point of view of the doctor but also of the patient as well, though those unused to this new drug still betray some amount of pessimism regarding its use.

Before discussing the merits and demerits of protamine zinc insulin, as compared to the ordinary insulin, a broad discussion of the question of the insulin requirements of diabetic patients of various grades of severity will be helpful. We know that in a normal healthy individual there is a regulated and almost continuous secretion of insulin from the normal pancreas. This is known as the 'basal' secretion of insulin; it is augmented at times according to the physiological needs of the organism, as, for instance, after meals. By this procedure the sugar metabolism of the system is controlled throughout the day and the blood-sugar is maintained within normal limits.

In diabetes, however, the picture is quite different. The primary defect in diabetes lies in the fact that there is lack of secretion of insulin, even under basal conditions, and on the degree of this lack of secretion depends whether the case is mild, moderate, or severe. The power of the normal healthy pancreas of secreting the necessary extra amount of insulin under hyperglycæmic stimulation (as after a rich carbohydrate meal) is quite efficient, and thus the excess of sugar is removed from the blood stream and the blood-sugar level brought down to normal. In diabetic subjects, however, this power of requisitioning for the necessary extra amount of the hormone after a carbohydrate meal, is either deficient in varying degrees or almost absent according to the severity of the disease, and this naturally depends on the extent of damage which the pancreas has undergone. In the mild or

moderate types, where the organ can still produce sufficient endogenous hormone (though the supply is slow) it is able to control the blood-sugar level provided the patient's diet is lowered sufficiently, so that the amount of endogenous insulin produced is able to cope with it. In the severe cases, however, where the insulin-secreting cells of the pancreas are damaged to such an extent that they can produce very little of the hormone, the reduction of the blood-sugar level is almost negligible.

Thus, it appears that the insulin requirement of the diabetic individual depends on several factors. Apart from other abnormal factors such as infections, acidosis, etc., it appears to depend mainly on his power of requisitioning for the extra amount of endogenous insulin under the stress of hyperglycæmic stimulation of the pancreas (as after meals). A rough idea regarding this may be obtained by putting the patient on a minimum or the basal diet. If after putting the patient on the 'basal diet', the glycosuria persists and the blood-sugar remains high, the insulin requirement would then depend roughly on the amount of glucose which the patient cannot utilize in the system (i.e., the total amount excreted in the urine in 24 hours). In a milder case this will naturally be small and in a severe case high.

In the severe cases of diabetes, where the insulin requirement is high, to prevent sudden and dangerous oscillations of the blood-sugar level consequent on the big dosages, and also to keep effective control over the blood-sugar throughout 24 hours, the big single dose of insulin has to be divided and given in two or more smaller doses. This is a great disadvantage especially from the point of view of nocturnal hyperglycæmia which almost invariably happens in severe diabetes, particularly of the juvenile type. From a study of a large number of these cases, it appears to the writer that there is a tendency for the blood-sugar to rise during the early hours of the morning, i.e., between 2 and 4 in the morning. Before the advent of the new compound, protamine zinc insulin, the occurrence of this nocturnal or early morning hyperglycæmia could only be controlled by giving the patient one injection at retiring time, say at 9 p.m., and one in the early morning, say between 2 and 3 a.m.; but such a procedure, apart from the great discomfort, both to the patient and the doctor, was not always free from the danger of an occasional overdose. Since the discovery of protamine zinc insulin, however, this handicap has been removed to a great extent.

The problem of finding the insulin requirement of a given diabetic has by no means been entirely solved with the advent of the protamine zinc insulin. Owing to such disadvantages as the slowness and the uncertain continuity of its action, its summation and cumulative effect,

lack of uniformity of its action and also owing to the varying rate of absorption from the tissues, the individual requirement of protamine zinc insulin cannot be predicted with precision; but nevertheless there is no denying the fact that the use of protamine zinc insulin has several distinct advantages over the ordinary insulin. Owing to its slow, persistent and long-continued action (simulating the secretion of insulin from normal pancreas) it has helped to keep a much better and more effective control over the blood-sugar level for a long period, often without a repetition of the injection; the nocturnal hyperglycæmia and the tendency to ketosis is thus controlled in an effective way. Then again the carbohydrate can be spread out more evenly over all the meals instead of being mainly confined to those following the insulin injections as has hitherto been the practice. If the dose of protamine zinc insulin is carefully regulated, there is less likelihood of a sudden reduction of blood-sugar, and thus the risks of hypoglycæmia during sleep is obviated.

The question now arises as to how the 'basal' dose of protamine zinc insulin has to be fixed in a given case. As has been stated before, there are no hard and fast rules regarding this; one has to find a dose, which should continue its action for 24 hours, tend to bring the 'fasting' level of blood-sugar within normal limits and yet cause no hypoglycæmia during the night. This is usually possible in most cases by careful adjustment of the dose during the first four or five days, checking it by estimation of the early morning blood-sugar (about 6 a.m.), or, where this is not possible, by examination of at least two specimens of urine, *viz*, one 2 to 3 hours after the night meal and another in the early morning. If the early morning specimen continues to show sugar, it usually indicates that the blood-sugar was high and the dose of insulin has to be increased. If, on the other hand, the specimen 2 to 3 hours after dinner is sugar-free, it usually indicates that the dose of protamine zinc insulin is enough to control the hyperglycæmia and the dose has usually to be decreased to prevent sudden hyperglycæmia during sleep. If, however, the specimen after dinner contains sugar but the early morning specimen is sugar-free, it is wiser to ascertain the level of the early morning blood-sugar before an attempt is made to regulate the dose of protamine zinc insulin.

A difficult problem which sometimes confronts the physician is that some of the severe cases of diabetes receiving big doses of protamine zinc insulin have severe hypoglycæmic reactions during the night and yet show an early morning hyperglycæmia of a fair or even marked degree (table I). The author has had several cases of this type though fortunately such cases are not usually met with.

The results of a single dose of 52 units of protamine zinc insulin on a moderately severe

case of diabetes of the above type are given below.

TABLE I

Patient—S. A.

Date	27/7/39					28/7/39	
	6 a.m.	10 a.m.	2 p.m.	6 p.m.	10 p.m.	2 a.m.	6 a.m.
Blood-sugar.	266	260	220	190	86	160	240

At first the patient was tried with smaller doses of protamine zinc insulin, but no appreciable reduction of either the glycosuria or the morning hyperglycæmia having been obtained the dose was gradually increased to 52 units. It was then noticed that though the patient began to get mild or moderate hypoglycæmic attacks during the night, yet there was little change in the early morning hyperglycæmia. The results are graphically represented below.

CHART 1

It would appear from the chart that there is a slow fall of blood-sugar during the first four hours after the injection of protamine zinc insulin, after which the blood-sugar continues to fall steadily and rather rapidly, so that it becomes quite low 16 hours after the injection, causing symptoms of hypoglycæmia. The total reduction of blood-sugar from the initial level is thus over 60 per cent within 16 hours. The action of protamine zinc insulin thereafter appears to wear off and the blood-sugar begins to rise steadily again. The net result is that the state of the early morning hyperglycæmia on the next day attains almost the same level as that of the previous day, the difference being only a reduction of 10 per cent even after such a big dose of protamine zinc insulin.

Having got this rather peculiar result we tried the same dose on the patient for three successive days to make sure whether the state of affairs would ultimately improve, but it did not. It was then thought that the sustained fall of blood-sugar causing hypoglycæmia was due to the big single dose of protamine zinc insulin employed and that it worked for 16 hours only, after which its action entirely ceased.

To find out whether this unsatisfactory state of affairs could be improved by reducing the dose of protamine zinc insulin but at the same time adding to it a small dose of soluble insulin (keeping the total dose almost the same), a dose of 20 units of ordinary insulin

plus 30 units of protamine zinc insulin was tried on the same patient, and was given in one injection by drawing the two solutions into the same syringe. It should be noted here incidentally that the soluble insulin should be drawn first, because being on the acid side it does not matter if a trace of it enters the buffered protamine zinc insulin.

It has been clinically observed that the intensity and the duration of action of protamine zinc insulin depends on the dosage given. If the dose given is small (within certain limits), the action is slow but prolonged. In a previous paper (Bose, 1938) it has been shown that by employing a single dose of 30 units of protamine zinc insulin no change in the blood-sugar was observed until 3 to 4 hours after the injection, when it began to fall. The rate of fall of blood-sugar thereafter, though slow, continued for about 24 hours. In the present instance, however, it has been observed that with a bigger single dose of protamine zinc insulin employed, the action became quicker and more intense but much less prolonged, so that the action appeared to wear off after 16 hours. The idea of using a smaller dosage of protamine zinc insulin and supplementing it with a small dose of ordinary insulin, as in the present case, is that the soluble insulin will act quickly and control the excessive hyperglycæmia to a certain extent during the first 4 to 6 hours, after which its action will decline or cease altogether. The smaller dose of the protamine zinc insulin, on account of its slower and prolonged action, will thereafter continue to effect the reduction of blood-sugar. The severe and the prolonged fall of blood-sugar consequent on the big single dose of protamine zinc insulin will thereby be eliminated.

The table below shows the action of 20 units of ordinary insulin plus 30 units of protamine zinc insulin on the same patient. The injection was given at 6 a.m. daily for three successive days and the blood-sugar estimated every 4 hours for 3 days running.

TABLE II

Patient—S. A.

Date	Time 2 a.m.	6 a.m.	10 a.m.	2 p.m.	6 p.m.	10 p.m.
1/8	..	240	160	133	150	122
2/8	150	180	120	140	134	110
3/8	134	150	98	126	134	124
4/8	130	136

The above results are represented in chart 2.

It appears from the above table that the control of the blood-sugar is much more effective when a combined dose of 20 units of ordinary insulin plus 30 units of protamine zinc insulin is given than when a single big dose of 52 units of protamine zinc insulin is given (chart 2).

It also appears that there is a substantial improvement in the level of the early morning hyperglycæmia (6 a.m.) from day to day without any hypoglycæmia during the night. The

CHART 2

reduction of the early morning hyperglycæmia was 25 per cent after 24 hours, 37.5 per cent after 48 hours and 43.4 per cent after 72 hours.

There was also a marked general improvement in the patient's condition. When the early morning blood-sugar came down to 0.136 per cent on the 4th day, the ordinary insulin was omitted and only 20 units of protamine zinc insulin were given till the blood-sugar came down within normal limits.

Summary and conclusions

(1) The insulin requirement of diabetic individuals is discussed in a general way.

(2) The advantages of the protamine zinc insulin over the ordinary insulin is discussed. Most cases of diabetes, mild and moderate, can be kept under control by a single dose of protamine zinc insulin instead of repeated doses of ordinary insulin. It has been observed, however, that a few cases of diabetes of moderate grade of severity cannot be satisfactorily controlled by a single dose of protamine zinc insulin. In this group, satisfactory control of the blood-sugar is not usually obtained even though the dose is raised to a very high level, because it has been observed that the effect of administering such a big single dose of protamine zinc insulin was that the patient has hypoglycæmic attacks during the night and yet shows a fair amount of early morning hyperglycæmia.

(3) Better results have been obtained in cases of this group if, instead of a single big dose of protamine zinc insulin, a small dose is given supplemented by a dose of ordinary insulin and the combination given in one injection. An instance of the above is given.

INTRAVENOUS ANÆSTHESIA WITH PENTOTHAL SODIUM

By G. R. RAWLINGS, M.B., B.Chir. (Cantab.),
D.A. (Eng.)
Calcutta

Now that further supplies of evipan sodium will be unobtainable in this country there will be a demand for a satisfactory substitute. Pentothal sodium can fulfil this need, and, in point of fact, is a vastly superior anæsthetic agent. For those anæsthetists familiar with the use of evipan a comparison between the two drugs may be useful, coupled with a description of the use and action of pentothal.

Pentothal sodium was introduced by the Abbott Laboratories in America about five years ago, and the first reports of extensive clinical trial appeared in 1935 (Lundy). In England the first report was published a few months later, early in 1936 (Jarman). Since this time, in my experience, anæsthetists who have once used pentothal have almost entirely discarded evipan.

Pentothal sodium, the sodium salt of ethyl (1-methyl butyl) thiobarbiturate, is a yellow powder readily soluble in water. It is somewhat more rapidly detoxicated and excreted than evipan. The sulphur contained in the thiobarbiturates seems to hasten their destruction in the body. When first introduced, the drug was given in a 10 per cent solution, but it has been found that a 5 per cent solution is more satisfactory, as a finer control of dosage is obtained. This also lessens the risk of tissue damage if the solution is inadvertently injected extravascularly.

During surgical anæsthesia with pentothal the skeletal reflexes are abolished, together with the corneal reflex. The pharyngeal reflex remains unaltered. Vasodilatation usually occurs, and in some cases marked conjunctival injection is seen. There is frequently a slight fall in blood pressure, but no great change in the pulse is noticeable. Pentothal, like all barbiturates, is a respiratory depressant with no direct action on the heart. Respiratory depression is definitely greater than with evipan, but this is the only important feature in which pentothal compares unfavourably with it. The ability of pentothal to cause profound muscular relaxation is one of its outstanding characteristics, and in this respect is far superior to evipan.

Administration.—Pentothal sodium is put up in ampoules containing 0.5 gramme and 1 gramme and these are dissolved in 10 cubic centimetres and 20 cubic centimetres of distilled water, respectively. The solution is injected intravenously and the patient can be made to count during the induction period, although, personally, I prefer to tell the patient to look at me and to watch his eye movements. The first 2 or 3 cubic centimetres should be given in about ten seconds and then a pause should be

made. The patient is usually asleep within thirty seconds. Muscular relaxation does not develop for a minute or so after unconsciousness, so the full effect should be awaited before the injection is continued. A 'one-shot' technique should *never* be employed except for the shortest operations lasting a minute or two, owing to the powerful depressant effect on respiration coupled with the rapid excretion. For any longer operations the anæsthetic should be given in divided doses. The needle is kept in the vein and 0.5 to 1 cubic centimetre is given at intervals as the operation progresses. The amount given is governed by the reaction of the patient. Depth of anæsthesia is gauged by the effect on respiration. The rate is little altered, but the excursion is reduced as anæsthesia deepens. Lightening of anæsthesia is indicated by small movements, diminished relaxation, and slight phonation, etc. Great care must be taken to see that the jaw is supported, as, on account of the intense muscular relaxation, it is very likely to fall back and obstruct the airway. A completely free airway is essential as respiration is already depressed and further embarrassment is likely to cause cyanosis. In some cases the insertion of an artificial airway is of great service. The preliminary injection of a dose of atropine or hyoscine is advisable to dry up secretions.

Compared with evipan, the inadvisability of using a single dose technique is an obvious disadvantage for single-handed workers. However, on the score of complete safety, the single-handed use of intravenous anæsthetics can never be recommended.

If too large a dose is given and breathing is stopped, artificial respiration should immediately be started and, if necessary, a mixture of oxygen and carbon dioxide given. As with ethyl ether, overdosage always first causes suspension of respiration, the cardiac effect being entirely secondary and due to anoxæmia. As long as satisfactory oxygenation can be maintained, death should never occur from small overdosage. Intravenous injection of coramine appears to be almost a specific antidote in pentothal overdosage, and may be used to shorten the period of unconsciousness following operation. Picrotoxin has been described as a valuable drug in the treatment of barbiturate poisoning (Lovibond and Steel, 1939).

Complications and sequelæ.—The tiresome phenomena that are sometimes seen during evipan anæsthesia, such as muscular tremors and spasm, do not occur with pentothal. As with evipan, repeated sneezing is said to occur, but very rarely. I have used the drug on some 400 occasions and the only complication that I have met has been paroxysmal coughing in two cases, followed by intense laryngeal spasm. In each case a rapid laryngoscopy revealed that this was due to a string of mucus repeatedly falling back on to the glottis. When the mucus had been removed, the coughing stopped and the

spasm relaxed. The recovery period is always quiet and not associated with the restlessness which often follows the use of evipan. I have yet to see a case of post-anæsthetic vomiting or headache after pentothal narcosis. The period of inco-ordination which follows the return of consciousness makes it imperative that the patient should be observed for some hours afterwards. He should never be allowed to drive a car for at least six hours, however normal he may appear to be.

A small proportion of cases develop a minor thrombosis in the vein used for the injection, but the 5 per cent solution lessens this risk considerably. Two or three cases have been reported in which a massive thrombosis has taken place (Payne, 1939).

Contra-indications.—The contra-indications to pentothal anæsthesia are the same as those applied to evipan. Of these the most important is dyspnoea, particularly if caused by partial respiratory obstruction. Others are marked hypotension, sepsis in the mouth or pharynx, and severe liver or kidney disease. I personally regard any operative procedure in the mouth or pharynx, which is likely to interfere with maintenance of a good airway, as a contra-indication, thus limiting the use of pentothal to cases such as the simple extraction of teeth, etc. Incidentally, it should not be given to patients who are being treated with sulphanilamide preparations owing to the sulphur atom contained in the molecule.

Premedication.—If the metabolic rate of the patient is lowered by a preliminary dose of morphia, the scope of pentothal anæsthesia can be considerably extended. The length of anæsthesia can be increased and more traumatic operations undertaken. Although I do not recommend it, on two occasions I have used satisfactorily this anæsthetic alone, when the peritoneum has been opened for perforated gastric ulcer. In my experience, the best form of premedication is a combination of omnopon and hyoscine, and I now use this as a routine. The dosage should be adjusted to the physical and psychic make-up of each individual patient, with particular emphasis on the latter element. In nervous patients these drugs are of the greatest value as they produce a quiet co-operative frame of mind, and, in many cases, actual sleep. Morphine derivatives should always be given at least one hour before operation, so that the full effect on the respiratory centre can be observed before the anæsthesia is begun. The added depressant effect makes it essential that respiration is watched very carefully when giving the pentothal.

The excellent muscular relaxation makes this anæsthetic very suitable for the reduction of fractures, and minor gynæcological operations. Like evipan, it may be used as a method of induction before inhalation anæsthesia for those patients who have a horror of their faces being

(Continued at foot of next column)

NAPHTHALENE POISONING

By N. R. KONAR, M.B.

Senior House Physician, Medical College, Calcutta

H. K. ROY, M.B.

Medical Registrar, Medical College, Calcutta

and

M. N. DE, M.B. (Cal.), M.R.C.P. (Lond.)

Professor of Medicine, Medical College, Calcutta, and
First Physician, Medical College Hospitals

(From the Department of Medicine, Medical College,
Calcutta)

NAPHTHALENE is a hydrocarbon obtained from the middle oil distillate of coal tar. Occurring in large, lustrous crystalline plates, it is easily recognized by its peculiar pungent odour. It is insoluble in cold water, but soluble in hot water, alcohol, ether, chloroform, benzene, and oils. Its industrial use is in the manufacture of indigo and of certain azo dyes. It has also been popularly employed as a disinfectant in the form of moth balls. Occasionally, it has been used internally for therapeutic purposes, as an intestinal disinfectant or vermifuge, and externally, in the form of ointment for pruritus and scabies.

Naphthalene may gain entrance into the body either by inhalation or by ingestion.

(Continued from previous column)

covered. The dose should be kept as small as possible or the decreased respiratory exchange will delay the intake of the inhalation anæsthetic.

No arbitrary statement can be made as to the length of anæsthesia which may be expected with doses of pentothal up to 1 gramme. This depends to a great extent on the operation and on the type of patient. I have seen a large man, who had received 1 gramme during five minutes for the extraction of some teeth, to be awake within the next five minutes. On the other hand, an amputation of the cervix and anterior and posterior colporrhaphy were carried out on a woman, who was given only 0.6 gramme in fifty minutes. Although certain indications may permit of larger doses being used, it is inadvisable to exceed 1 gramme. As a general rule, satisfactory anæsthesia for twenty minutes can be expected in the average patient. It has been pointed out above that the period and depth of anæsthesia can be greatly increased by the use of morphia premedication. For those who have been using evipan, it can be said quite definitely that, other things being equal, pentothal will always provide a better anæsthesia.

Prolonged inhalation of naphthalene vapour is known to have given rise to symptoms of poisoning. Evers (1884) records a case where persons sleeping under bed clothing dusted over with naphthalene as a moth powder developed symptoms of poisoning. Lutz (Mann, 1922) also records three cases of chronic poisoning by naphthalene vapour. Poisoning by ingestion is usually accidental, occurring amongst children or insane persons. Suicidal cases are extremely rare.

The minimum fatal dose of naphthalene taken by mouth is not definitely known. It has been recorded (Mann, 1922) that in a particular case even seven grains of naphthalene produced severe symptoms of poisoning. A boy (Prochownik, 1911), 6 years old, died in two days after taking 1.75 grammes of naphthalene in seven doses as an anthelmintic. Vyas (Modi, 1936) reported a case in which a boy of 2 years died on the third day after he had swallowed a naphthalene ball weighing about 40 grains. A boy (Heine, 1913), 12 years old, who had eaten two naphthalene-camphor tablets ('bon-bons') each containing 2 grammes of pure naphthalene suffered from severe symptoms of poisoning, resembling those of alcohol but he ultimately recovered.

When naphthalene is taken by mouth, it may irritate the stomach and cause nausea and vomiting. This may get the poison out of the body, in which case further development of symptoms does not take place. Mild irritation of the stomach also occurs when the poison has been inhaled. This occurred in the cases cited by Evers and Lutz. If the ingested naphthalene is not vomited, it passes into the small intestine where it becomes absorbed into the portal circulation. Naphthalene is usually taken in an insoluble form, so that in order that it may be absorbed there must occur in the intestine some physicochemical process, which, at present, is little understood. Wieland and Sorge (1916) have shown that naphthalene forms a co-ordination complex with desoxycholeic acid. This complex, naphthalene choleic acid, has been shown to be easily soluble and absorbable. Recent experimental observations of Stekol and Mann (1937), however, do not confirm the rôle played by desoxycholeic acid, as naphthalene may be absorbed even without the presence of bile in the intestine.

The first vital organ which naphthalene meets after its absorption from the intestine is the liver. This organ, vested with the powers of detoxication, attempts to get rid of the poison partly by excreting it in the bile and partly by oxidizing it to β -naphthol and then combining it with glycuronic, sulphuric and mercapturic acids (Stekol, 1935). These products after detoxication pass into the general circulation from where they are filtered out in the kidneys. The liver itself does not remain unhurt during the process; its glutathione content diminishes markedly (Nakashima, 1934) and acute necrosis

of the polygonal cells takes place here and there. This in its turn produces the clinical manifestations of jaundice and cholæmia. A part of the poison which has not been successfully detoxicated enters the general circulation and exerts its harmful effects on various other important structures. Red blood corpuscles may be hæmolyzed, the myocardium may be enfeebled, the higher cerebral centres may suffer functional depression, and the kidneys also may share the general damage. Thus will arise the clinical manifestations of rapidly developing anæmia and even hæmoglobinuria, enfeebled circulation and weakened heart sounds, confusion and coma, albuminuria, cylindruria and hæmaturia. Optic neuritis, cataractous changes in the eye lens and opacities in the cornea may also occur in the chronic forms of poisoning (Bouchard and Charrin, 1886; Leschke, 1934).

We came across some of the above deleterious effects of naphthalene in a fatal case of poisoning, the notes of which we append below. So far as our knowledge goes, this is the second case of fatal poisoning due to naphthalene reported in India, the first report being that of Vyas to which reference has already been made.

Case note

L., Mohammedan, aged 24 years, was admitted into the Medical College Hospital, Calcutta, in a semi-conscious state on 4th June, 1939. The attendant said that the patient took some naphthalene (exact amount was not known) by mistake in place of an Indian sweet on 2nd June.

On examination.—The patient was semi-conscious; axillary temperature 99°F.; pulse rate 120 per minute; respiration rate 28 per minute. He looked pale and severely jaundiced. No signs of trauma were found on the head, neck or body. There was nothing in the breath suggestive of poisoning. Liver and spleen were not palpable. Heart sounds were feeble, lungs clear, pupils equal and reacting well to light. The neck was soft but Kernig's sign was positive. All the tendon reflexes were sluggish. Superficial abdominal reflex was absent. Babinski's sign was positive on both sides.

Twelve hours later, the coma deepened, pallor became more marked, heart sounds became feebler and the rectal temperature rose to 102°F. Systolic blood pressure was 95 and diastolic 48 mm. of Hg. At this stage a lumbar puncture was done. Ten cubic centimetres of clear cerebro-spinal fluid came out under slightly increased pressure.

After another twelve hours, the patient's condition became worse. There was evidence of right-sided hemiplegia. The rectal temperature rose to 103°F. The pulse rate was 142, and respiration 44 per minute. Patient ultimately expired—three days after swallowing the naphthalene.

Laboratory findings.—Blood examination report:—Hæmoglobin 30 per cent; red blood corpuscles—2,410,000 per c.mm.; white blood corpuscles—31,200 per c.mm.; polymorphonuclear cells—90 per cent; lymphocytes—8 per cent; monocytes—2 per cent. No malarial parasites were found. Plenty of normoblasts and marked anisocytosis were noticed.

Urine examination report:—Colour—brown; reaction—acid; specific gravity—1020; turbidity—slight; albumin—trace; sugar—nil; acetone—nil; bile—present. Occult blood test—negative; indican—nil. Microscopically occasional pus cells, few epithelial cells and mucus.

Biochemistry of blood:—Urea—53 mgm. per cent; non-protein nitrogen—46 mgm. per cent; cholesterol—

106 mgm. per cent; chloride—468 mgm. per cent. Van den Bergh reaction—immediate direct positive; bilirubin contents—20 units. Wassermann reaction of blood was negative.

Cerebro-spinal fluid:—Clear fluid, microscopically no pus cells or organisms seen. Culture—no growth.

Autopsy findings.—Rigor mortis all over the body. Pupils dilated. Conjunctiva—markedly icteric. Scalp layer stained yellow. Brain and spinal cord stained yellow. Larynx and trachea—mucus stained yellow and contained froth. Lungs—yellow frothy exudations from sections on pressure. Heart—thin fluid blood on both sides. Peritoneum—stained yellow. Gastro-intestinal tract—mucous membrane yellow. Kidneys—pale. Spleen—congested. Gall-bladder full of bile. Liver—soft, pale.

Histology.—Patchy necrosis of the liver, chiefly in the central zone. Naphthalene was detected in the tissues, in the stomach contents and in the urine by the chemical examiner.

Comments

The remarkable features of the above case were deepening coma, severe jaundice, rapidly developing anæmia, hyperthermia, and patchy hepatic necrosis, as revealed by the post-mortem examination. Such features of naphthalene poisoning have not been frequently noticed by the previous reporters. Indeed, there is no mention of hyperthermia, hemiplegia and marked anæmia in the previously recorded cases reviewed by us. The marked degree of anæmia which developed so rapidly was possibly due to acute hæmolysis, although, in this case, there was no hæmoglobinuria. This hæmolysis enhanced the jaundice primarily caused by hepatic necrosis. Hyperthermia might be explained by the cholæmia consequent to liver necrosis, like the hyperthermia met with in cases of acute yellow atrophy of the liver. It is also possible that, in the metabolism of naphthalene, naphthylamine (an amino derivative) was formed and was responsible for the fever. Naphthylamine has been used by laboratory workers for causing experimental hyperthermia.

Summary

1. A brief review of cases of naphthalene poisoning has been made.
2. Metabolism of naphthalene and its effects on the body have been discussed.
3. A case of fatal poisoning has been described, including its autopsy findings.
4. The possible pathogenesis of the unusual features has been suggested.

We are grateful to Colonel J. C. De, I.M.S., Superintendent, Medical College Hospitals, Calcutta, for the permission to publish the case, to Dr. K. N. Bagchi, Rai Bahadur for the report of the chemical examination of the viscera, to Major D. Ahmed for the post-mortem reports, to Capt. P. De for the biochemical reports and to Prof. B. P. Tribedi for his permission to undertake the histological examinations.

CARDIO-VASCULAR SYPHILIS AND CEREBRAL SYMPTOMS

By P. G. GOLLERKERI, M.D.

Pathology Department, Medical College, Rangoon

THE clinical results of a syphilitic infection have long been described in more or less definite three stages: primary, secondary and tertiary. This division into stages has been possible apparently because of a hypothetical tissue susceptibility of the various types of body tissues at different periods of the infection. We are taught that after the primary sore on the genitals or elsewhere—the lesion at the site of entry of the organism associated with trauma—the skin and mucous membranes follow with a rash, etc., in a regular sequence, and later, after a variable period, the so-called tertiary symptoms appear in the internal viscera.

Anyone with a long clinical experience in a general hospital will have been struck by the number of syphilitics (as proved by the Wassermann reaction) who do not show or give any history of the disease going through the different stages. Often, syphilis in a patient is discovered when he develops signs or symptoms of an aortic aneurysm or of coronary artery damage with thrombosis. Ordinarily, however, a syphilitic does not die of his infection in the earlier stages, or even in the later stages, unless one of the vital organs is involved. A more severe secondary infection, such as tuberculosis, sets in, from the lowered vitality of the syphilitic infection, which kills him off.

The writer still remembers the quaint aphorism that used to be dinned into him during his student days 'Syphilis is the bed on which tubercle is born'. In a general hospital, if a patient comes with symptoms of any disease that cannot be directly referable to a syphilitic infection, these symptoms get diagnosed and treated; and it is only when this treatment becomes unsuccessful, partially or

wholly, that syphilis is thought of. Many cases get involved in a serious major operation, avoidable at any rate in some of them. The clinical history and the subsequent post-mortem examination of a recent case admitted into the Rangoon General Hospital lends colour to the contention that a Wassermann reaction of blood should be a routine procedure with every admission with the slightest doubt about the diagnosis, before treatment is commenced.

J. A., aged 30 years, was admitted on the morning of 20th June, 1939, for the treatment of persistent vomiting which started about 2 a.m. that day. On admission he complained of giddiness and vomited twice within the space of half an hour. Vomiting was effortless and projectile in character and seemed to have no relationship to food. Patient was quite conscious and was calling out for a receptacle whenever he felt the desire to vomit. He also complained of occipital headache. There was no history of a previous attack of this kind, nor of injury or fall to account for these acute and sudden symptoms. The patient denied any history of venereal disease. With a provisional diagnosis of cerebral tumour he was admitted into the wards. Temperature 97.6°F., pulse 84 and respiration 20 at this time.

In the ward, the patient preferred to lie curled up with the head tilted to one side, away from bright light. The eyes showed a right lateral deviation. Though conscious, he took no active interest in his clinical examination or in the surroundings. He was constantly groaning and looked dull and listless. The pupils were equal and reacted sluggishly to light. Abdomen showed some fullness, but was soft on palpation and tender on deep pressure. There was no enlargement of liver or spleen. A feeble peristalsis could be made out on auscultation of the abdomen. The knee and ankle-jerks were present.

Two mornings later, the staff nurse reported that the patient would not talk or take his feeds, so that nasal feeding was resorted to. He showed at this time a left-sided hemiplegia which was not noticed the previous evening—possibly it came on in the course of the night. He had fewer attacks of vomiting now, though he was still apathetic and unconcerned with his surroundings. Temperature—97.2°F., pulse—94, and respiration—32. Routine stool examination was negative for protozoa, ova, cysts and cell exudates. Suspecting a cerebral neoplasm, the skull was x-rayed with the report 'No abnormality to suggest the presence of a new growth'.

In the course of the next few days he seemed to be improving somewhat, having got over his paralytic symptoms and to some extent his gastric symptoms. On the seventh day of admission, it appears he took his feeds in the morning and was able to sit up in bed and use his limbs normally. Towards the evening—about six hours later—he suddenly became worse with intensification of his nausea and a definite left-sided hemiplegia. He died that night after a stay of about a week in the hospital.

Post-mortem examination (about four hours after death)

Body was that of a well-developed male, aged about 30 years. Abdomen somewhat distended, rigor mortis in the upper part of the body. On opening the abdomen distension with gas was noticeable chiefly in the colon and the stomach. A loop of jejunum about 18 inches long showed what looked like a typical hæmorrhagic infarction. The mesenteric vessels of this loop were standing out prominently against the pale fatty background. Cutting into the mesentery across the vessels, long worm-like clots were recovered intact from the lumens. The infarcted (?) loop was abruptly cut off on either side from normal looking intestine. No notable changes were seen in the spleen, liver, kidneys, etc.

In the thorax except for a small solid area (about $\frac{1}{2}$ inch across) in the upper lobe of the left lung, and predominantly a left ventricular hypertrophy nothing grossly abnormal was detected. The valves of the heart looked normal, and the aorta showed a smooth intima. The hypertrophy of the left ventricle was put down to a possible dilatation of the aortic ring without any damage to the cusps themselves. The solitary lung lesion was later proved to be a hæmorrhagic infarct histologically.

The cranium was carefully opened up, as the clinical signs and symptoms pointed to a brain lesion (tumour?). But for a little emptiness of the superficial vessels no gross change was noticeable anywhere. The brain was sliced through various points on the surface after noting the normal appearance and contents of the ventricles. No hæmorrhagic focus, nor any softening could be detected in any of these sections.

After collecting the blood serum from the cardiac chambers for the Wassermann reaction an anatomical diagnosis of syphilis was provisionally made to explain the thrombotic phenomena in the intestine and lung and the ante-mortem clinical symptoms. Fortunately, also the cerebro-spinal fluid drawn the day before his death was also available for the Wassermann reaction. Both the blood serum and cerebro-spinal fluid were put up the same day for the Wassermann reaction and the reports were ++ for blood and ++++ cerebro-spinal fluid.

Comment

Failing to find any other direct pathological evidence to explain the cerebral and the gastro-intestinal symptoms, one has to fall back upon syphilis. Throughout the course of an untreated syphilitic infection, except for the tertiary gumma, the various manifestations can be explained by the minute lesion around the capillaries from an irritation of the blocking by the treponema of the perivascular lymphatics. Histologically, this perivascular inflammation of the smaller vessels is so characteristic that it is often the first hint of the diagnosis of syphilis.

Taking the cerebral symptoms first, the early symptoms were those of irritation and later of hemiplegia. Now, it is well known that when a vessel becomes narrowed, from inflammation and later a fibrosis of its wall, the rate of flow of blood through such a channel becomes slowed down though the blood pressure tends to be greater at its mouth. This slowing down of a column of blood is probably the most important prelude to thrombosis. Thrombotic phenomena in the coronaries and elsewhere, whether from a syphilitic stenosis or from a degenerative sclerosis, have this primary slowing down of the stream for their development. If the vaso-motor nerves add to this organic defect in the vessel by a spasmodic constriction, an acceleration of the development of the symptoms is assured so that the onset would be sudden and acute. Ordinarily, a point in the diagnosis of a syphilitic thrombosis, in a vital organ like the brain, is the comparatively slower development of the signs than those of a hæmorrhagic lesion, though in both these the signs, when fully established, may be the same. On the basis of a slow clotting of blood in some of these cerebral vessels, the symptoms of giddiness and headache, of which this patient complained, can be explained. The

attacks of hemiplegia occurred probably when the vessel segment got more or less completely cut off from thrombosis and vaso-constriction producing severe anæmia of the part supplied by the vessel. For the disappearance of the hemiplegia one has to suppose that the blocked vessel became patent again to allow the required amount of blood to reach the region of its supply. This may easily happen if we suppose that the clot contracted sufficiently and the vaso-dilator mechanism again came into play to let it pass on to the venous side. Contraction of a blood clot is such a familiar phenomenon *in vitro* but there is no reason why this should not take place *in vivo* also. The small infarct found in the lung could possibly be a result of this arterial clot getting into the venous circulation, as reasoned above, and reaching the lung filter through the branches of the pulmonary artery.

The gastro-intestinal symptom of vomiting, described as effortless and projectile, is quite easy of explanation. The post-mortem finding of a loop of jejunum definitely cut off from the rest of the bowel in an infarction suggests that these were symptoms of a paralytic ileus. Acute intestinal obstruction brought about by paralysis of a loop or any part of the bowel (like the appendix) is well known to produce these violent symptoms, which, with their spasmodic nature and absence of a definite local history prior to onset, are apt to be mistaken for a symptom of central origin as happened in this case. A 'cerebral tumour' was the provisional diagnosis and attempts to substantiate this by x-rays, etc., led to the undoing of the clinicians in the correct diagnosis of the case.

But for the Wassermann reactions of the post-mortem blood and ante-mortem cerebro-spinal fluid (which was drawn only as a therapeutic measure to relieve pressure) the ante- and post-mortem evidence of syphilis is very obscure. The aorta in tertiary syphilis in a young man shows the characteristic longitudinal fissuring of the intima, so aptly likened to the crinkling of a tree bark. In the present case the intima of the aorta was quite smooth and the myocardial hypertrophy of the left side was put down to a dilatation of the aortic ring rather than to any defect in the cusps of its valve. In none of the other internal organs was there any syphilitic stigma detectable with the naked eye.

Summary

A fatal case of cardio-vascular syphilis is described in which the signs and symptoms ante-mortem pointed to a tumour of the brain. Explanation of these symptoms is attempted from the pathological evidence obtained at the post-mortem examination. A case for a routine blood test for syphilis, of all cases coming to a hospital without a straightforward diagnosis, is made out.

CALCIFICATION OF RENAL TUMOURS

By HERSCHEL C. ALDRICH, B.A., M.D. (Ohio State University, U. S. A.)

Nadiad

THERE are very few references in the literature to calcified renal tumours. A few of the standard textbooks on urology mention that calcification of renal tumours occurs under certain conditions. Braasch and Griffin (1936) of the Mayo Clinic report on the significance of the radiographic evidence of calcified deposits in renal tumours in relation to prognosis. Cahill and Melicow (1938) of the Presbyterian Hospital, New York, report a series of 118 renal tumours since 1929. Eighty-two of these tumours were of the renal parenchyma, as proved by operation and pathology; 16 were of the renal pelvis, and the remaining 30 were Wilms tumours, fibromas, fibro-sarcomas and leiomyosarcomas, together with a few cases which because of markedly diffused metastasis were neither operated on nor classified. Of this series of 118 renal tumours, careful study of the roentgenograms showed 14 cases in which calcification could be demonstrated. Twelve of these 14 cases were subjected to nephrectomy, and, in all of these cases, the tumour was of the renal parenchyma. Several cases of tumour of the renal pelvis had intrapelvic calculi, but in none of these cases was there any evidence of calcified shadows within the tumours themselves. Pathological sections of the 12 tumours operated upon showed in all a hyper-nephroid carcinoma. Braasch and Griffin in their series found that the prognosis in calcified renal tumours was better than in those not calcified; while Cahill and Melicow found the reverse to be true.

The calcification seen in parenchymal renal tumours must be differentiated from renal lithiasis and from somewhat similar calcification occasionally observed in renal tuberculosis. More rarely calcified retro-peritoneal and mesenteric lymph nodes, and perhaps calcified guinea-worm deposits, when situated in such a position as to overshadow the kidneys, may have to be considered. The calcification in renal tuberculosis is usually of a more general and evenly-deposited mottled type. Renal tuberculosis and renal lithiasis can usually be

(Continued from previous column)

I am indebted to Mr. B. Veda of the final M. B. class of this college for parts of the clinical history of the case, and to Dr. U Ba Than, M.B., F.R.C.S.E., police surgeon, Rangoon General Hospital, for his kind permission to investigate the case post mortem.

Since writing the above paper, the writer came across an editorial on the subject of spasm of the cerebral arteries in the *British Medical Journal* (1939, i, p. 1292), with obvious significance *a propos* the views expressed in this paper.

excluded by a careful cystoscopic examination, including retrograde pyelograms and a careful study of the clinical data. The calcification seen in parenchymal renal tumours may occur in various forms. Typically, however, the shadows occur in irregular clusters and strands. Deposits of this typical appearance occur only in parenchymal renal tumours.

The pathology of calcification in any tumour is one of areas of hæmorrhage within the tumour substance, followed by necrosis and then calcification.

In a series of 2,102 roentgenograms taken at the American Methodist Mission Hospital from 1st November, 1933 to 1st August, 1939, there have been 579 covering the area occupied by kidneys and renal tumours. In this general group of 579 abdominal roentgenograms, there were six diagnosed as renal tumours or possible renal tumours. This series of renal tumours does not include some eight or ten cases of very large cystic renal tumours found in young children of which roentgenograms were not taken because of the obvious diagnosis. Two of the six cases showed calcified deposits; one was diagnosed as an advanced tuberculous kidney, and proved to be such; the other was diagnosed as a malignant parenchymal tumour with areas of calcification. The report of this case follows:—

Case note

Male, aged 45, Hindu Patel by caste. This patient when first seen presented himself with a purulent urethral discharge of some four days' duration and complained of burning and frequency of urination. He denied previous discharges. Urethral smear was

Case no. 6647.
Calcified renal tumour.

taken, and the laboratory reported numerous Gram-negative intracellular diplococci. The case was diagnosed as that of a recurrent chronic gonococcal prostatitis. This patient was next seen three weeks later, at which time the discharge was still unchecked, and the prostate on examination was found to be irregularly enlarged and very hard in consistency, suggestive of malignancy. The treatment for the urethral discharge was continued. A week later the patient returned and at this time the discharge was much less. The chief complaint of the patient at this visit was much difficulty

YAWS IN CHATRA SUBDIVISION OF HAZARIBAGH DISTRICT, CHOTANAGPUR

By G. N. SINHA, L.M.F., L.T.M.

Medical Officer, Pratappur District Board Dispensary

THE disease is prevalent in Pratappur *thana* of this district. This *thana* is in a very out-of-the-way part of the district on the border of Palamaun and Gaya districts. It is reported that this disease has been known to exist in this area for a long time and it is known as 'Saoiya ghao'. Although this dispensary was opened in 1921, it appears from the previous

(Continued from previous column)

was taken following a barium enema. This showed a partial obstruction of the descending colon due to a large pear-shaped calcified tumour, apparently originating from the left kidney and displacing the colon laterally. A cystoscopic examination was made a week later. The findings at this examination were as follows:—

A no. 24F cystoscope was passed into the bladder with moderate obstruction in prostatic urethra. The bladder mucosa showed no signs of inflammation. However, there were noticed several strands of thick muco-purulent material resting on the bladder mucosa near the ureteric orifices. The ureteric orifices were normal in appearance.

A no. 5 ureteric x-ray catheter was introduced up the left ureter to a distance of 17 cm., where an impassable obstruction was met.

A no. 5 ureteric x-ray catheter was passed up the right ureter to a distance of about 2 cm. where it was obstructed and could not be introduced further. Specimens of urine were obtained from the bladder and both right and left kidneys. The laboratory report on these specimens showed the presence of pus in all the three. No organisms were found. (Cultures were not made.) A retrograde pyelogram was made after the injection of sodium iodide solution on the left side. A photograph of the roentgenogram obtained accompanies this report. The points to be noticed in this are: A large pear-shaped tumour apparently attached to, or a part of, the left kidney showing extensive areas of calcification mottled irregularly and in strands. The renal pelvis is deformed and flattened in appearance showing a type of defect frequently found in renal tumours. The ureter is bifurcated (congenital defect). A diagnosis of left renal parenchymal tumour (carcinoma) was made in this case and an operation advised. The patient however refused.

Summary

1. Calcification of renal tumours occurs occasionally and is found typically in malignant parenchymal tumours.

2. The roentgenographic findings in such cases, as a rule, are such as to make the diagnosis certain.

3. A report is given of one case of such a tumour found in a series of 579 routine and special roentgenograms taken covering the abdomen.

records that no case was diagnosed here till December 1938, by the writer. No other cases have been seen by the writer in other parts of the district but it is endemic in this *thana*. From a record of 52 cases it appears that the disease occurs most frequently among Bhuiyas, Dusads, Ganjhus, Ahirs and Turis but is also found among other castes. Higher Hindu castes such as Kayasthas, Brahmins and Rajputs generally escape, probably because of their greater cleanliness. It is less common amongst Mohammedans. It is more common amongst the males. Children and adolescents are mostly affected although no age is exempt. The study of the source of infection showed that about three-fourths were from near relatives and others from distant relatives or non-relatives. Several cases in one family are frequently found. Regarding the transmission of the disease, it was found that in 90 per cent of cases there was a definite history of contact.

A characteristic feature of the disease in this locality is the persistence of the primary lesion together with the secondary lesions for several months. The primary sore was extra-genital in every case. Constitutional symptoms such as pains in joints, muscles and bones are generally absent in the primary stage in about 50 per cent of the cases, but they become very severe in about 40 per cent of the cases in the secondary stages, so much so that the sufferers often pass restless nights and become quite unable to do their ordinary work. The secondary eruptions were found mostly on the face, angles of the mouth, axillæ, genitals, perineum and extremities and there were a few on the trunk. The secondary lesions together with the pains of rheumatic type last from several months to one to two years. Pains in joints persist even after the healing of the eruptions in about 80 per cent of cases. Lesions on the palms and soles were found only in 10 per cent of cases. Circumscribed painful periosteal nodes were seen on the anterior aspects of both tibiæ in one case only. Gummatous nodules and chronic indolent ulcers on the extremities were generally seen in the tertiary stages. In some cases deformities of the extremities were found. Recurrences of secondary lesions were reported in about 50 per cent of the cases. Death from the disease is practically unknown.

Treatment.—Novarsenobillon (N. A. B.) and Mapharside (Parke, Davis and Co.) were given and the results were so remarkable that now patients from distant villages come here for treatment whereas previously they had an idea that there was no cure for their disease. N. A. B. from 0.3 to 0.45 gm. or mapharside 0.04 to 0.06 gm. was injected intravenously, the dose being repeated at 5 to 7 days' intervals. The number of injections necessary varied from 3 to 4. The immediate result of this mode of treatment was very satisfactory in all primary

WILLETT'S FORCEPS

A COMMENTARY ON THEIR VALUE IN THE TREATMENT OF PLACENTA PRÆVIA, ESPECIALLY AS APPLIED TO INDIAN CONDITIONS

By J. EDIS-MYERS, M.R.C.O.G. (Lond.)

CAPTAIN, I.M.S.

District Medical Officer, Bellary

WILLETT (1925) first published his account of the treatment of placenta prævia by scalp forceps and weight traction, in 1925. He describes the treatment of seven cases by means of a modification of de Martell's surgical scalp forceps—the modification being the increase in length of the handles to $7\frac{1}{2}$ inches. His two resident medical officers assured him that they found the method both easy and quick, and that it never failed to check the bleeding.

Jennings (1932) has used Willett's forceps in over fifty cases and personally prefers them to other methods of treatment, although he does not quote any figures. Vignes and Tisserand (1937) both consider the method excellent. Their opinion is that the indications for Cæsarean section are diminished. They quote Gauss (1934) as having excellent results.

von Pall (1936), out of fifty cases, has used the method seventeen times in $5\frac{1}{2}$ years. In the

(Continued from previous column)

and secondary cases, except in one mild case where there was relapse following apparent cure after one injection of N. A. B. 0.45 gm. Mapharside was found superior to other arsenicals and no toxic symptoms were seen in any case after its use. Weak and debilitated patients tolerate it well. Arseno-paritran (Bathgate and Co.) was used intramuscularly in one case but the result was not encouraging.

Bismuth salts.—Bismuth oxychloride, bismuth cream (B. W. and Co.) and bismo-paritran (Bathgate and Co.) were tried in doses of 1 to 2 c.cm. intramuscularly bi-weekly on account of the high cost of N. A. B. and allied preparations. The number of injections varied from six to eight but the results were slow and not so satisfactory and the patients began to discontinue attending for injections as the result was not so prompt. Locally boric ointments were given to apply. During convalescence, an iron tonic mixture was given. Potassium iodide orally was found ineffective.

My thanks are due to Messrs. Parke, Davis and Company and Bathgate and Company for their kindly supplying me free samples of mapharside and paritran (arseno and bismuth) for trial.

I am indebted to Rai Sahib Dr. S. B. Dutt, Civil Surgeon, Hazaribagh, for his kindly going through the article and for his permission to publish this note.

other cases, there were two cases not requiring treatment, seven cases had membranes ruptured artificially, five cases of Braxton-Hicks version, three cases treated by de Ribe's bag, and six cases of Cæsarean section. He does not quote any figures.

These findings coincide with ours in Madras. We have been using the same type of forceps as described above and have found them most satisfactory. For a time we were using a pair with handles 11 inches long, but we found that the grip on the scalp was definitely weakened by the added length of handle and we went back to the 7½-inch handle.

Since 1925, Willett's forceps have proved their worth as a method of treatment.

Advantages

1. In many cases they can be applied without an anæsthetic (cases 2, 3, 5, 6 and 7).

2. Their application entails a minimum amount of manipulation—a valuable advantage in cases which are first seen in a state of collapse after a severe hæmorrhage (case 1).

3. They can be applied effectively with the os only one-fifth dilated (cases 7 and 4). The only alternative treatment here would be Cæsarean section with all the multitudinous necessities which that entails.

4. Their application does not need any special knowledge or skill. The accoucheur should be quite competent after one or two applications.

5. It enables the accoucheur to make use of the normal and best dilator of the cervix—namely, the head.

6. As regards the fœtus, all the dangers and fatalities of manipulation are eliminated. The only complications liable to ensue from the use of the forceps are those due to injury to the scalp, which is uncommon and generally of a localized and minor nature.

7. The instrument itself takes up very little room, does not deteriorate with age, and it is of a type with which all medical men are familiar, namely the scissor handles and ratchet. It is sterilized very simply and completely, namely, by boiling.

8. They employ the natural dilator, namely, the head and consequently this undergoes normal moulding. There is therefore little risk of cranial damage to the fœtus—compare the after-coming head in a breech after version (Browne, 1937).

Disadvantages

1. In cases of central placenta prævia, the application is made more difficult by the necessity of having to tear through the placenta first. If, however, treatment other than Cæsarean section is employed, namely, de Ribe's bag or

podalic version, this manœuvre still has to be carried out, consequently this disadvantage is nullified.

Central placenta prævia is rare as compared with lateral cases and is generally of such a grave import that Cæsarean section is the only satisfactory treatment.

Here again, I venture to suggest that, if Cæsarean section cannot be carried out owing to the local circumstances, Willett's forceps can be used with greater advantage and more easily than de Ribe's bag and podalic version.

2. The forceps are liable to come off if the labour is at all protracted or the patient very restless (case 2). This disadvantage is of a minor nature, however, in that they are easily reapplied and the restlessness can be treated with appropriate drugs.

Case 1 is an instance of the value of Willett's forceps. She was an 11th-para admitted in an exhausted semi-conscious state with all the signs and symptoms resulting from a severe loss of blood. She was definitely in no fit state to undergo any extensive operative or manipulative treatment. I am quite certain in my own mind that any interference of this nature would have killed her very quickly.

Willett's forceps were put on with no difficulty and they absolutely stopped all further bleeding. The patient was delivered six hours after their application.

The os was only two-fifths dilated and version would have been difficult, if not impossible, and would have entailed further bleeding which, added to the extensive hæmorrhage that she had had, almost certainly would have brought about a fatal issue.

The shock and hæmorrhage attendant on a Cæsarean section would have caused the same result.

As it was, the mother nearly expired two or three times after delivery and sustained uterine sepsis during the puerperium from which she slowly recovered.

Taking all the evidence and weighing it with an unbiassed mind, I feel certain that Willett's forceps undoubtedly saved this mother's life, and that no other means of treatment could have done so.

It would appear, therefore, that for cases which are *in extremis*, we have in these forceps a very useful and powerful means of turning what is to all intents and purposes a hopeless case into one with a successful termination. It is at once apparent that Willett's forceps should prove to be a boon to the country practitioner in most countries and more so than ever in India.

In India most of the village communities live some distance from a big hospital with a staff

capable of performing Cæsarean section, but there are numerous small dispensaries in charge of a doctor and most villages are near a medical man.

A doctor trained in the use of Willett's forceps therefore has all that he requires to treat a case of placenta prævia reasonably successfully. He can carry out all the treatment that is necessary.

For most of the country people in India, getting to a fully-equipped hospital is out of the question—distances are too great and more often than not the only means of transport is the bullock cart. Cæsarean section is not therefore a possible means of treatment.

The local doctor can then consider the possibility of doing a podalic version. Supposing him to be familiar with this manœuvre, it still has many dangers and contra-indications. Sepsis is more or less certain to follow intra-uterine manipulations in the Indian climate in the *mofussil*, which without hospital facilities is fairly certain to prove fatal.

He can consider using de Ribe's bag. This is practically an impossibility, as in India they perish very rapidly and the ordinary practitioner is therefore not trained in their use.

There remains vaginal packing which is at the best a poor hæmostatic and unless properly performed under an anæsthetic is no use at all. Here again the possibility of sepsis supervening is great.

We now come to the latest means—Willett's forceps.

1. The Indian practitioner, with very little training with this instrument, can become quite a competent performer.

2. They are reasonably cheap to buy. The average practitioner in India is far from being a wealthy man.

3. They are indestructible in the Indian climate.

4. They are easily carried and very easily sterilized by the simplest means of all—boiling—available in the smallest and most primitive Indian household.

5. They involve no more manipulation or handling of the parts than is done in a vaginal examination.

6. They give very good hæmostasis without the necessity of an anæsthetic—the latter sometimes an impossibility in the Indian countryside.

7. Labour generally progresses evenly and successfully, with termination in a moderate time after application. This is reassuring and comforting to the patient, the doctor, and also the relatives.

The results as regards foetal and maternal mortality in the Hospital for Women and

Children, Madras (Hospital Reports, 1932–1936), for the last five years are as follows:—

		MOTHER		CHILD	
		Number of cases	Died	Still-born	Died
1936	Willett's forceps	5	1	3	2
	Cæsarean section	1	1	..	1
	Int. podalic version	2	0	..	1
	Bi-polar version	1	0	1	..
1935	Willett's forceps	11	0	4	1
	Cæsarean section	8	4	1	3
	Int. podalic version	6	1	2	2
	Bi-polar version
1934	Willett's forceps	3	1	1	1
	Cæsarean section	1	0	0	1

The cases in these tables are those in which only the following obtained:—

1. Vertex presentation only.
2. Cases which needed interference in order to stop the bleeding.
3. Cases which were not complicated in any other way.

Other cases, *e.g.*, placenta prævia with a breech presentation or placenta prævia not necessitating any active interference, etc., are not included as they are not germane to the subject.

It will be seen from the above tables that there were 57 cases of placenta prævia with otherwise uncomplicated vertex presentation necessitating active interference to stop hæmorrhage.

Of these 57 cases:—

Twenty-six (45.6 per cent) were treated by Willett's forceps with a maternal mortality of 2 cases = 7.7 per cent, and a foetal mortality of 16 = 61.5 per cent.

Ten (17.5 per cent) were treated by Cæsarean section, with a maternal mortality of 5 = 50 per cent, and a foetal mortality of 6 = 60 per cent.

Twenty-one (36.8 per cent) cases were treated by podalic version with a maternal mortality of 5 = 23.8 per cent, and a foetal mortality of 15 = 71.4 per cent.

These mortality figures, taken all round, are very high—much higher than the English figures, but the type of patient treated in Madras has to be taken into account—generally overworked, under-nourished, anæmic and

diseased. In addition these are the record of cases which all needed interference on the part of the obstetrician in order to stop bleeding.

Statistics are notoriously far from being infallible, especially in such a very small number of cases, but there is, I think, sufficient evidence here to prove that in Willett's forceps we have a very valuable means of treating placenta prævia—a means which is within the power of any medical practitioner to apply in whatever circumstances and environment he may practice.

I wish to thank Major-General N. M. Wilson, Surgeon-General with the Government of Madras, for permission to publish this commentary.

Case 1, age 35 years, Hindu, 11 para. Admitted 24th August, 1937, at 1-30 a.m.

Previous pregnancies and confinements all normal. Has been in labour since 11 a.m., 23rd August, 1937. Complaints of painless bleeding on and off since onset of pains. Examined outside by corporation nurse.

Examination.—Exhausted, semi-conscious, restless, sighing respiration. Anæmic. Heart and lungs—nil abnormal. Pulse—124. Fair volume. Regular. Temperature—98. Urine—bladder empty. Fœtal heart—143. Regular. Heard to the left and below umbilicus. Blood pressure—110/70.

Palpation.—(1) Height of uterus—38 weeks. (2) Condition of uterus—not contracting. (3) Position of fœtus—vertex. L. O. A. Head floating above brim. Can be made to engage.

Vaginal examination.—Os 2/5 dilated. Placental tissue felt posteriorly and laterally. Membranes entire. Head presenting. Rather profuse bleeding. Blood pressure—105/80.

2 a.m.—Under light chloroform anæsthesia. Membranes ruptured artificially and Willett's forceps applied. 1½ lb. weight attached. Patient very restless. Morphia gr. 1/8 injected subcutaneously. M. P. 126. Volume and tension poor.

4 a.m.—Fœtal heart not audible. No bleeding.

4-50 a.m.—No pains. M. P. 100. No bleeding.

6-35 a.m.—Strong pains. Head fixed and going through. No bleeding.

8 a.m.—Birth of male child—deeply asphyxiated, 8 lb. in weight. Revived with difficulty.

8-35 a.m.—Placenta expressed, entire. After nearly expiring several times during the next 24 hours, the patient improved, but developed uterine sepsis which cleared up with treatment, and she was eventually discharged fit.

The baby after being revived twice, finally expired a few hours after birth.

Case 2, age 16 years, Hindu, 1st para. Admitted 28th November, 1937, at 12-10 p.m.

Complains of bleeding since 4 a.m. to-day. Has been in labour since 3 a.m. yesterday. Examined outside by corporation nurse.

Examination.—Not anæmic. No cedema. Heart and lungs—nil abnormal. Pulse—118. Good volume. Regular. Temperature—98. Urine—1020 acid. Nil abnormal. Fœtal heart—138. Heard on right side below umbilicus. Blood pressure—110/80.

Palpation.—(1) Height of uterus—full time. (2) Condition of uterus—contracting feebly. (3) Position of fœtus—vertex. R. O. A. Head appears to be fixing. Can be pushed well into the brim. No disproportion.

Pelvic measurements.—Int. C.—9½ inches. Int. S.—8½ inches. Ext. C.—7½ inches.

Vaginal examination.—Os 2/5 dilated. Membranes present—thin over the head which is presenting. Placental tissue felt anteriorly and to the left.

12-20 p.m.—Membranes ruptured. Bleeding recommenced. Willett's forceps applied without anæsthetic and 1½ lb. weight attached. No bleeding.

2-45 p.m.—The patient pulled the forceps off. Re-applied. No bleeding.

4-20 p.m.—Birth of live male child, 4½ lb. weight. There was no bleeding after 12-20 p.m. M. P. 76.

4-30 p.m.—Placenta expressed. Entire. The patient made an uninterrupted recovery.

The baby was premature and very weakly but was alive and taking food on discharge from hospital.

Case 3, age 30 years, Hindu, 6 para. Admitted 24th May, 1937, at 3-20 p.m.

Previous pregnancies and confinement all normal. All children alive.

Now complains of painless bleeding at 3 p.m. yesterday and again this morning at 11 a.m. Has had slight labour pains since early this morning.

Examination.—Anæmic. Heart—boundaries normal. Systolic murmur not conducted outwards. Lungs—nil abnormal. Pulse—92. Temperature—98.4. Urine—1010 acid. Nil abnormal. Fœtal heart—140. Heard on left side below umbilicus. Blood pressure—115/70.

Palpation.—(1) Height of uterus—full time. (2) Condition of uterus—contracting. (3) Position of fœtus—vertex. L. O. A. Head up and floating. Cannot be pressed into brim. There seems to be no disproportion.

4-15 p.m.—*Vaginal examination*. Os 2/5 dilated. Membranes thin over the head. Head high up. Placental tissue felt on right side. Bleeding profusely after examination.

4-30 p.m.—Willett's forceps applied without anæsthesia. 2 lb. weight attached. Bleeding stopped.

5-30 p.m.—Patient has lost about 5 ounces of blood since forceps were applied. Pulse—120. 1/4 c.c.m. pituitrin given.

9-50 p.m.—Birth of live female child 5½ lb. in weight. M. P. 100. Has had no bleeding since 5-30 p.m.

10-7 p.m.—Placenta expressed. Fair amount of bleeding with it. M. P. 136. Placenta entire. Rupture in membranes next to placental margin.

After rather a shaky 24 hours, the puerperium was normal and the patient made an uneventful recovery.

Case 4, age 22 years, Hindu, 2 para. Admitted 25th March, 1937, at 6-10 a.m.

Previous pregnancy and confinement—normal. Child died soon after birth.

Now complains of bleeding since 5 a.m. to-day. Has no labour pains. Not examined outside.

Examination.—Not anæmic. No cedema. Heart and lungs—nil abnormal. Pulse—64. Temperature—98.4. Urine—1020 acid. Nil abnormal. Fœtal heart—not heard. No fœtal movements. Blood pressure—130/100.

Palpation.—(1) Height of uterus—30 weeks. (2) Condition of uterus—not contracting. Soft. (3) Position of fœtus—vertex. L. O. A. Head floating. Can be engaged in brim.

Vaginal examination.—Cervix soft. Os one-finger, loose. Head presenting. Blood clots in vagina. Placental tissue felt posteriorly. Membranes absent. Patient to be watched for further signs of bleeding.

9 a.m.—Bleeding recommenced. Under CHCl₃ anæsthesia, Willett's forceps applied, 1½ lb. weight attached.

5-30 p.m.—Birth of still-born female child, weighing 4 lb. The patient had no bleeding since the application of the Willett's forceps.

6 p.m.—Placenta expressed. Membranes were ruptured near placental margin.

The patient made an uneventful apyrexial recovery.

Case 5, age 30 years, Hindu, 4 para. Admitted 13th May, 1937, at 12-50 p.m.

Previous pregnancies.—All three normal pregnancies and confinements.

Complains of slight pains for the last three days and bleeding since 9 a.m. to-day. Examined outside by barber midwife.

Examination.—Not anæmic. Heart and lungs—nil abnormal. Pulse—104. Temperature 99. Urine—bladder empty. Fœtal heart—136. Regular. Heard on right side below umbilicus. Blood pressure—120/80.

Palpation.—(1) Height of uterus—full time. (2) Condition of uterus—rather tense. Not very tender.

Contracting strongly. (3) Position of foetus—vertex. Head not fixed. ? R. O. A.

Vaginal examination.—Os 2/5 dilated. Membranes present. Vertex presenting. Placental tissue felt to the left and posteriorly. Bleeding moderately fast.

1-30 p.m.—Willet's forceps applied without anaesthetic. 2 lb. weight attached (1½ lb. did not seem to quite stop the haemorrhage). Urine—1010 acid. No albumin.

5 p.m.—Not having very strong pains. Very slight amount of bleeding. Foetal heart 116. Irregular.

11-20 p.m.—After increasingly strong pains from 6 p.m., birth of a deeply asphyxiated male child. Could not be revived. M. P. 100.

11-55 p.m.—Placenta expressed. Entire. M. P. 102. The patient made an uninterrupted recovery. No puerperal rise of temperature or bleeding.

Case 6, age 35 years, Christian, 8 para. Admitted 4th May, 1937, at 9 a.m.

Previous pregnancies and confinements.—First six all natural and children alive. Seventh pregnancy—abortion.

Complaints of painless bleeding since last night. This is the first bleeding. Has been in labour since 1 a.m. to-day. Slight bleeding present now.

Examination.—Slightly anæmic. Heart and lungs—nil abnormal. Pulse—124. Temperature—98.4. Urine—Bladder empty. Foetal heart—130. Regular. Heard on right side below umbilicus. Blood pressure—130/75.

Palpation.—(1) Height of uterus—37 weeks. (2) Condition of uterus—contracting feebly. (3) Position of foetus—vertex. R. O. A. Head floating, but can be pressed into pelvic brim.

Vaginal examination.—Os 2/5 dilated. Membranes present. Vertex presenting. Placental tissue felt to the left and posteriorly. Patient bleeding freely.

9-30 a.m.—Membranes artificially ruptured. Willett's forceps applied without anaesthesia. 1½ lb. weight attached. No bleeding at completion.

12 noon.—Patient having strong pains. No bleeding.

12-45 p.m.—Birth of live male child. Weight 7 lb. M. P. 120.

1 p.m.—Placenta expressed

1-20 p.m.—No bleeding.

Patient had a mild urinary infection during the puerperium which cleared up with cytotropine. The lochia were healthy throughout.

First and second stages—12 hours.

Third stage—15 minutes.

Case 7, age 25 years, Hindu, 2 para. Admitted 27th September, 1937, at 8-15 a.m.

She gives a history of previous pregnancy and confinement normal. Has had slight pains for one hour only. Reports slight bleeding per vaginam from 6 a.m. Has had no previous bleeding.

Examination.—General condition good. Heart and lungs—nil abnormal. Has slight oedema of legs ? filarial. Has not been examined outside. Pulse—96. Temperature—97. Urine—1010 acid. No albumin or sugar. Foetal heart—144. Heard on the right side below umbilicus. Regular. Blood pressure—148/100.

Palpation.—(1) Height of uterus—36 weeks. (2) Condition of uterus—contracting. (3) Position of foetus—vertex. R. O. A. Head floating. Cannot be pressed into brim, though there seems to be no disproportion.

Pelvic measurements.—Int. C.—8½ inches. Int. S.—7½ inches. Ext. C.—6½ inches.

There was no bleeding and few pains on arrival in hospital.

4-35 p.m.—Bleeding again commenced and a vaginal examination was done. P. V. Os 1/5 dilated. Vagina full of blood clot. Membranes absent. Vertex presenting—high up. Placental tissue felt to the left and posterior. Temperature—98.4. Pulse—80. Foetal heart 152. Willett's forceps applied without anaesthesia and 1½ lb. weight attached.

5-15 p.m.—Patient having strong pains. Foetal heart not heard. M. P. 85. Patient has not bled since forceps were applied.

AN OUTBREAK OF EPIDEMIC DROPSY IN A CLOSED COMMUNITY

By C. L. PASRICHA

MAJOR, I.M.S.

Professor of Bacteriology and Pathology

S. LAL

Research Worker, Indian Research Fund Association

K. S. MALIK

Biochemist, Indian Research Fund Association

and

P. K. BISWAS

Resident Surgeon, Eye Infirmary

(from the Epidemic Dropsy Enquiry, Indian Research Fund Association, School of Tropical Medicine, Calcutta)

AN outbreak of epidemic dropsy amongst boys living in an institution was recently studied. As there were certain interesting features in this outbreak a short account of it is recorded.

The boys are housed well and lead a healthy well-regulated life. They receive a varied and a well-balanced diet. Each boy is given half a pint of milk and two big slices of bread with molasses in the morning. The midday meal consists of rice, pulses and fresh vegetables as curries cooked in mustard oil and fresh fruits. The evening meal is similar to the midday meal with the addition of animal protein which consists of fish on five days and fresh meat on the other two days of the week. This community had been free from epidemic dropsy since 1933 in which year nearly half the number of the boys had been affected. From January 1939, 242 boys ranging from 12 to 18 years of age were kept under medical observation.

In January 1939 two of the boys developed sarcoids. There was a history of mild diarrhoea lasting two days. In one boy there was slight oedema of the legs, in the other boy although there was a history of heaviness and swelling of the legs there was no oedema at the time of the examination. There were no other signs or

(Continued from previous column)

6-30 p.m.—Birth of still-born male child. 6 lb. in weight.

6-55 p.m.—Placenta expressed. Entire. Membranes ragged.

First and second stages—11½ hours.

Third stage—25 minutes.

Patient made uneventful recovery and was discharged on 9th October.

symptoms. No other cases occurred till May 1939 when 11 boys reported sick and were found to have œdema of the legs. In June 1939 further cases occurred and as a result of the examination of the 242 boys living in this colony 37 boys were found to have signs and symptoms of epidemic dropsy.

The initial symptoms in the majority of the affected boys were mild diarrhœa and fever lasting two to three days, followed by œdema of the legs. The outstanding features in this outbreak were:—

(1) The development of sarcoids in 17 or 46 per cent of the 37 boys affected. The distribution of sarcoids was as follows—head and neck 2, front of trunk 11, back of trunk 4, arms 1, legs 10. The size of the sarcoids was variable, from a pin-point to 8 mm. with the majority about 2 to 4 mm. in diameter. Sections of sarcoids removed from two of the patients gave microscopic appearances similar to those recorded by Chopra, Choudhuri and Panja (1935).

Intradermal injections of ground-up freshly-removed sarcoids into man and laboratory animals gave negative results. Intradermal inoculations in the supra-orbital tissues of a monkey also gave negative results. The latter were done to exclude infection by an organism resembling *Bartonella bacilliformis*, the causative organism of verruca in which the nodules have a superficial resemblance to the sarcoids of epidemic dropsy.

(2) The eyes of the 37 affected boys were examined with results summarized in table I.

(ii) One boy had definite cupping of the fundus with intra-ocular tension within normal limits. He complained of 'haloes'. This boy was probably recovering from glaucoma.

(iii) In one boy the cornea was slightly œdematous but the ocular tension was within normal limits (30 mm. and 35 mm.). The disc was normal in appearance.

As a control, 16 boys living in the same colony and who had no symptoms of epidemic dropsy were examined for the presence of increased tension or changes in the disc. Nothing abnormal was noted in any of these boys.

The affected boys were examined a month later. The intra-ocular tension had become normal and there were no subjective symptoms.

(3) Eight or 22 per cent of the 37 boys suffering from epidemic dropsy had traces of albumin in their urine and in four boys granular casts were present in centrifugalized deposit. Calcium oxalate crystals were seen in 15 of the 37 samples of urine examined.

(4) The sedimentation rate of red blood cells of 16 of the affected boys was estimated, employing Westergren's method. The cell volume, the hæmoglobin and the fibrin nitrogen content were also determined (table II).

The sedimentation rate is increased in epidemic dropsy. The average sedimentation rate (corrected) of a control series of 24 healthy individuals was found to be 6.86 mm. in 1 hour. The fibrin nitrogen content is also increased but is within the high normal limit, the

TABLE I

The results of the examination of the eyes of the 37 boys suffering from epidemic dropsy

Serial number	Cornea media	Fundus oculi	INTRA-OCULAR TENSION (MM.)*		Subjective symptoms
			Right eye	Left eye	
1	Clear	Healthy	55	55	Haloes, pain, dimness of vision.
2	"	"	45	50	Haloes, burning and watering.
3	œdematous	"	45	45	Haloes, burning and watering.
4	Clear	"	43	35	Burning and watering of eyes.
5	œdematous	"	30	35	Dimness of vision.
6	Clear	'Cupping'	25	31	Haloes.
7-37	"	Healthy	20-30	20-33	No eye complaint.

* The tension was estimated with a MacLean's tonometer.

From the results summarized in table I it will be seen:—

(i) Four of the 37 boys had increased ocular tension. These boys complained of burning sensation (three boys), 'haloes' (two boys) and dimness of vision (one boy—tension 55 mm. in both eyes). In one boy the cornea was œdematous with a healthy disc suggesting early glaucoma.

average normal fibrin nitrogen content being 30 mgm. per 100 c.cm. of blood.

A study of table II suggests that the sedimentation rate, the fibrin content and the cell volume are interrelated. An increase of fibrin leads to increase of sedimentation rate provided the cell volume is the same. An increase of cell volume decreases the sedimentation rate provided the fibrin content is constant.

TABLE II

The sedimentation rate, fibrin nitrogen content, cell volume and hæmoglobin in 16 boys suffering from epidemic dropsy

Sedimentation (mm.) after 1 hour	Fibrin nitrogen (mgm. per 100 c.cm.)	Cell volume percentage	Hæmoglobin grammes per cent
93	62.8	33.3	10.5
91	40.3	31.9	9.3
75	57.7	38.2	13.7
74	58.3	37.6	11.4
70	58.3	38.5	12.8
72	49.3	34.5	10.6
65	45.8	34.8	10.3
48	40.4	37.1	11.8
47	41.1	33.7	13.2
44	46.0	38.4	13.5
43	40.1	36.4	12.7
39	55.2	40.0	13.0
32	46.6	38.8	11.1
30	44.9	34.0	9.9
20	41.6	40.1	11.5
20	28.0	34.2	10.6

The blood sedimentation rate of nine boys living in the same colony and who appeared to be in perfect health and had no symptoms or signs suggestive of epidemic dropsy was estimated. These boys were selected at random.

TABLE III

The sedimentation rate and the cell volume in nine apparently healthy boys living in the same colony and who had no symptoms of epidemic dropsy

Number	Sedimentation (mm.) after 1 hour	Cell volume percentage
1	122	33.3
2	61	36.0
3	59	41.4
4	55	37.7
5	50	40.9
6	50	33.9
7	45	35.0
8	36	35.6
9	19	41.7

From the results (table III) it will be seen that the sedimentation rate of the blood is increased in all the nine boys. It is suggested that these boys who had no clinical evidence of epidemic dropsy were according to the results of the sedimentation test in a 'pre-epidemic-dropsy state'. These results suggest the value of this non-specific test, the sedimentation rate of red blood cells in indicating disease where other tests fail. The blood sedimentation test would be of value in epidemiological studies. Unfortunately, as no further cases developed it was not possible to investigate this point further. The value of the blood sedi-

mentation test in differential diagnosis is illustrated by the following example:—

A well-built non-Bengalee adult who had suffered from swelling of the feet for about three months was diagnosed clinically as suffering from epidemic dropsy. The patient stated that he did not use mustard oil in any form. The blood sedimentation rate was found to be within normal limits and on further examination the œdema was found to be of cardiac origin.

Investigations as to the factors concerned in this outbreak:—

(a) *Rice*.—Rice had been given twice daily throughout this outbreak, but was stopped in June when a number of cases had occurred. The samples available for examination in June 1939 were of healthy parboiled rice without any opacities in the grain and without any fungal attack.

(b) *Mustard oil*.—The mustard oil used was drawn from one source of supply. The seeds from which this oil was expressed were from one consignment of mustard seeds which had been received a year previously. The ration of oil was 2 ounces per day per boy. This oil gave a positive nitric acid test for argemone oil. The intensity of colour suggested that argemone oil was present in about 1 per cent concentration.

(c) Other foodstuffs were of good and varied quality and fresh vegetables and meat were supplied daily.

Early in July 1939 when there were 37 boys suffering from the disease, rice was omitted from the diet and the boys given bread (as *chapattis*), and three weeks later the use of mustard oil for cooking purposes was also stopped and clarified butter (or *ghee*) used. No further cases occurred. The affected boys examined a month later were found to be well. Unfortunately, owing to the popular belief that rice is mainly responsible for the causation of the disease, it was not possible to continue the use of rice. Cases however continued to occur even after rice had been stopped and it was not till the use of mustard oil was discontinued that the occurrence of fresh cases ceased.

Summary -

An outbreak of epidemic dropsy in a closed community of boys is described. Of the 242 inmates 37, or 15.2 per cent of the boys, developed epidemic dropsy. Of the 37 boys affected 17, or 46 per cent, had sarcoids.

The blood sedimentation rate, the fibrin nitrogen content, the cell volume and hæmoglobin percentage of 16 affected boys were determined.

THE ASCHHEIM-ZONDEK AND THE FRIEDMAN TESTS IN THE DIAGNOSIS OF THE LIFE AND DEATH OF A FÆTUS

By C. L. PASRICHA

MAJOR, I.M.S.

Professor of Bacteriology and Pathology

S. LAL

Assistant Research Worker

and

K. BANERJEE

Assistant Professor of Pathology

(from the Department of Bacteriology and Pathology,
School of Tropical Medicine, Calcutta)

ALTHOUGH a negative Aschheim-Zondek test (or the more rapid modification, the Friedman test) is not by itself diagnostic of fœtal death, a positive result with either of these tests is of value in indicating that the fœtus is alive. The following case illustrates an important application of these tests:—

A diagnosis of a dead fœtus was made in a woman aged 25 who was pregnant for about six months. This diagnosis was based on the inability to hear fœtal heart sounds and on the apparent cessation of growth of the uterus after three examinations carried out at three-weekly intervals. The woman who felt well and was active had not been informed of the suspected death of her child. She felt no fœtal movements and the repeated enquiries about the movements from her anxious husband led the young expectant mother to suspect that all was not perhaps well. The patient was advised that unless labour set in naturally within a short period labour should be induced. The Aschheim-Zondek and the Friedman tests were done with a specimen of her urine and gave positive reactions. The tests were done according to the methods advocated by Browne (1938). The methods are summarized below:—

(a) The Aschheim-Zondek test

1. Five female mice 3 to 4 weeks old and weighing 6 to 8 grammes each were injected subcutaneously in the buttock with slightly acidified urine. The injections were given twice daily for three days. Doses at each injection were:—

Mouse 1	0.2 c.cm.
" 2	0.25 "
" 3	0.3 "
" 4	0.3 "
" 5	0.5 "

2. The mice were killed at the end of 100 hours after the first injection.

3. The ovaries were enlarged, pinkish and contained small pin-point hæmorrhagic points (from 1 to 3 in each ovary). The hæmorrhagic points were readily seen by the naked eye. The test was positive in all the five mice.

(b) Friedman test

1. A virgin female rabbit 14 weeks old was used. For this test the rabbit must not be less than twelve weeks old.

2. Two intravenous injections, each of 6 c.cm. of the morning urine, were given daily for two days.

3. On the third day, i.e., 48 hours after the first injection, the animal was killed and the ovaries inspected. Large corpora hæmorrhagica were seen projecting on the surface of the ovaries. This constitutes a positive test.

For control purposes similar tests were done with specimens of urine from a pregnant woman known to have a live fœtus and from a woman who was not pregnant.

Discussion.—The Aschheim-Zondek and the Friedman tests for pregnancy were positive with the urine of the woman whose fœtus was thought to be dead and with the urine of the woman known to have a live fœtus. Both these tests were negative with the urine of a woman who was not pregnant. According to Browne (*loc. cit.*), the Aschheim-Zondek test is correct in 98 to 100 per cent of cases. This author states 'It seems to depend on the presence of living chorionic epithelium and may therefore be used as a test for death of the fœtus. Since, however, the chorionic epithelium survives for some time after the death of the fœtus, the test does not become negative for eight to twelve days after fœtal death has occurred; but if there has been gradual interference with the placental circulation prior to its complete cessation, such as occurs in placental infarction, it may become negative in three days'. Since the death of the fœtus had been suspected to have occurred more than two months prior to the time the tests were done, it was concluded that the fœtus was not dead. This opinion was supported by two x-ray pictures taken at four hours' interval. In the first picture the fœtus was seen lying with the head in the right iliac fossa with both the arms pointing downwards. In the next picture the position of the two arms had changed, one arm was pointing upwards by the side of the head and the other arm across the chest. There was no overlapping of the skull bones nor any marked curvature or angulation of the spine, nor any general crowding together of the skeleton.

The positive Aschheim-Zondek and Friedman tests supported by the x-ray pictures led to re-investigation of the history of the case. There had been some confusion as to the last menstrual period. The rest of the pregnancy was uneventful and the woman was delivered of a live child four months later.

Summary

The case is recorded in which on clinical examination the death of the fœtus was suspected. The Aschheim-Zondek and the

MALARIA IN CHOTA NAGPUR

By C. STRICKLAND, M.A., M.D.

(from the School of Tropical Medicine, Calcutta)

AN outbreak of malaria at Hazaribagh on the Chota Nagpur plateau in Bihar in a certain segregated community has led to the following report on what appear to be the important factors in the matter.

Fry (1912 and 1914) approached the subject from another direction, and showed that villages on the plateau have a comparatively low spleen-index (7 per cent in 528 children): the following records by the writer confirm his figures:—

Village	Number of children examined	SPLENOMEGALY INCIDENCE	
		Number	Percentage
Tatisilwai ..	40	7	17.5
Mandu ..	33	6	18.0

On the other hand he found that villages along the ghats* cutting the face of the plateau escarpment were intensely infected and he noted that two particular villages, Angarah and Bundkhela, situated at the top of the ghats but otherwise apparently quite similar to villages on the plateau were as highly infected as any he had found at the foot of the scarp, and they are notoriously malarious.

His findings are instructive, relating as they do to two areas of observation one of which can be regarded as a control of the other. In the two areas, the plateau and the ghats, only the physiography of the terrain varies. In both there are terraced rice-fields, though on the ghats the terracing is steeper. Over the plateau the stream flows more gently, so that surface run-off of storm-water is slower, but, on the other hand, as the land is at a higher altitude, seepage is more rapid and the water 'table' is lower. The communities are the same in each case, so there is no justification for regarding malaria as a social disease. Only physiographical factors differ.

As for differences in the climatic conditions, Fry's observations prove one very important point. This is, that upon the plateau, as at

Angarah, at an altitude of approximately 2,000 feet, the climatic conditions are not inhibitory to malariogenesis. One might of course have presumed this from the incidence of malaria in the Darjeeling foot-hills, where severe epidemics and a spleen index of 55 per cent and more have occurred at an altitude of about 2,500 feet, i.e., in a region where foot for foot the climate is cooler than on this peninsula plateau. Climatic inhibition then does not account for the relative freedom from malaria of the plateau in general*.

If then on the plateau climate is no bar to malariogenesis and malaria comparatively speaking is slight, what can be the reason for this? What can be the explanation of the ghats being so malarious, the plateau so non-malarious? As stated, only the physiography varies and this considerably. The village tanks, and other hold-ups of the surface-water, and the wells, are the same in both tracts, but the rice-fields are more steeply terraced on the ghats, the stream instead of flowing slowly over the plateau now runs fast down its rocky channel, and the further one descends the longer the period during which the streams flow, and the greater the amount of the spring water cropping out on to the surface. Even in the fair-weather season the stream runs fast down the ghat, although there are now numerous shallow pools along its course, whereas on the plateau the stream bed is largely sandy and discrete pools on its bed are relatively infrequent.

During the rains, in neither the plateau streams nor ghat streams are there many anophelines; they are scoured away. It is in the fair season that they survive, but then the mosquito-breeding places on the sandy riverbeds of the plateau streams are few and far between, as compared with the innumerable rocky pools, ideal for mosquito larvæ, that mark the courses of the ghat streams. A factor of importance in this matter must be the equability of the flow in the two types of stream; those on the plateau maintain an equable flow, on the ghat they are torrential, i.e., they swell with a storm and subside at its passing. Equability in the flow of a stream is an important factor in malariogenesis, a matter that will now be referred to, in relation to the influence of natural enemies.

The more equable and gentler the flow of water in a stream and the greater the accessibility

* 'Ghat' may mean either the length of the scarp or the approach to the plateau up a steep valley.

Friedman tests were positive and led to the revision of the clinical diagnosis. Eventually the woman gave birth to a live child.

REFERENCE

Browne, F. J. (1938). *The British Encyclopædia of Medical Practice*, Vol. X. Butterworth and Co. (Publishers), Ltd., London, p. 62.

* One may note here that there is a difference in the seasonal incidence of malaria in the two regions. In the Himalayan foot-hills at an altitude of 2,500 feet, and indeed round 2,000 feet, the incidence of malaria is vernal; autumn is too cold for malariogenesis there, while on the Chota Nagpur plateau on the other hand the incidence of malaria tends to the common plains type, i.e., autumnal, though it is definitely earlier than on the plains, as also is maximum mortality (Fry). That is what one would expect from the point of view of the cooler climate in its bearing upon the potential infectivity of the mosquito. At higher altitudes on the plateau, one should find an even earlier malarial incidence than in the villages recorded by Fry.

of the mosquito-breeding places to natural enemies, like fish, the greater will be the destruction of the mosquitoes. A torrent that is seoured out with great violence during a rain-storm and a little later is represented by a series of pools from which there is no surface flow at all is in an ideal condition for the production and full development of mosquitoes long before their natural enemies, such as fish, can be established therein.

Another factor in the matter may be more frequent, 'deviation' by domestic animals, on the plateau.

It is not along the sandy-bedded streams of the Chota Nagpur plateau only that one finds a comparative freedom from malaria. On the plains of Bengal too one notices along all the sandy-bedded rivers that one can recall to mind, e.g., the Damodar in Burdwan District, the Ajay and the Barakar also, the Subarnarekha in Midnapur, that they are characterized by healthy communities living along their banks.

Other things being equal one need not perhaps look for any other reason for the differential malaria incidence in the plateau villages and the ghat villages than those differential physical characters in the streams. When the rains stop, mosquito breeding starts, but to a much greater extent along the ghat streams, and that causes the autumnal epidemic.

From the cessation of the rains onwards more and more of the streamlets dry up as one ascends the ghats, so that by the end of the 'hot-weather' there is very little surface-water at all on the plateau and high up the ghats; there is much more in the streams and swamps at the foot of the hills. If then there is a high malaria rate in the villages at the top of the ghats it can only be derived from the stream in autumn and perhaps winter. Now if the fair-weather streamlets at the foot of the ghats run for such a longer period than those upon the ghats, then the villages in the former situation should be the more malarious, but, as was narrated above, that is not the case, and the reason for this is that in the lower situation the climate is too hot for the development of the malaria parasites, and, moreover as Fry says, the mosquitoes then die out*.

Different factors operate in the two zones to control infection in either during the hot weather. The autumn is the only season when there are mosquito-breeding places and mosquito production in both tracts, and a

* In the hot weather in the plains although the mosquito dies out because of the heat, and at the head of the ghats never comes into being because there is no water, yet it will be observed that in both tracts by the autumn it becomes prevalent enough to produce the annual epidemic. One has seen stated that in certain parts of Bengal pathogenic mosquitoes only start to breed in the autumn but then it is too late for malariogenesis. The above narrated facts, however, show that that argument is fallacious,

suitable temperature for development of the parasite.

With regard to the plateau itself one must repeat that, while the autumnal temperature is suitable for infection, eulieidigenesis is too scanty for it to be of any importance and that is the state of affairs that also pertains to all the big river-beds in Bengal.

One must consider, however, the possibility that the different physiography of the ghat streams leads them to support a different anopheline fauna, perhaps the streams having a more rapid surface run-off carry sweeter water and yield a different and perhaps more malariagenic anopheline fauna.

From this point of view Senior White and Das' (1938) observation in the Singhbhum District that the *funestus* group was perhaps solely responsible for the malaria there makes one suspect that it also occurs on the Chota Nagpur ghats, though here one goes to considerably higher altitudes than those observed by Senior White. Nevertheless, the writer has never found this species* in Chota Nagpur and Fry mentions that he did not find the adults of *funestus* ('*listoni*') in the highly-infected villages, when *culicifacies* and *jeyporiensis* were swarming, nor could he find larvæ of '*listoni*' on combing out the water of the rice-fields. The possibility of *funestus* races being responsible in the ghat villages is indeed quite hypothetical, and as it also has not been recorded from the streams on the plateau no differentiation in respect of this species or in fact of any other has been established.

At the same time Fry, like Senior White in Singhbhum, could not find those putatively infective species, *culicifacies* and *jeyporiensis*, infected. He examined 76, a sufficient number in a hyperendemic village to have yielded something positive if they had been culpable, unless the season was rather too early. The writer found *culicifacies* and *jeyporiensis* plentiful at Hazaribagh.

It may be noted that where the plateau and the ghats merge into one another intermediate grades of spleen-index are found, and whereas at Ramgarh the profile of the ghat stream (figure 1) flattens out, which, torrential though it be, does not partake of the full character of a ghat stream, the spleen-index is also intermediate in magnitude.

* The types of breeding places examined by the writer on the plateau and their mosquito fauna may be stated as follows, for record:—

Rice-fields under seepage water	<i>jeyporiensis</i> <i>nigerrimus</i> <i>pallidus</i> <i>annularis</i> <i>splendidus</i>
Stream-beds (nullahs)	.. <i>pallidus</i> <i>culicifacies</i> <i>jeyporiensis</i>
Bandhs (reservoirs)	.. <i>annularis</i>

The influence of *bandhs* (figures 2 and 3), as are called the reservoirs produced by damming up a line of surface drainage, may be here

Fig 1—Showing the Damodar river at Ramgarh

Fig. 2.

Fig. 3.

also mentioned. At Mandu there are two such *bandhs* overgrown with aquatic vegetation (figure 3), such as would in certain other

parts of India make the politicians talk vociferously about the iniquity of a Government allowing such a thing and call to the colours every able-bodied citizen to clear the nuisance. Yet the spleen-index of this place was about 18 per cent, and that it was as high as this was possibly due to it not being very far from a small ghat stream. Mosquito larvae were not easily found in these *bandhs*.

They hold perennial water and if the non-perennial stream at the head of a ghat be highly malarigenic in the autumn, why should not these perennial *bandhs* be highly malarigenic?

If there be no difference in the species of anophelines they support, the reason may be ascribed to the existence of 'natural enemies' in these collections of water.

Finally, it is interesting to note that in this part of the country, man for the purposes of his livelihood has sometimes unwittingly carried out anti-malarial measures. Where a stream has not too high a gradient, it has been in many places filled in up to the level of the adjoining *padi* fields so as to afford a slightly larger area of rice-growing land. Powerful *bandhs* of rock across the stream *nullah* are necessary where this is done, otherwise the subsoil flux rapidly washes away the earth-filling. While this lasts it certainly minimizes the dangers that lie in the streams. Except for this sort of thing, the conclusions reached above indicate for permanent control work the training of the hill streams, or better still the damming up of lines of drainage to form permanent reservoirs, such as are shown in figures 2 and 3.

Fig. 4—The potter, helped by two coolies, turns out 200 pipes daily.

On land where selected communities are settled a comparatively low endemic-index may have serious consequences and therefore mention may be made here of the use of sub-soil drainage by the Rev. Father Turkenburg at St. Stanislaus College, Hazaribagh. He has written an account of the material and technique employed (1938) and figure 4 illustrates the pottery produced by his workmen at such

A SIMPLE TECHNIQUE OF GIVING INTRAVENOUS QUININE WITH SALINE

By R. K. DE, L.M.F., D.T.M.

Assistant Medical Officer, Talap Tea Estate,
Talap P. O., Assam

IN tea-garden practice, we frequently encounter algid cases of malaria, both in adults

(Continued from previous page)

a low cost that this system of drainage is here brought within reach of a much wider circle of people than those whom it has been used to protect.

Summary

The Chota Nagpur plateau is mildly malarious. The villages at the head of the ghats, and also those along them and at their foot are severely malarious.

As the climate on the plateau is optimal for malaria-genesis, it is surmised that it is the physical conditions of the terrain, particularly the equability in the flow of the gentle streams and the operations of natural foes of the mosquitoes, or deviation by domestic animals, that inhibit a too dangerous culicidigenesis. This consideration also applies to certain communities living beside big river-beds in Bengal and to the Chota Nagpur villages in which *bandhs* or reservoirs of water have been made.

The streams at the head of the ghats mostly dry up in the hot weather and therefore the hyperendemicity there is due to mosquito breeding in the autumn.

The streams at the foot of the ghats flow for longer periods, but this advantage to culicidigenesis is offset on the malaria account by the excessive heat of the plains during the hot weather inhibiting the development of the malaria parasite.

Malaria control should be mainly carried out by creating series of reservoirs along the courses of the malariagenic streams so as to drown the mosquito haunts. Fish ladders could be provided at the same time and so some economic advantage could be gained from the proposed measure.

Acknowledgment

The writer is much obliged to the Rev. Father Turkenburg at Hazaribagh for his help in enabling him to carry out his investigations as far as Hazaribagh was concerned.

and children. Every choleraic diarrhoea case that comes is looked upon with suspicion as to the possibility of the case being due to malaria. In such cases the microscope is the only thing that helps us in making a rapid diagnosis.

The technique.—When the case has been diagnosed as one of the choleraic type of malaria, saline infusion is begun, either by direct vein puncture or by opening a vein. Then I take in a syringe the desired amount of quinine dissolved in one or two cubic centimetres of distilled water and while the saline flows on, inject the quinine into the saline solution through the rubber tube that connects the saline funnel and the needle. The rubber tube is taken as a vein, sterilized with spirit and punctured. The quinine solution is given very slowly so that it is well diluted with saline, and this eliminates shock.

This method of giving intravenous quinine by injection into the rubber tube has the following advantages:—

(1) Most of the cases come so late that saline infusion has to be undertaken at once before anything can be done in the way of laboratory diagnosis. In such cases, I generally take a blood slide first and begin saline injection and, by the time it is prepared and the administration begun, the blood slide has been examined; if it is 'positive', the quinine is given by the above technique. Hence further puncture or opening of a vein is avoided.

(2) Exact amount of quinine can be given as desired or necessary. If the quinine is mixed up with saline, there is chance of loss of a certain percentage of quinine, as the whole quantity of saline taken for infusion may not be required and also some cases react badly after a few ounces of saline.

(3) The most important advantage is that quinine can be stopped at the slightest possible sign of quinine shock and any intravenous circulatory and respiratory stimulant can at once be given by this method. My procedure in bad cases of choleraic malaria is that I first give 0.5 to 1 c.cm. of adrenaline chloride by this method and then I give quinine. This prevents any possible occurrence of shock from quinine.

By this technique I do not deprecate the other valuable techniques nor do I claim something new, as it may be known to many. I send this note for publication because there may be some who will find some interest in it. Also I think that any technique, however simple and negligible it may be, should be recorded.

[Note.—We note what the writer says on this point, but we still consider that much the same result could be achieved by pouring the quinine into the tank with a small amount of saline and adding the rest of the saline when this is almost exhausted.—EDITOR, I. M. G.]

SUGGESTION FOR A NEW TYPE OF TUBE FOR BACTERIOLOGICAL CULTURES.

By T. V. SWAMY, M.B., B.S.

Assistant Lecturer, Pathology Department, Medical College, Rangoon

THE ordinary test-tubes as holders for solid culture media in bacteriological work have been in use fairly successfully now for a long time. McCartney suggested, as late as 1933, the ordinary screw-capped medical 'flat' as a more efficient substitute for the test-tube.

For the last two years, we have been using these 'flats' for cultural work both in this department and in the General Hospital

bacteriological laboratory and from this short experience, I consider there is scope for a further improvement in this type of container.

The usual 'flat' is made up of an oblong body and a narrow neck with the threads for fitting the metal cap. The disadvantages in this form of 'flat', to my mind, are that the neck is a little too narrow for utilizing the whole of the culturable surface when a loop spreader is used. This means a waste of a part of the medium. I believe, a larger bore of the neck would overcome this defect. Again, the corners of the oblong medical 'flat' being as they are abruptly angular prevent a good visibility of certain parts of the culture. This can be got over possibly by converting the angularities into two gradual curvatures on opposite sides of the main flat surfaces. This idea occurred to me

THE USE OF THE DOMESTIC FOWL FOR THE PREPARATION OF DIAGNOSTIC ANTISERA

By C. L. PASRICHA

MAJOR, I.M.S.

M. N. LAHIRI

and

B. M. PAUL

(from the Department of Bacteriology and Pathology, School of Tropical Medicine, Calcutta)

THE domestic fowl is frequently used as a laboratory animal, but as far as we are aware it has not been used for the preparation of diagnostic sera. Owing to the difficulty in both

(Continued from previous column)

after seeing a glass holder of a common make of tooth brush.

This container, if provided with a screw-cap end of a sufficient diameter, would make an ideal media holder. Indeed, a container of this kind could very well be used instead of the Petri dish which has some obvious disadvantages. Owing to the larger width of the mouth suggested, it would be possible to introduce through it the usual angular glass spreader for inoculation just as in a Petri dish.

The above diagrams with the explanatory foot-notes will clarify the advantages of the suggested modifications.

McCartney, J. E. (1933). *Lancet*, ii, p. 433.

obtaining and maintaining in Calcutta an adequate stock of rabbits, the animal almost universally employed for raising high-titre sera, it was thought desirable to test the agglutino-genie response in fowls after the injection of the commonly-employed bacterial antigens. Medium-sized domestic fowls (weighing $1\frac{1}{4}$ to $1\frac{1}{2}$ pounds), which are obtainable in large numbers in the local markets, were used and the amount of antigen injected was half the amount usually injected into a rabbit. The intervals between injections and the number of injections were similar to those employed in a rabbit. Seven to ten days after the last injection the fowl is bled from the wing vein and 10 to 15 c.cm. of blood can be collected from the vein of a fowl without causing any appreciable harm to the bird. If desired the blood can be collected by heart puncture or the animal 'bled out'. Satisfactory high-titre sera were obtained for *Bacterium typhosum*, *Bact. shigæ*, *Bact. flexneri* and *Vibrio cholerae*. As an illustration the sera obtained after injections of dried 'O' antigens of standard Inaba and Ogawa vibrios were found to give the following agglutination results:—

The results of agglutination test with cholera high-titre sera raised in domestic fowls and in rabbits

Serum	AGGLUTINATION WITH <i>Vibrio cholerae</i>	
	Inaba type	Ogawa type
A. Fowl serum prepared with		
I. Inaba O ..	1,500 *	0
II. Ogawa O ..	0	2,500
B. Rabbit serum prepared with		
I. Inaba O ..	1,000 *	0
II. Ogawa O ..	0	2,500

* After absorption with Ogawa strain to obtain a differential serum.

0 = No agglutination in 1 in 100 dilution of the serum.

The domestic fowl is valuable in tests for potency of therapeutic vaccines. The amount of vaccine injected into each fowl is one-quarter of the total human dose recommended by the manufacturer and it is injected in a series of three graded doses at intervals of five days. The serum of each bird is examined for the presence of specific agglutinins before the inoculation of vaccine and again ten days after the last dose. If the antigenic response is poor further injections can be given to the same bird. In order to avoid the possibility of poor antigenic response due to inherent insusceptibility of any particular animal, it is advisable to use more than one animal.

The domestic fowl is not only readily available in large numbers in the local markets but

(Continued at foot of next column)

THE VIABILITY OF *VIBRIO CHOLERA* IN NATURAL WATERS

By M. N. LAHIRI

P. C. DAS

and

K. S. MALIK

(From the Cholera Bacteriological Enquiry, Indian Research Fund Association, School of Tropical Medicine, Calcutta)

As water is one of the most important vehicles of infection in cholera, the viability of the cholera vibrio in natural waters has attracted the attention of a number of cholera workers. Workers who have examined the viability of *Vibrio cholerae* in water are agreed that whereas the vibrio can live for a short time in untreated natural waters, it survives for longer periods in samples that had been previously boiled. Hankin (1896) attributed the bactericidal effect to the acid reaction of the river waters. d'Herelle (1926) suggested that the disappearance of vibrios from natural waters was due to the presence of specific cholera phage present in these waters. Later, experimental data of d'Herelle, Malone and Lahiri (1930) did not support this opinion. These workers examined the viability of cholera vibrios in waters collected from various sources including one sample of hill water, and recorded a maximum viability of 48 hours except in one sample of well water in which agglutinable vibrios survived for three days. In view of the recent, more exact serological identification of the cholera vibrio using standard O-agglutinating sera, it was

(Continued from previous column)

is cheaper than the rabbit. A medium-sized fowl costs about 7 annas (about 8 pence) each in Calcutta and about half that price up-country. The price of a medium-sized rabbit is four to five times the price of a fowl. A number of birds can be kept in a small fowl pen and their upkeep requires no elaborate arrangements such as are necessary in the maintenance of a healthy stock of rabbits.

The only difficulty experienced with these birds is that when a batch is purchased a certain number die, but, if the birds are used after having been kept under observation for about a fortnight, there is very little danger of losing experimental birds.

The birds are conveniently marked by fixing numbered rings on their legs.

An additional advantage of the use of these birds is that blood agar medium made with the blood of these birds supports the growth of such fastidious organism as *Neisseria meningitidis*. Sacrificed birds can be utilized for the preparation of digest broth (best made from the pounded bones and muscle), and any eggs laid in the fowl-run are incubated and subsequently used for virus work.

thought desirable to retest the viability of standard strains of vibrios in natural waters.

The samples of water were collected from surface tanks situated in certain parts of Calcutta where the disease is most prevalent, from the river Hooghly and from certain other sources. Four litres of water were collected from each source in a sterile stoppered bottle. Each sample of water was arranged in four flasks:— (a) raw untreated, (b) raw and autoclaved, (c) filtered through L³ candle, and (d) filtered through L³ candle and autoclaved. A saline suspension (from a young agar growth) containing approximately 1,000 millions of a freshly-isolated cholera vibrio (Inaba type) was added to each flask. The flasks were kept in a cupboard at room temperature and were examined every hour for the first six hours and then every 24 hours until vibrios were no longer recovered from the sample. A sample was considered to be free from vibrios when three successive examinations (using 100 c.cm. of the water as the inoculum) yielded negative results. The isolation of vibrios was carried out on bile-salt agar plates and on Aronson's medium after enhancement in peptone water. Vibrios were not present in uninoculated samples of these

used in the test were not found in any of the samples tested.

TABLE I

The viability of V. cholerae in samples of water from specified sources

Source of water	RAW		FILTERED THROUGH L ³ CANDLE	
	Untreated	Auto-claved	Raw	Auto-claved
Hill (spring) water.	1 hr.	18 hrs.	Not done	Not done

A PRELIMINARY REPORT ON THE MEDICO-LEGAL VALUE OF THE FINDING OF BLOOD ON NAIL PARINGS

By D. P. LAMBERT, M.D., D.T.M. & H. (Univ. Edin.)

MAJOR, I.M.S.

Civil Surgeon, Meerut

GIVING evidence recently before the Lahore High Court, the chemical examiner for the Punjab stated that in his opinion the finding of human blood on the nail parings of an accused person had 'Absolutely no medico-legal value whatsoever'. In support of this opinion he gave a short list of some possible sources of

(Continued from previous page)

The results (table III) show that there is an increase in the albuminoid nitrogen content of the water when the sample of water is autoclaved. It is suggested that this increase of nitrogen is due to the hydrolysis of the finely suspended organic matter in the water. There is an increase in autoclaved water in the food material available for the growth of vibrios.

It will be seen that *Vibrio cholerae* does not survive long in natural waters. In spring water it dies out in less than two hours and its longest duration in untreated natural waters is 72 hours. In autoclaved samples the viability is considerably increased.

In natural waters that have been rendered bacteria free by filtration through a Pasteur-Chamberland candle, the viability is increased and when such a sample is autoclaved the vibrio is capable of surviving for a longer period.

Conclusions and Summary

(1) The viability of a freshly isolated strain of *V. cholerae* in natural waters has been examined.

(2) The viability of *V. cholerae* in samples of waters that had not been treated in any way was found to vary from one hour in samples of hill water to 72 hours in water collected from certain tanks. These tank waters were found to contain a considerable amount of organic matter and to have a high salt content.

(3) The viability of *V. cholerae* is considerably increased in autoclaved samples. It is suggested that the increase in viability is due partly to the increase in the available food supply in the autoclaved water which results from the break-down of the suspended organic matter.

(4) Choleraphage was not found in any of the samples of water tested.

innocent contamination, and implied that such contamination was so usual as to be almost a normal finding. He also stated that it was 'most unlikely' that blood could be detected on the nail parings of a man accustomed to wash regularly, twenty-seven days after his hands had been stained by blood [The *Statesman* (Northern India Edition), 28th November, 1938, p. 14]. After hearing this evidence the High Court ruled that 'An end will now be put to nail paring evidence in this Province'.

In view of this ruling it seemed important to verify these statements by experiment. After testing the sensitivity of the reagents, I examined the nail parings of forty under-trial prisoners and of twenty convicted prisoners from Meerut District Jail. The parings were taken by the jail barber using his ordinary instruments and without any special precautions against contamination. Of the 600 separate nail parings so obtained three gave a positive reaction, and six gave a positive trace with the benzidine test. The remaining 591 were all negative. These specimens were received in bulk, so it is impossible to say whether the positively reacting nails all came from one person or from nine separate persons.

The benzidine test which was used throughout these experiments is very sensitive, but it is not a specific test for blood. If blood is present the test will detect it, even in extreme dilution, but a positive reaction is not a certain proof of the presence of blood, still less of human blood. These limitations of the test should be constantly borne in mind in interpreting the results.

The nails of ten hospital patients who had either open wounds or a free discharge of blood from some part of the body were next examined. It was impossible to be certain that these men had had their nails contaminated with blood, but it seemed very likely. The parings were made with ordinary hospital scissors, clean but not specially cleaned, and no unusual precautions were taken in cutting. The results of examining these nails are shown in the table below.

Compared with the results of the jail series the difference is striking. Some light is also thrown on the period up to which blood may persist beneath the nails. Assuming that no gross contamination took place after admission to hospital, blood persisted under the nails of these persons for an average period of 24 days, with a maximum period, disregarding traces, of 35 days. All these patients washed regularly, but none used soap, nail-brush, or any refinement of manicure.

As a control series I examined the nails of the remaining 24 hospital patients. Twelve sets of nail parings were completely negative. Eight sets showed a positive trace on one nail only. One set showed two positive traces. Of the remaining three patients one gave one positive reaction and one a trace. This man had

persistently tampered with his dressings after operation. The second gave two entirely unexplained positive reactions; and the third, who had had one nail cut to the quick on paring, gave a strongly positive reaction on that nail and a positive trace on the next. These results too contrast with those of the first group,

that a person may contaminate his nails with his own blood in many ways; but contamination with blood of a group other than his own would require a great deal more explanation. In this type of investigation blood grouping should never be omitted; otherwise valuable evidence may be lost.

TABLE

Case number	Source of bleeding	Days since admission to hospital	RESULTS OF THE BENZIDINE TEST		
			Strongly positive	Positive	Trace
1	Open wound	14	..	3	4
2	Bleeding ulcer	22	..	2	..
3	Bleeding dysentery	1	..	6	..
4	Open wound	1	1	5	..
5	Bleeding ulcer	39	2
6	Open wound	91	1
7	Open wound	9	..	2	5
8	Open wound	7	1	2	7
9	Open wound	35	..	3	2
10	Hæmoptysis	24	..	4	2

particularly if traces are disregarded. If contamination with blood is likely to occur anywhere it is likely to occur in an Indian District Hospital, and the results suggest that accidental contamination is not likely to amount to more than a trace, and that only on one or two nails.

Another experiment was made to find out the extent to which blood-stained scissors were likely to contaminate the nails they pared. Hospital scissors were smeared with blood and the blood was allowed to dry on. The scissors were then roughly washed and mopped dry. They were not polished or specially cleaned. After this treatment the scissors themselves gave a positive trace reaction, but nails cut with these scissors remained negative. This experiment was repeated several times with consistent results. If ordinarily clean scissors are used, and reasonable care taken in paring, it seems unlikely that serious contamination can arise from this source.

In his statement before the High Court, the chemical examiner made no reference to the subject of blood grouping. It is conceivable

I would re-emphasize the preliminary nature of these experiments, and again draw attention to the limitations of the benzidine test; but they strongly suggest that contamination of the nails with blood is neither a common nor a usual finding, and that every contamination of many nails is only likely to occur by contact with shed blood. The finding of blood on an accused's nail parings is certainly not conclusive evidence of guilt; but it is equally unscientific to say that such evidence is of no value whatsoever. The court will decide in each case what weight the scientific evidence will have.

It is very desirable that this subject should be re-investigated on a larger scale, using spectroscopic and precipitin methods. The ideal place for such a research would be a well-equipped medico-legal institute, the want of which provision greatly handicaps the administration of justice in India.

I have pleasure in acknowledging the courtesy of the Inspector-General of Civil Hospitals, U. P., and the Chief Justice of the High Court, Lahore, in permitting me to publish this paper.

A Mirror of Hospital Practice

ACUTE MEDIASTINAL EMPHYSEMA WITH GENERALIZED EMPHYSEMA

By F. A. B. SHEPPARD, F.R.C.S. (Edin.)

CAPTAIN, I.M.S.

District Medical Officer, Madura

ACUTE mediastinal emphysema is probably a common sequel to severe crushing injuries of the chest, but as it is frequently complicated by

other intra-thoracic damage it is not often that such cases are presented for treatment. In itself the condition calls for urgent surgical intervention as with each breath taken more air is forced into the relatively closed and restricted space of the mediastinum. As the blood returns to the heart from the lungs and the systemic circulation bears the brunt of the compression it is not surprising that signs of cardiac failure

and respiratory distress soon become obvious. To these effects are added, of course, those of surgical shock. If allowed to persist for any time the pressure of air in the mediastinum may burst through one or both pleural cavities with the production of a tension pneumothorax. It is of course always possible that with any severe crush of the chest, both a mediastinal emphysema and a tension pneumothorax may occur simultaneously, the symptoms then being correspondingly severe. Sauerbruch (Sauerbruch and O'Shaughnessy, 1937) states that the accident may also follow attempts at artificial pneumothorax where the needle has been inadvertently introduced into a portion of the lung adherent to the chest wall.

In the case reported below, it is interesting to observe that the injury appears to have given rise to a valvular defect in one of the root bronchi or in the lower trachea, with the result that while air was satisfactorily inspired, there was considerable escape into the tissues on expiration.

Simple opening of the space of Burns, as usually advised, cannot suffice since the deeper layer of fascia attached to the posterior surface of the manubrium sterni must be opened for adequate decompression of the mediastinum to occur.

Notes of case recorded

N., Hindu, aged 4 years, the son of a coolie, was admitted to hospital at 6.45 p.m. on 6th December, 1937, with a history of having been run over by a partially-loaded double bullock cart five hours before. Although it is difficult to believe that such an accident could occur without killing the child the parents persisted in the statement that the child had been climbing up the wheel of the cart, when the bullocks started to move, that he fell down and the right wheel had passed over his chest.

On examination the child was restless and in a desperate condition, with short rapid and grunting respirations. The whole body with the exception of the lower limbs was so extremely emphysematous that the bones of the chest and skull could not be clearly felt. The skin was shining except for the face and neck which were somewhat cyanotic and the eyes could not be seen because of the emphysema. The scrotum was enormously ballooned. There was an abrasion of the skin across the right half of the chest at the nipple line, but it was not possible to determine any fracture of ribs or sternum.

Respirations were 60 to the minute and the pulse could not be felt at the wrist. On auscultation, the heart did not appear to be displaced but the beat was extremely rapid. It was not possible to ascertain whether air was entering both lungs. The child's condition was so grave that examination was necessarily very hasty and no time could be lost by taking an x-ray picture.

Operation.—To exclude the presence of tension pneumothorax both pleural spaces were punctured with a pneumothorax needle. The pressure was negative on each side.

The root of the neck was then infiltrated with 0.5 per cent novocain and a low collar incision was made through skin, platysma and deep fascia. The sternomastoid attachments were defined and the mediastinum opened by finger dissection behind the manubrium sterni. The result was dramatic. Air immediately gushed out and was seen to escape with each expiration. Hæmostasis was secured and the wound was loosely covered with gauze. The effect on

the child was no less dramatic and he became calm and quiet and soon fell asleep. The extremities were wrapped in cotton-wool and bandaged and the child returned to the ward.

An x-ray photograph, taken immediately after the operation, revealed simple fracture of the second and third right ribs.

The generalized emphysema diminished considerably by 10th December, but did not completely subside until after another few days.

Air continued to escape from the wound for four days. The wound was allowed to close by granulation and the child was discharged cured on 19th January, 1938.

AN UNUSUAL CASE OF CUTANEOUS AMOEBIC ULCERATION AROUND THE ANUS

By R. V. RAJAM, M.B., M.S., M.R.C.P.

Venereal Specialist, General Hospital, Madras
and

P. N. RANGIAH, M.B., B.S.

Honorary Assistant Medical Officer, Venereal
Department, General Hospital, Madras

CRAIG (1934), quoting James' figures, points out in his treatise on amœbiasis and amœbic dysentery that 10 per cent of hospital cases in India, examined for *Entamoeba histolytica*, were positive for the tissue parasite. Despite such a common incidence of the infestation and the well-established fact of the parasite being a tissue invader, it is surprising how few cases of cutaneous amœbiasis occur or are recorded in current literature.

Modern textbooks on tropical diseases describe at length amœbic hepatitis and other complications of amœbic dysentery such as brain abscess and pulmonary amœbiasis; but cutaneous amœbiasis, particularly around the anus, has found little emphasis.

According to Craig, lesions of the skin produced by *Entamoeba histolytica* have been reported by Nasse, Carini, Daghorn and Heyman, Heyman and Ricon, Engman and Heithaus, Heimburger, van Hoof, Cole and Heidman, Engman and Meleney, Kouri, Bolanos and Fuentes and Ngai and Frazier.

Manson-Bahr (1938) reported a case of amœbic ulceration round a colostomy wound.

The latest case reported was by Gabriel (1939) in which it appears no amœbæ or cysts were demonstrated in the scrapings from the ulcers or colostomy wound.

Engman and Meleney reviewing the ætiology of cutaneous amœbiasis showed that skin ulceration may occur :—

- (i) About the anus in cases of amœbic colitis or dysentery.
- (ii) Subsequent to drainage of an amœbic abscess of the liver.
- (iii) Drainage of a lesion of the appendix or of the large intestine, or

(iv) without any direct connection with the viscera.

The comparative rarity of this complication of amœbiasis and the ease with which the condition may be mistaken for ano-rectal lymphopathia venereum prompt us to report this case.

Fig 1—Lower Power—Note the numerous amœbæ surrounded by granulation tissue

The patient, a male, aged 40 years, came to the General Hospital on 15th August, 1938, complaining of passing blood and mucus per rectum and ulceration around the anus for about six months. As he gave a history of having suffered from bilateral bubo, he was referred to the venereal department as a case of suspected ano-rectal lymphopathia venereum.

Fig. 2—The same field but under the high power showing the amœbæ

Physical examination revealed no active lesion on the genitalia but there were scars of past buboes in both groins. There was extensive chronic indolent perianal ulceration with irregularly radiating indurated scars almost obliterating the anal orifice. Digital examination showed a tight stricture of the anal orifice and with difficulty the finger could be passed through the stricture. The mucous membrane of the rectum appeared normal to the feel except that the examining finger was stained with blood and mucus. A sigmoidoscopic examination was refused. Barium enema did

not reveal any stricture further up the rectum and colon.

In view of the past history of bilateral bubo and the present clinical condition a Froe's intradermal test was performed with negative result. A section from the ulcer was sent to the pathologist, Medical College, and the report was as follows:—

'Section shows ulceration and necrosis of the stratified epithelium with evidence of chronic inflammation. In the neighbourhood of the ulcer are seen numerous amœbæ.'

Fig 3—Photomicrograph showing numerous *E. histolytica* with nuclei in them; a few show red cells within (1/12th power).

Fig 4—Photograph showing ulceration around the anus.

The smear from the rectum also showed a large number of *Entamoeba histolytica*. The patient was treated for amœbiasis with a course of emetine hydrochloride injections followed by emetine bismuth iodide orally.

The ulceration rapidly healed and the discharge of pus and blood from the rectum ceased. A colostomy was suggested for the tight stricture but was refused. The patient could not be followed up as he defaulted owing to fear of operation.

We are thankful to the Professor of Pathology and his staff for the pathological report and photomicrographs; and to the Superintendent, Barnard Institute of Radiology, and his staff for the clinical photograph.

CEREBRO-SPINAL FLUID FINDINGS IN A CASE OF MENINGOCOCCAL MENINGITIS

By M. G. PRADHAN, Ph.D. (Lond.), D.T.M. & H. (Eng.)
Honorary Bacteriologist, Goculdas Tejpal Hospital, Bombay

THE examination of a sample of cerebro-spinal fluid gave the following results:—

General examination (naked eye).—

Appearance	..	Opalescent.
Deposit	..	Absent.
Coagulum	..	A fine fibrinous coagulum present after two hours.

Chemical examination.—

Total proteins	..	Increased (qualitative).
Globulin	..	Pandy's test—positive. Nonne-Apelt phase I—positive.
Sugar	..	Present, diminished (qualitative).
Chlorides	..	730 mgm. per 100 c.cm.

Cytological examination.—

Total number of cells.	220 per c.mm.
Differential count	Polymorphs.—40 per cent. Mononuclears.—60 per cent.

Bacteriological examination (centrifuged deposit examined stained).—

Gram's stain	..	No micro-organisms seen in smears.
Ziehl-Neelsen stain	..	No acid-fast bacilli found even after prolonged search.

(The fluid was incubated at 37°C. for 12 hours, and centrifuged deposit was again examined for micro-organisms.)

Gram's stain .. Gram-negative diplococci present.

The deposit was plated on ascitic agar and a pure culture of meningococci was obtained.

Levinson's differential test.—

Levinson's differential precipitation test gave a positive result for tuberculous meningitis.

Comments.—In the absence of a direct demonstration of the infecting micro-organism in the smears made from the centrifuged deposit of the fluid, other findings such as the number and the type of cells, presence or absence of sugar, and the quantitative estimation of chlorides help to determine the diagnosis in a case of meningitis.

Thus we say that meningococcal meningitis gives rise to increased polymorphonuclear cells and tuberculous meningitis to increased lymphocytes. This, however, seems to depend entirely on the intensity of the stimulus given by the infecting micro-organism and the stage of the disease at which the fluid is obtained. Thus if a case of meningococcal meningitis is seen early enough, before the infecting organism has multiplied sufficiently to cause a polymorphonuclear response, one may, as in the present case, find a predominance of lymphocytes. (The fluid in the present case was obtained on the very first day when the patient complained of fever and headache). Alternatively, I have seen a pure polymorphonuclear exudate in a case of tuberculous meningitis following acute miliary tuberculosis. Similarly the character of the coagulum also will depend upon the number of cells and the amount of fibrin present in the fluid.

In this case the quantitative estimation of chlorides alone helped diagnosis, and treatment for meningococcal meningitis was instituted on the strength of the chloride finding alone, without waiting for further bacteriological examination. An examination of the patient's blood film revealed a polymorphonuclear leucocytosis.

Subsequently, on incubation and further culture, meningococcus was obtained from the fluid. The patient also made a remarkable recovery on specific antiserum combined with M. & B. 693.

Levinson's differential precipitation test was done out of academic interest and to my surprise it was found positive for tuberculous meningitis. The reaction is said to depend on the electrical charge of the exudate which is different for meningococcal and tuberculous meningitis, which gives rise to different quantities of precipitates. Here too it may be pointed out that the electrical charge, the type, and the amount of precipitate will depend entirely on the type of cells forming the exudate. On this account it is suggested that the test is no more specific than the differential count of the fluid.

A CASE OF UNTREATED TRAUMATIC SPONDYLOLISTHESIS OF THE THIRD CERVICAL VERTEBRA

By M. G. KINI, M.C., M.B., M.Ch. (Orth.), F.R.C.S.E.
Surgeon

and

P. KESAVASWAMI
Radiologist

King George Hospital, Vizagapatam (S. India)

FRACTURES and dislocations of cervical vertebrae have been recognized since the earliest history of medicine. The first authentic description of this kind of injury was found in the Edwin-Smith Papyrus (1600 B.C.). Hippocrates described this condition and advocated treatment by extension in the recumbent position. Later writers described these injuries and were

of opinion that they were always serious and ended fatally. Henry Cline (1814) was the first to advocate operative interference in cases of this fracture. With the advent of radiography the treatment of this condition has changed; the closed method of reduction with good result is practised by extension, manipulation and fixation. Operative interference is advocated in cases which have come late, without any treatment, for relief of pain.

A male, aged 45 years, was seen in the out-patient department in 1935 for stiffness of the neck of nine months' duration. He gave a history that he fell on his neck losing his balance while rocking in a chair, hitting his head against the door sill. He was unconscious for half an hour. He had no control over his upper and lower limbs for 20 days. For 40 days he could not move his head. He did not give a clear history of his bladder or rectum control but said he had had no trouble from the time of the accident.

Fig. 1.

Fig. 2.

Photographs showing the deformity.

On examination, movements at the atlanto-occipital and atlanto-axial joints were found to be normal.

Fig. 3.—X-ray picture showing the dislocation of the body of the 3rd cervical vertebra forwards with the lamina remaining *in situ*.

Forward flexion was possible without pain and the chin touched the sternum. Extension was limited and painful. Lateral flexion was possible but limited. Marked prominence of the spine of the third cervical vertebra was seen. There were no radiating pains along the course of any of the cervical nerves, no weakness of the muscles of the extremities, and sensation in upper limbs was normal. In the lower limbs epicritic sensation was lost on the dorsum of the feet over the metatarsals, knee jerk was exaggerated on left side and Babinski reflex was flexor in response in both feet. He had normal control over

bladder and rectum. X-rays showed forward dislocation of the third cervical vertebra with fracture of the lamina from the body.

This patient is a Sadhu and wanders from place to place and refused any type of surgical

interference for fixing the spine. But the following points are noteworthy :—

Fracture-dislocations of the third cervical vertebra are generally considered serious because of the paralysis of the diaphragm which is associated with this fracture-dislocation. More than 75 per cent of cases are supposed to die from respiratory failure and hypostatic pneumonia or later from bladder and kidney infection and bed sores. The injury occurred as a result of over-flexion of the neck as a result of a fall from a rocking chair when it rocked back too far. He complains of nothing except slight rigidity.

The non-involvement of the cord in this region is surprising in spite of the fact it is a fracture-dislocation. This is explained by the x-ray which shows the body had slipped forward and the lamina had remained *in situ*, a case resembling spondylolisthesis due to trauma.

A CLAY TRUSS FOR INGUINAL HERNIA

By RAI BAHADUR CHHAGAN NATH

Assistant Surgeon, Medical Officer, In-charge
Lansdowne Hospital, Udaipur

A PATIENT from a rural area, aged 45, was admitted for right inguinal hernia. He had been suffering from this for many years, and to minimize his disability he made himself a truss. The truss was a rectangular

block about 6 inches long and 3 inches wide made of clay, with holes in the corners, and in the centre of the block was a peg about an inch long. He used to introduce this peg into the inguinal ring and tie the truss on by a string run through the holes and round his hips and he was able to perform his ordinary work.

The patient was operated on and left the hospital cured, leaving the truss with us.

TREATMENT OF TWO CASES OF ACUTE MENINGITIS (PNEUMOCOCCAL INFECTION) BY M. & B. 693

By MEHR SINGH CHAWLA, L.M.P.
Borstal Institution, Lahore

THE following two cases of acute pneumococcal meningitis which were treated successfully by the use of M. & B. 693 are recorded on account of their immense significance, as pneumococcal meningitis has heretofore been almost always fatal.

1. The first case was a boy aged 14 years residing in a densely populated area of Lahore. On the morning of 12th February last after severe headache and vomiting he developed acute cerebral symptoms in the form of a fit resembling an epileptic fit accompanied by rise of temperature to 103.4°F. The case was first considered to be cerebral malaria and was treated with atabrin on that day. But the symptoms persisted and the patient was restless during the night. On the next morning he had severe convulsions like those of the previous day and his neck was noticed to be retracted while the limbs and trunk were rigid. Kernig's sign was present. The patient was delirious and the temperature remained at 103.2°F. Lumbar puncture was done and the fluid was found to be turbid and under pressure. The fluid was examined by the bacteriologist to the Mayo Hospital and revealed the presence of many Gram-positive diplococci morphologically indistinguishable from pneumococci and also many pus cells. The treatment with M. & B. 693 was commenced at once, i.e., on 13th February at 11-0 a.m. Three tablets of M. & B. 693 were given by mouth along with an intramuscular injection 2.5 c.cm. of M. & B. 693 emulsion.

On the same day at 5-0 p.m. three more tablets of M. & B. 693 were given. On the 14th, 15th and 16th of February, two tablets were given *t.d.s.* along with one intramuscular injection of 2.5 c.cm. M. & B. 693 emulsion each day.

From 17th to 20th February only two tablets of M. & B. 693 were given *b.d.s.* each day.

Altogether four intramuscular injections of M. & B. 693 emulsion along with 40 tablets of M. & B. 693 were given.

The acute brain symptoms delirium and restlessness disappeared on the 15th February and the temperature began to come down by lysis. The cerebro-spinal fluid examined on 16th February did not show any organisms though it contained a few pus cells. The patient made a slow recovery and was given general tonics which brought him to the normal condition in about two months' time.

2. The second case was that of an inmate of the Borstal Institution, a young man of about 20 years of age. On the evening of 5th April last, he had fever 102.8°F., with severe headache and vomiting. Head was retracted and the patient was delirious and semi-conscious. Limbs were rigid and Kernig's sign was present. Lumbar puncture was done at once and the fluid drawn was found to be turbid and came out under a fair pressure. The fluid, examined next morning, showed many Gram-positive diplococci and pus cells along with increase of protein and absence of sugar. A culture did not show any growth, probably on account of late inoculation of the fluid into the media (16 hours after its withdrawal from the spine). The patient was at once given 4 tablets of M. & B. 693 along with intramuscular injection of solution 5 c.cm. of prontosil 5 per cent. After six hours four more tablets of M. & B. 693 were given. The next morning

the temperature of the patient came down to 99°F., and in the evening it went again up to 102°F. The acute cerebral symptoms also subsided though there was a slight rigidity of the body. On 6th and 7th of April, three tablets of M. & B. 693 *t.d.s.* along with one intramuscular injection of prontosil 5 c.cm. were given each day. From 8th to 12th April, only one tablet of M. & B. 693 was given *b.d.s.* by mouth and the treatment was discontinued after that. Altogether 36 tablets of M. & B. 693 and three intramuscular injections of prontosil (5 c.cm. of a 5 per cent solution) were given.

The patient's temperature was normal on the 10th day of the attack and he made an uneventful recovery.

In neither of these cases was an acute focus of pneumococcal infection observed in the lungs, throat, or ears, hence the presumption is that the infection in the meninges was a primary one.

In both these cases the blood count was made after 8 days of treatment with M. & B. 693 and no leucopenia was noticed, which is sometimes observed after its administration.

Acknowledgments

I am much indebted to Colonel G. A. Khan, I.M.S., for the facilities afforded to me and also for his permission to publish these case notes. Also I wish to express my thanks to Major Taylor, I.M.S., and to Dr. Raghbir Singh of the Mayo Hospital who took special interest in the first case, and I am thankful to Dr. Man Mohan Singh and Dr. Nand Lal of the King Edward Medical College Pathological Department, for giving me their assistance in the second case.

ACUTE TONSILLITIS TREATED WITH SOLUSEPTASINE

By J. C. BHATTACHARJEE, L.M.P.
Darjeeling Himalayan Railway Hospital, Siliguri

THE patient was a female aged about 60 years.

History.—She felt pain in the throat the previous day and had had no sleep at night. The condition became aggravated so quickly that by the morning she was unable to swallow and any attempt at swallowing even water was followed by ejaculation through the nostrils. She had a rise of temperature since the start of the pain.

On examination the patient could hardly open her mouth and examination of throat, done with much difficulty, revealed both tonsils inflamed and enlarged to such an extent as to overlap each other causing occlusion of the throat. The right one was bigger than the left, but both were covered by scattered white patches.

The patient was advised hot application externally and was given 10 c.cm. of 10 per cent soluseptasine (May and Baker) intramuscularly.

The next morning, the condition was the same and another 10 c.cm. of soluseptasine was injected. In the evening the temperature came down and the patient was able to take sips of glucose water occasionally.

The patient was much better the next morning, when she was able to open her mouth to some extent. As she could swallow liquid, she was given two tablets of proseptasine (May and Baker) (1.0 gm.) crushed and emulsified in water to be taken three times a day; this was continued two days more and her recovery was uneventful.

Indian Medical Gazette

DECEMBER

THE ÆTIOLOGY OF EPIDEMIC DROPSY

DURING the last two years a distinct advance has been made towards the solution of the ætiology of epidemic dropsy, though the controversy, on this problem, which has enlivened these columns at short intervals throughout the last sixty years, is not yet closed. We can probably look forward to much further discussion before the exact cause of this disease is finally settled, if in a matter of this kind there is such a thing as finality.

The theories that have been put forward can be grouped as follows:—(i) That it is caused by an infecting organism, a bacterium or a virus, that can be passed from person to person; (ii) that it is an intoxication acquired from (a) diseased rice, (b) mustard oil, or (c) some other source; or (iii) that it is a food-deficiency disease. Whilst the infection theory has had advocates from time to time, it has never claimed a large following, and nearly all epidemiological and experimental evidence is directly opposed to this mode of origin. The other theories are all associated with food, with errors of omission or commission in dietary, and it is mainly around this that the hypotheses of the last century have circled.

Rice has nearly always occupied the centre of the picture; it is natural that it should, as the communities affected are all rice-eating communities, but little progress was made with the identification of the noxious factor in rice, and most of the theories put forward were backed by scanty and often equivocal experimental data. Whilst broad epidemiological observations (e.g., that the disease is for all practical considerations confined entirely to rice-eating people), and a number of amateur enquiries supported the rice-toxin theory, no expert epidemiological investigation of a specific outbreak had been carried out, and in our editorial columns in September 1935 we commented:—

‘The epidemiological investigations must be raised from the anecdotal to the scientific level. The population subjected to enquiries must be a large one and only selected on a geographical, not on an economic, social or religious, basis; the enquiries must be made amongst those who have not, as well as those who have, suffered from the disease; the mild cases of the disease must also be taken into account and this presents difficulties as it means that a careful medical examination of the whole population at the time of the outbreak is necessary; histories taken at a later date may be misleading. Very few

investigations of this nature have been undertaken, but it is only through such investigations that we are likely to reach a solution of the problem.’

Such an expert epidemiological investigation was undertaken by Dr. R. B. Lal, the officiating director of the All-India Institute of Hygiene, and other members of the staff of that institution, in six different areas, in Bengal, Bihar, and Assam, including a tea estate, where an outbreak of the disease had been recognized and reported by Dr. Charles Terrell. These investigations appeared to point once more to mustard oil as the probable vehicle of the noxious factor, and the same workers were able to produce suggestive symptoms in volunteers fed on samples of mustard oil that had come under suspicion in epidemic dropsy outbreaks. A search through the literature bearing on the mustard-oil theory brought to light a paper by Sarkar (1926), who recorded the production of symptoms resembling epidemic dropsy in man after the consumption of oil which had been accidentally adulterated with argemone oil. Argemone oil (local name, *sialkata* or *katakar* oil) is the oil expressed from the seeds of a plant *Argemone mexicana* which often grows wild in mustard fields. The seeds of this plant bear a superficial resemblance to the black variety of mustard seed and the oil expressed from them resembles mustard oil. Another paper (Kamath, 1928) described an outbreak in Ganjam district amongst people who do not use mustard oil. In this outbreak oil pressed from certain seeds locally known as *odissimari* was implicated. These seeds were identified later (*I. M. G.*, 74, 193) and found to be the seeds of *Argemone mexicana*.

Little notice was taken of these two papers at the time, but they form good examples of how isolated, and apparently irrelevant, observations are sometimes the key pieces necessary to complete the picture; in the second of these papers the writer's main theme was the support which his observations gave to the infection theory, but Dr. Sarkar was definitely of the opinion that it was the contaminating *katakar* oil which produced a syndrome closely resembling epidemic dropsy; for this reason we are reproducing his paper *in extenso* below.

The presence of argemone oil in mustard oil can be readily demonstrated by a simple colour change following the addition of nitric acid to the suspected oil and it was found that a positive reaction for argemone oil was obtained in the oils implicated in outbreaks of the natural disease. There was sufficient epidemiological data to justify a practical test of the hypothesis advanced by Sarkar in 1926 and this test was made early this year by Colonel Chopra, Major Pasricha and others at the School of Tropical Medicine, who showed by feeding experiments in man that the oil expressed from the seeds of *Argemone mexicana* led to the development of signs and symptoms of epidemic dropsy. Further experimental work in this

institution has shown that this oil is toxic to laboratory animals, but that, when mustard oil containing the adulterant oil is heated till it fumes, it is not so toxic. This is important, particularly in view of the custom prevalent in Bengal of using raw unheated oil in food and for anointing the body.

We have now arrived at the position in which mustard oil has been incriminated once more, but on this occasion the case against it rests on a much sounder basis of epidemiological and experimental evidence; argemone oil, a common adulterant of mustard oil, has been shown to produce symptoms identical with those of epidemic dropsy, whether it is administered accidentally or experimentally; and finally in a number of recent outbreaks it has been found that the mustard oil used by the victims was badly contaminated with argemone oil and that when its use was discontinued the outbreak subsided. Thus, taking the most optimistic view—though in practice things do not always work out quite as satisfactorily as one is led to hope—we may consider the case from the public-health point of view complete; and as there is a simple test for detecting the presence of argemone oil in any sample of mustard oil, it should be possible, by education and if necessary legislation, to prevent the sale and use of argemone-contaminated mustard oil, and to reduce epidemic dropsy from the status of a major public-health problem to that of an interesting pathological curiosity.

So much for the public-health point of view, but from the scientific point of view the position is not so satisfactory; we know that argemone oil contains a toxic agent but we do not know its nature or how it acts, whether it is an independent poison that produces its ill-effects, grain for grain according to the dose in which it is taken, or if the substratum is an important factor, and if its degree of toxicity depends on the excess of one food substance in the diet or on the absence of another. Argemone oil is not an adulterant in the sense that it is often added to the oil by the retailer, deliberately for the sake of increasing his profit, but it is an accidental contaminant of the mustard crop as it grows in the field; it is a self-sown weed which can be distinguished easily from the mustard plant when the crop is harvested, and, though the seeds are very similar, they could be picked out by a careful farmer. It is quite understandable that some years would be more favourable to the weed than others and that its percentage incidence in the crop will vary from place to place, but apparently it is a very common contaminant and a large number of samples of oil show its presence, so that it is easier to account for the wide prevalence of the disease than it is to understand why it is not more prevalent. It is, for example, not quite clear why epidemic dropsy is comparatively rare amongst the poorer Anglo-Indian community

who use mustard oil for cooking almost exclusively. Is it simply because it is heated and partly inactivated, or is it something to do with the general composition of their diet, in which rice does not preponderate to the extent that it does in most Bengalee diets? There has long been a strong belief, prevalent amongst both patients and doctors, that rice *per se* is bad for an epidemic dropsy patient; this belief is independent of the rice-toxin theory, because it applies to any form of rice, sound or diseased, and Professor Ellis C. Wilson, studying cases of epidemic dropsy in the hospital attached to the School of Tropical Medicine, a few years ago, found that there was a distinct increase in the œdema whenever a patient was given a rice diet. There is therefore some evidence that people who live on a diet consisting largely of rice, by virtue of its high carbohydrate or low vitamin content, are more susceptible to the disease, and that rice, though not the main culprit or the vehicle of the noxious factor, does play a part in the ætiology of epidemic dropsy.

In the study of vitamins, the idea of 'conditioned toxicity' is now gaining ground; there are numerous examples reported of the toxic effect of a toxic substance being conditioned by the nature of the diet and/or the state of vitamin saturation of the subject, *e.g.*, selenium poisoning and a high protein diet, lead poisoning and vitamin C, and indol and vitamin B. Is this possibly another such example? Such an hypothesis would provide a means of co-ordinating some of the earlier theories regarding epidemic dropsy with the latest one, for vitamin deficiency was visualized as a possible cause long before the present vitamin age, and even before the word *vitamine* was invented.

There is every indication that medical research has scored another practical triumph, but that the fascinating and stimulating story of the rise and fall of a serious epidemic disease, which has been written *in extenso* in the pages of this journal over a period of sixty years, has now reached its final chapter, we do not believe.

KATAKAR OIL POISONING

By SARASI LALL SARKAR, M.A., L.M.S.

Civil Surgeon, Malda

(Reprinted from *Indian Medical Gazette*, 1926, Vol. LXI, p. 62)

THE following occurrence shows that symptoms like those of epidemic dropsy have resulted in some cases from the use of adulterated mustard oil.

In a village named Attar, situated about three miles from the Bamangola Thana in Malda district, there occurred a few cases resembling epidemic dropsy, which on careful investigation were found due to the use of mustard oil adulterated with what is known as *katakar* oil. The cases occurred about three years ago in August 1922. I intended to publish the reports of the cases, after ascertaining, if possible, something about the physiological action of *katakar* oil. But as I have

not found this last to be possible I content myself with publishing the notes of these interesting cases from my note book on the eve of my transfer from this district.

Katakar oil is the oil obtained from the mustard-like seeds of an Ayurvedic medical herb known as *Stalkata* which has multi-lobed thorny leaves and produces bell shaped bright yellow flowers. The scientific name of the plant, as ascertained from the Curator of the Royal Botanical Gardens, Calcutta, is *Argemone mexicana* Linn. an American weed that has run wild throughout the country, and is commonly known as the Mexican prickly poppy.

The following is a brief account of the occurrence resulting from the use of mustard oil adulterated with *katakar* oil.

Five or six days before the *Janamastami* festival, i.e., on the 9th or 10th August, the wife of Gamaroo, an oilman, prepared some *katakar* oil, as generally used medicinally for such skin diseases as scabies and eczema, in an oil-mill and the oil-mill was put aside without being washed or cleansed properly. Her husband, the oilman, was ignorant of this fact and he prepared some mustard oil in the same oil-mill, and this was taken for cooking purposes just before the *Janamastami* festival in the houses of the following persons:— (1) Ramchandra Mondal, (2) Pancha Mondal, (3) Moti Mondal.

The main ceremony and the chief pleasure of the *Janamastami* festival is frying cakes of the thick juice obtained from palm fruits in mustard oil and eating them. Thus a large quantity of this adulterated oil went into the system of the members of these families on the occasion of this festival and all the members of these three households were affected.

In the house of Ramchandra Mondal, there was a boy aged 5 years and another boy aged 12 years, four adult females and seven adult males ranging from about 17 years to 40 years. All these were affected.

In the house of Pancha Mondal a boy aged 7 years and an adult aged about 42 years who were badly affected died subsequently. Besides this, three boys ranging from 10 to 13 years of age and one adult male of 52 years of age and two adult females were affected in the house.

In the house of Moti Mondal two boys aged 5 years and 7 years, three adult females, and two adult males were affected.

The date of the onset of symptoms was the 12th of August, 1922. The earliest symptoms were excessive spitting and vomiting, which was followed by disturbance of the bowels, followed by gradual oedema of the feet and legs. The affected persons placed themselves under the treatment of a village quack on the 21st of

August, who treated them up to the 31st of August without benefit. Meanwhile the affected families were able to discover the fact that their disease was due to the use of adulterated oil on *Janamastami* day. On hearing about the epidemic I wrote to the Medical Officer, Bamangola, to send me any information which he possessed regarding the cases. He confirmed the fact that the outbreak of the disease which so resembled epidemic dropsy was really due to the use of adulterated oil, but the clinical description was very meagre in his report and is contained only in the following lines:—

'I was called to attend the cases on 5th September, 1922, and found the following symptoms:—

1. Intense pain all over the body.
2. Inflammation of the leg from the toes to the hip.
3. Profuse diarrhoea in some cases, and in others severe constipation.
4. Slight fever running up to 101°F.'

The cases were subsequently seen by the medical officer a month later, when he found these symptoms to be gradually subsiding.

I saw some of the cases, a month later, and found some amount of solid oedema left on the lower part of the leg and feet in some cases.

Two of the girls who went to buy oil from the oilman finding only a very small quantity of residual oil left, smeared the oil over their heads. On the night of the same day the scalp was found to be inflamed with a burning sensation on the head and later on there was marked falling of the hair.

Regarding the properties of the oil derived from the seeds of this plant, the following information is contained in the *Dictionary of Economic Products*, by Sir George Watt, Vol. I, part III, pp. 306-309:—

'The seeds yield a pale yellow, clear, limpid oil; used in lamps and medicinally in ulcers and eruptions.

There is also a great difference of opinion as to the action and dose of the oil of *Argemone mexicana*.'

Postscript.—The following is a report on the analysis of *katakar* oil from the Director, Bengal Public Health Laboratory:—

	Extracted with ether	Expressed by machine
Refractometer reading at 40°C.	60.9	62.0
Saponification value ..	189.8	193.2
Iodine value ..	123.88	125.3

FROM WARFARE TO WELFARE

(BEING AN EXPOSITION OF THE SOCIAL SERVICES OF THE RED CROSS IN COMMEMORATION OF ITS 75TH BIRTHDAY)

By KHAN BAHADUR A. HAMID, D.P.H.

(Organizing Secretary, Indian Red Cross Society, and General Secretary, St. John Ambulance Association, Indian Council)

THE world-wide humanitarian organization of the Red Cross is celebrating its 75th anniversary during 1939. It has been a great boon to the world and it is capable of doing immense good in the field of health and welfare. A history of its development and an account of its activities with particular reference to India may

therefore be of interest to the medical profession.

This international organization was formed 'for the amelioration of the condition of wounded in armies in the field'. It took its origin chiefly through the efforts of Henri Dunant, a Swiss gentleman of humble means, who had been greatly influenced by the work of Florence Nightingale in the Crimean War of 1854-6, and by his own experience at the battle of Solferino during the Franco-Austrian War of 1859. This battle had lasted for fifteen hours and claimed as its victims 38,000 dead or dying soldiers for whom there were little medical or nursing facilities. Delegates of sixteen countries assembled on 23rd August, 1864, and

signed an agreement. This agreement, called the Geneva Convention, is still in force. It recognized the principle of the neutrality of the sick and wounded in war time and authorized the formation of voluntary relief societies to supplement regular army services. It adopted a distinctive symbol—the Red Cross on white background—to be worn by the personnel of these societies, and to mark hospitals and ambulance stations on the battlefield. This symbol honours the country from which this humanitarian movement had originated, as it is the Swiss Flag with reversal of colours. The Red Cross, which did not take its origin on any religious ground, thus became a recognized emblem of mercy.

The signing of the Geneva Convention not only led to the formation of a number of national Red Cross societies but it gave rise to a small committee, called the International Red Cross Committee composed of Swiss citizens.

Indian Red Cross Society Headquarters, New Delhi.

which became the legal guardian of the Convention to see that it was faithfully observed. This Committee also helped to bring the various national societies in touch with one another and to encourage the formation of new societies. The Red Cross started as a voluntary organization for purposes of war, it did admirable work during the Great War, and can well be said to have been the 'greatest mother in the world'.

When the war came to an end the fighting forces were demobilized. Every Red Cross society had expanded to meet the pressing needs of war, and the end of the war found the societies in a stronger position than ever before. The battles of modern life are no longer fought only on fields and it was decided to utilize the organization of the Red Cross as a weapon for combating the ills which afflict mankind in time of peace. This time Henry Davison, chairman

of the war committee of the American Red Cross, the most powerful of all Red Cross societies, seeing in a world federation the possibility of adding immeasurably to the happiness and welfare of mankind, took the initiative for the adoption of a peace-time programme based on health education. The result was that the League of Red Cross Societies was formed in May 1919 for the purpose of the 'improvement of health, the prevention of disease and the mitigation of suffering throughout the world'. Thus, the Red Cross passed on from Warfare to Welfare and the year 1939 is the twentieth anniversary year of this landmark in its development.

The League is a source of inspiration for the Red Cross all over the world and the living example of truly world-wide co-operation, apart from all considerations of race, politics or creed, and is concerned only with the alleviation of human suffering. The Red Cross by virtue of its traditional neutrality and spirit of impartiality is peculiarly fitted to throw a bridge between the people of the world and to foster mutual understanding. The League is pledged to be a non-political, non-governmental and non-sectarian organization. It is a federation of 62 national societies with its headquarters in Paris, and India is a full member of this federation. The International Red Cross is a term which collectively connotes the International Red Cross Committee, Geneva, the League of Red Cross Societies, Paris, and the National Red Cross Societies. It represents the organized co-ordination of these bodies by means of a single supreme body, the International Red Cross Conference, which is held once in four years. The last Conference was held in London in June 1938.

The control of the affairs of the League is vested in a Board of Governors which includes a representative of each national society. The League's budgetary requirements are met by contributions of national societies. The experience of the war and after-war periods has encouraged national societies to rely with increasing confidence upon public support and to seek to extend their membership to all classes of the population. The membership is now about 20 million of adults and another 20 million of children and adolescents.

Red Cross societies have assumed heavy responsibilities in connection with the work undertaken on behalf of war sufferers, namely the training of disabled men, assistance to ex-service men, provision of homes for the permanently disabled and assistance to the populations of devastated regions. In the health field, mention must be made of the important

contribution of societies in connection with permanent hospitals, their participation in campaigns against tuberculosis, venereal diseases, malaria and other epidemics, their co-ordination in connection with hospital social service, dispensaries and clinics, including child clinic and maternity centres, and their work in connection with the formation of emergency hospital and mobile ambulances. They have also assumed responsibilities for the training and enrolment of nurses and for assisting them and other personnel in forming voluntary corps to be mobilized in emergencies.

The aim of the extension of the programme has been to create among all classes of society an enlightened desire to improve health conditions and public knowledge of the means by which they can be obtained, and to promote popular health education, public-health nursing work and Junior Red Cross work.

The Junior Red Cross is described as a particularly appropriate means of furthering the education of the rising generation in the health field and of inculcating in children, at an age when they are most amenable to suggestion, the spirit of service which is at the root of the Red Cross ideal, the motto of the Junior Red Cross being 'I Serve'. Although a late-comer among youth movements, in numerical strength and geographical extent it is the largest youth organization of the world to-day.

During the last war the Red Cross work in India was done by an Indian Branch of the Joint War Committee of the Order of St. John of Jerusalem in England and the British Red Cross Society. It was after the war that the Indian Red Cross Society was constituted under Act XV of 1920, and the administration of the surplus funds of the Joint War Committee consisting mostly of the 'Our Day' collections made on 12th December, 1917, was passed on to the Society. The headquarters of the Indian Red Cross Society is located at 20, Talkatora Road, New Delhi, in its own spacious building which is a gift of His Highness the Nawab of Junagadh. The Society has 26 provincial and state branches and 265 district branches. The adult membership is 20,000 and the junior about 5 laes. Its affairs are controlled by a representative managing body of 25 members. His Excellency the Viceroy is the President of the Society. There are various grades of membership and the constituent branches belonging to the confederation are autonomous in their own sphere of activity. The interest of the invested funds amounting to about rupees three laes is distributed to provincial and state branches in proportion to the contribution made by them to the 'Our Day' fund. The branches supplement these funds with the subscription of members whom they enrol. The important heads under which the activities of the Indian Red Cross Society may be mentioned are maternity and child-welfare work, popular health education, public-health nursing and

health visiting, relief work in disaster, supply of comforts to hospitals and Junior Red Cross work in schools.

In commemoration of the 25th anniversary of the accession to the throne of His Late Majesty, King George V, the Silver Jubilee Fund was raised in India for charitable purposes, and among the institutions which were selected as beneficiaries, both at headquarters and in provinces, were the Indian Red Cross Society and the St. John Ambulance Association. The funds of the Indian Red Cross Society were augmented to the extent of about 8 laes after distributing about 12 laes to various institutions and organizations, e.g., the King George Thanksgiving (Anti-Tuberculosis) Fund and the British Empire Leprosy Relief Association. The Indian Red Cross Society may appear to be a rich body, but the demands on it for assistance are numerous and support can be given with limitation in order to maintain its solvency, and the necessity for self-help on the part of its constituent branches by enrolling more members cannot be too strongly emphasized.

The recovery of His Late Majesty King George V from serious illness in 1929 evoked very warm felicitations throughout the Empire. In India they found expression in the form of a Thanksgiving Fund for anti-tuberculosis work and the administration of a sum of Rs. 9½ laes was vested in the Indian Red Cross Society in 1931. This has only recently been dissociated from the Society and passed on to the new Tuberculosis Association of India for which Her Excellency the Marchioness of Linlithgow had launched an appeal. A full account of the Tuberculosis Association of India is given in the *Indian Medical Gazette* of April 1939.

Maternity and child welfare.—Although the foundation of the Countess of Dufferin Fund in 1885 was the first organized effort to meet the need of a supply of women doctors for the women in India, definite steps for the improvement of the conditions of child-birth by training the hereditary *dai* class were taken in 1903 with the formation of the Victoria Memorial Scholarship Fund.

The next step was the formation of an All-India Lady Chelmsford League in 1920 for the provision of health and maternity supervisors with the main objects of training of health visitors at health schools, propaganda through literature, lantern slides and health exhibitions, and the formation of branches in provinces. The Indian Red Cross Society also carried on its child-welfare activities and in practice there was considerable overlapping. It was therefore considered desirable not only to amalgamate the two organizations and take over the Victoria Memorial Scholarship Fund, but also to include army child-welfare work among the wives of British soldiers and Indian sepoys under a common scheme. Thus came into existence the maternity and child-welfare bureau of the Indian Red Cross Society in

1931. The present annual fund for the activities of the bureau is about 1.25 lacs.

The maternity and child-welfare bureau is the only organization in India which is called upon to give assistance and advice in all branches of child welfare and has to play a special rôle in this respect, as it is through the agency of its local maternity and child-welfare organization that the work is conducted in provinces and districts. The bureau establishes policies, concentrates its attention on training workers, produces propaganda material and collects and supplies information. In 1938 grants-in-aid were given to the health schools for the training of health visitors at Delhi, Calcutta, Madras, Poona and Rangoon. A number of stipends are available for students at these institutions. One school is to be opened in Lucknow shortly. Grants have also been given to the Teachers' Nursery School, Madras, the Kindergarten, Mysore, and the School of Mothercraft, Bareilly. Legislation relating to the registration training and the qualifications for the appointment of health visitors has been passed in several major provinces and they have power to regulate standards. The diploma of the health school, Delhi, has received recognition of the Government of India. The Rangoon health school is not to be accounted for in future as Burma has been separated.

Grants have been given to certain special schemes for maternity and child-welfare work, one of which is towards the work of the Najafgarh health unit, and the U. P. provincial branch supports all the maternity and child-welfare work in the Partabgarh (Oudh) health unit, both of which have been established with the aid of the Rockefeller Foundation. The staff employed by local committees includes trained indigenous *dais*, trained non-indigenous midwives, maternity supervisors, health visitors and medical women. Some branches concentrate on domiciliary midwifery, some on maintenance of small maternity homes, others on welfare centres. The centre which shows the most successful work is awarded the Irwin Challenge Cup.

There are ten or twelve places where schools for midwifery training have been established and over 200 non-indigenous midwives and over 1,000 indigenous ones have been trained annually. Some of the *dais* obtain the Victoria Memorial Scholarship certificate. The army child-welfare work owes much to the help and enthusiasm of voluntary workers. There were 54 Indian and 26 British army centres during 1938.

The Indian Red Cross Society co-operates with the Trained Nurses' Association of India in the work of the Indian National Committee of the Florence Nightingale International Foundation and provides for a scholarship for training a suitable health visitor in the international course for post-graduate nurses in England annually.

A scheme of enrolment of trained nurses for emergency or war service, in co-operation with the Trained Nurses' Association of India, enables the Society to maintain a list of nurses who can be called upon for mobilization at short notice, either in case of war or in a national disaster. Nurses were mobilized to help the injured at the Bihtra railway disaster in 1937. The much-coveted Florence Nightingale medal for meritorious work in nursing in India is awarded biennially to deserving candidates on the recommendation of the Indian Red Cross Society.

Popular health education is the most important aspect of the peace-time work of the Indian Red Cross Society, whether done through the maternity and child-welfare centres, for pre-natal, natal, post-natal, toddler or pre-school stages, through the Junior Red Cross for the school age, or through other agencies for the adult. Its need is as great in urban areas as in rural. A large variety of material is stored in the Red Cross Depôt at headquarters which is distributed to various agencies and the teaching work is done in all its forms.

Pictorial posters, pamphlets, lantern slides and cinema films explaining the conditions of prevailing epidemic diseases in the form of stories of common occurrence, and in local setting, are extensively made use of besides demonstrations at health exhibitions. School hygiene, prevention of blindness, maternity and child welfare, tuberculosis, nutrition, rural hygiene and sanitation are among the other subjects on which different kinds of material have been prepared and utilized.

The work of a fully-equipped cinema section of the Indian Red Cross Society is fourfold, *viz*, film production, its distribution through a circulating library, slide production and still photography. The library has 35 films of standard and about the same number of sub-standard sizes and there were 425 demands on the film library in 1938. General press publicity and publicity through radio talks are also done. The Indian Red Cross Society issues an illustrated bi-monthly *Journal* and another, the *Indian Junior*, which are entirely supported by their subscriptions. Some provincial branches also publish their own journals.

The Junior Red Cross is organized through school groups with the help of the teacher who is designated by the internationally recognized appellation of Counsellor. The following are its principal aims:—

- (i) Promotion of health, especially the practice of health habits.
- (ii) Service to the sick and suffering.
- (iii) International friendliness promoted through the exchange of school correspondence albums between Junior Red Cross members.

The Junior Red Cross grew out of a sense of the necessity for improvement in personal

hygiene and the recognition that the formal teaching of hygiene could do very little to form habits of healthy living which are so essential. It has a purely co-operative character in that it does not seek to form independent groups with outside rules but to bring into life school influences that can be used by Counsellors. The Junior Red Cross performs the stimulative function of the voluntary organization which touches life at many points and provides the young members with a means of self-expression and self-realization in relation to the community, growing with their growth and preparing them, when their junior days are over, to be more serviceable to their country and perhaps to the world. Physical training ceases at doing exercises and has no educational side about it, and it must have physical education grafted on it. The latter is an educational programme in normal habits and functions and actions of the body with an appreciation of healthy living in respect of thought, action and every other aspect, and here comes in the utility of the Junior Red Cross.

The Junior Red Cross with its activities for the promotion of health, spreading in all directions, and especially in anti-epidemic and village improvement work has fully established itself in India. The practice of health habits, cleansing of school premises, gardening, soap making, canteen management, sale of stationery on a co-operative basis, first aid, health exhibitions, poster and model making, writing of health essays, health propaganda, health plays, competitions, rural work and exchange of international correspondence albums have kept the spirit of the Red Cross alive among the 5 lacs of members of the rising generation. Provincial branches award certificates of recognition to Counsellors of the two or three years' good service and headquarters gives a badge after five years. Lectures on prevention of blindness and on nutrition are organized for teachers in training institutions.

Junior members have been most active in learning first aid and home nursing, and in forming cadet divisions, which correspond to adult ambulance and nursing divisions of the St. John Ambulance Brigade overseas, and both have rendered useful public service and service to the sick and suffering. The part played by the Knights of St. John in works of charity about one thousand years ago is now a matter of history. In 1877 the Order of St. John with its motto to 'work for the good of mankind' established the St. John Ambulance Association as part of the voluntary-aid movement to train men and women in first aid, home nursing and ambulance work in order to furnish aid to the sick and wounded, and to co-ordinate in days of peace and war all offers of voluntary assistance. The trained personnel formed a number of detached ambulance corps for combining their individual efforts for the public advantage and they were banded together in a Brigade in 1887,

and the first corps overseas was formed in 1892. The ambulance work among railwaymen, police and volunteers started in India in 1901. The Indian branch, afterwards Indian Council of the Order, was formed in 1904 and the first brigade ambulance division (men) and nursing division (women) were formed in 1905. The St. John Ambulance Brigade overseas was established in 1911.

The Indian Red Cross Society has recognized the St. John Ambulance Association and Brigade as the ambulance division of the Society and all ambulance responsibilities of the Society have been delegated to them, including emergency relief organization in so far as it concerns personnel. The Society has therefore agreed to give financial support to the Association. There are separate membership subscriptions for the Association. Both the organization at headquarters and in provinces are more or less under a joint management. The St. John Ambulance Association (Indian Council) has a fixed income of about Rs. 30,000. It maintains a stores depôt for the supply of books and equipment. It issues certificates for courses in first aid, home nursing, domestic hygiene and mothercraft, hygiene and sanitation, Mackenzie school course, and air raid precautions and anti-gas measures. There are about 300 centres of the Association in provinces, states, districts, and on railways, and in 1938 alone the Association issued over 21,000 certificates to members of military forces, railway and police employees, men of the criminal tribes, inmates of prisons and reformatory schools, workers in mines and factories and students in educational institutions, besides about 8,000 for the elementary, Mackenzie school, course.

For brigade work of the Ambulance Department there are 13 districts, which have been or are being formed on a provincial basis and are in charge of the heads of the respective medical departments. There are 112 ambulance divisions of uniformed men, 35 nursing divisions of women, besides 37 divisions of cadet divisions of youths, and more are in formation. A scheme of voluntary aid reserve, formerly voluntary aid detachment, consisting of members of nursing divisions has been introduced with the sanction of the defence department to supplement the military nursing services in India in time of war or national emergency.

The history of the Society is replete with disaster-relief operations made in cash, kind and personnel. The Bihar earthquake of 1934, the Quetta earthquake of 1935, the Bihta Railway disaster of 1937 are among the instances where valuable services were rendered. Active part in relief work has also been taken at fairs, exhibitions and other public functions, and in floods, fire and famine. Among other instances of relief measures may be mentioned assistance to the sufferers of a severe malaria epidemic in Ceylon in 1934-35, and to refugees in Abyssinia, Spain, France and China.

many other workers have played their parts. In connection with the important International Conference

on Rabies held in Paris in 1927 it was stated 'Indian experience dominated the Conference'.

The Treatment of the Enteric Fevers

By HAROLD COOKSON, M.D., M.R.C.P.

(From the *Practitioner*, Vol. CXLII, June 1939, p. 683)

THE enteric infections comprise typhoid and paratyphoid fevers. The former is due to infection with *Bact. typhosum* and the latter to infection with *Bact. paratyphosum* A, B or C; in this country paratyphoid infections are most commonly with *Bact. paratyphosum* B, less frequently with A and only very rarely with C. Typhoid fever proper is the most severe of these infections and the prevalence of epidemics has been greater in the last few years. The mortality in many other acute infections has been considerably reduced by the introduction of new methods of treatment, but that of typhoid fever is still about 10 per cent or more, and its fatality rate is higher than that of most other acute infections commonly occurring in this country. The treatment of the enteric infections can be conveniently considered from four aspects:—(1) prophylactic, (2) general, (3) symptomatic and (4) specific.

PROPHYLACTIC

The patient must be strictly isolated and domiciliary treatment should not be lightly undertaken. If satisfactory accommodation and the services of nurses specially trained in the care of infectious cases are not available in the home, removal to hospital is to be strongly advised. While handling the patient the attendants must wear gowns and wash thoroughly in soap and water afterwards. His bed and personal linen must be soaked in 1 in 20 solution of carbolic acid before being boiled, and crockery, enema syringe, bedpan, urinal, thermometer, stethoscope and any instrument used on the patient must be efficiently disinfected. Stools and urine may be regarded as more or less pure cultures of the infecting organisms and must be treated with the greatest care. The urine should be mixed with an equal volume and the stools with twice their bulk of 1 in 20 carbolic solution and allowed to stand for several hours before being poured down the drain. If the patient should take a bath the water is afterwards treated with chloride of lime ($\frac{1}{2}$ lb. to 50 gallons of water) and allowed to stand for half an hour before being discharged, and sponging and washing water should be dealt with on similar lines. Sputum, vomit, discharge from the ears or abscesses, or any other wound which may be present, require disinfection. All these precautions are continued until bacteriological examination of the stools and urine is negative on three consecutive occasions, the specimens being collected at intervals of not less than three or four days.

If bacilluria or positive stool cultures persist for a long time during convalescence, the individual is regarded as a possible chronic carrier. The Vi agglutination test recently suggested as an aid to the detection of true chronic typhoid carriers may prove to be of practical value. Urinary carriers may respond to treatment by urinary antiseptics, such as hexamine, mandelic acid, sulphonamide or one of its derivatives. Whether or not hexamine and sulphonamide are also effective against biliary carriers has not yet been established.

GENERAL TREATMENT

In any acute infection the emphasis on general treatment in which skilled nursing plays a large part, varies inversely with the value of the specific treatment available, and the potency of the latter in enteric infections is not yet so high as to displace the general

treatment from its important position. The patient is nursed in a well-ventilated, barely furnished room, kept at about 60°F., and on a narrow bed with a hair mattress and one pillow. So long as the temperature is raised, one sheet and one blanket are adequate covering. Smooth sheets not only add to comfort but lessen the risk of injury to the skin, which should be rubbed frequently with spirit over the pressure points. The buttocks should be washed and powdered after each bowel action. To prevent cracked lips, vaseline, liquid paraffin, or camphor ice may be applied, and the mouth should be cleaned after each feed. The patient is not allowed out of bed until the temperature has been normal for one to two weeks, depending on the severity of the attack.

The high and prolonged fever makes it necessary to supply large amounts of fluid and to try to maintain nutrition by a diet of adequate calorie value. An increase in temperature of 1°F. raises the basal metabolic rate by about 7 per cent; in most cases of typhoid fever with temperature of 102–104°F. the metabolism will be increased by about 30 per cent. With the all-fluid diet as formerly used under-nutrition was inevitable, and it is now believed that a more liberal diet can often be taken with advantage and without increasing the liability to intestinal hæmorrhage. After hæmorrhage from peptic ulcer, for example, there are observations which suggest that immediate feeding with milk in small quantities or even light solids has no harmful effect. The diet to be aimed at for the average adult patient with enteric fever is one containing 3,000 to 4,000 calories (or 30 cal. per lb. body-weight) and the fluid intake should amount to four to eight pints daily, though it is not always possible to attain these levels. It is also necessary to see that the diet is balanced not only in regard to protein, fat and carbohydrate, but also in its content of the accessory food factors. Milk or milk substitutes may still form a considerable part of the diet, but in addition the following can usually be given: cream, lactose, butter, egg, toast, biscuits, mashed potato, custard, junket, rice pudding, blanchmange, cream soup, gruel, apple sauce, milk chocolate, and ice-cream. After a preliminary period of twenty-four hours of two-hourly milk feeds, flavoured with tea, coffee or cocoa, the above-mentioned additions may be gradually made until an intake of 3,000 or more calories is reached. The table at the end shows the general lines of such a diet, though adaptation to the individual patient's tastes and condition will be necessary. Between feeds plain water and barley water can be given *ad lib.*, also lemonade, orangeade, or other fruit drinks with added lactose or glucose. Extra vitamins are called for, particularly C, and although the latter will be supplied in fresh fruit-juice drinks, the pure vitamin in solid form should also be given as ascorbic acid 100 mgm. daily in a milk feed. Vitamins A, B and D are conveniently given as some potent fluid preparation. Alcoholic drinks of any kind are contra-indicated unless the patient has been used to considerable quantities. In stuporose patients adequate feeding by mouth may be impossible and feeding by a tube passed through the nose into the stomach may be attempted. No addition to the diet as outlined is made until the temperature has been normal for a few days, when it is gradually increased. If any symptoms of relapse appear, the diet is at once reduced to the former level.

Hydrotherapy.—In patients with high temperatures, the former rigorous treatment by cold baths and ice packs has now been superseded by more moderate measures, and the tepid sponge is the most satisfactory. If the temperature is accompanied by toxæmia, the

limbs, chest, abdomen and back are sponged and dried one by one, using water at about 90°F., and repeating the procedure four-hourly if necessary. The tepid sponge is contra-indicated if there has been intestinal hæmorrhage or if severe meteorism is present, and if phlebitis has occurred the affected limb is not disturbed. Tepid sponging is not contra-indicated by pneumonia.

SYMPTOMATIC TREATMENT

Symptoms referable to almost every organ in the body may occur in the enteric fevers, and it will be possible to mention the treatment of only the more common ones. For *constipation*, which is more frequent than diarrhoea, simple enemata are indicated, the purgatives of any kind must be forbidden. *Diarrhoea* if excessive calls for extensive reduction in the diet; diluted citrated milk may be given and a starch and opium enema, or a gentle colonic wash-out with water. *Meteorism*, resulting from fermentation and poor intestinal tone, is controlled by reducing the carbohydrate intake; counter-irritation to the abdominal wall in the form of turpentine stupes may be applied, but drugs which stimulate motor activity in the intestine, such as pituitrin or eserine, are best avoided, and the so-called intestinal antiseptics are of no value. *Oral sepsis* must be guarded against by frequent cleaning between feeds, stimulation of salivation with diluted lemon-juice, and by keeping the lips soft with some oily preparation. When intestinal hæmorrhage occurs food and fluid are withheld for twenty-four hours, and an injection of morphine is given if the patient is restless. The various proprietary hæmoplastic sera are of questionable value. After hæmorrhage large doses of vitamin C should be given, either orally or intravenously, 500 mg. daily by either route, since deficiency of this substance is believed to increase the fragility of the capillaries and to delay the healing of wounds. Severe degrees of vitamin-C deficiency were found by Portnoy and Wilkinson in association with hæmorrhage from peptic ulcer. Intestinal perforation demands immediate surgical intervention. The pain of pleurisy, which is not uncommon, and that of non-suppurative cholecystitis, which is rare, may be relieved by local hot applications. If pneumonia develops, and the hypostatic form is the most frequent, the patient should be propped up and, in the presence of purulent expectoration, a drug of the sulphonamide series may be of some value. A drug of this group should also be considered if local septic complications arise, such as otitis, arthritis and superficial and inflammatory foci, but surgical drainage will be called for if a definite abscess forms. For *thrombophlebitis* the limb is raised, bandaged over wool and immobilized. Hexamine has usually been given for *bacilluria*, but the condition may be symptomless and the drug may do more harm than good by irritating the urinary tract with the production of hæmaturia. *Retention of urine*, if not relieved by hot fomentations over the bladder and an enema, is treated by catheterization. *Headache* and *insomnia* may respond to hydrotherapy, but if not, small doses of bromide and one of the barbiturates may be given. In protracted severe cases with delirium an adequate intake of fluid by mouth is generally impossible and it is in such cases that the signs of peripheral circulatory failure, especially a rapid and feeble pulse, are likely to appear. For this condition intravenous infusions of glucose saline, by the drip method if possible, are of great value. Drugs cannot be expected to influence this condition to any great extent, but subcutaneous injection of ephedrine ($\frac{3}{4}$ grain) combined with adrenaline (5 minims) or one of the several proprietary substances chemically allied to ephedrine may be more effective in raising blood pressure than those reputed to act by stimulation of the medulla, such as strychnine and coramine. Digitalis is contra-indicated unless there is coincidental heart disease with congestive failure. Injections of suprarenal cortical extract may be used for the asthenia and low blood-pressure of the later stages of the illness, and good results have been claimed from the routine use of this extract combined with large doses of vitamin C.

Blood transfusion.—Transfusion of blood has a place in treatment under certain conditions. For severe or repeated intestinal hæmorrhage which produces symptoms of shock immediate transfusion is advisable with stored blood of group O. Prolonged cases with severe toxæmia and some anemia due to repeated small hæmorrhages or to the chronic toxæmia may benefit from blood, preferably from a donor who has been actively immunized by T.A.B. vaccine rather than from a subject convalescent from the disease, and in epidemics it is usually easy to find a suitable donor. A further injection of vaccine into the donor twenty-four hours before withdrawing the blood is recommended by Bower but usually such delay is inadvisable. If an immunized subject is not available, antityphoid serum should be given along with blood from an ordinary donor. Against transfusion it might be objected that it would increase the tendency to venous thrombosis, to which embolism may be a sequel. In practice this complication is not found to be more frequent in the transfused cases, nor does the increase in the volume of circulating blood aggravate bleeding from the intestine; on the contrary it appears to have a hæmostatic effect. The blood is citrated and given in amounts of 100–300 cubic centimetres (3–10 oz.) or in larger quantities if the drip method is employed.

SPECIFIC TREATMENT

An ordinary vaccine of *Bact. typhosum* has sometimes been used during the course of an enteric infection, but a good case for its value has not been made out. The use of vaccine is liable to be followed by a severe reaction and, if the symptoms are already serious, this may be dangerous. Vaccines modified by bacteriophage or by incubation with typhoid convalescent blood, by which methods the organisms are lysed, are held to be superior to the ordinary vaccine, but they appear nevertheless to have similar disadvantages. It is doubtful if these methods produce effects other than those resulting from non-specific protein shock.

Antityphoid serum.—Antisera have been used in many countries for at least thirty years, but until recently these have had little success, a fact which is explained by lack of knowledge of typhoid antigens and antibodies. Without this knowledge the preparation and standardization of a potent serum are not possible. To-day, however, as a result of the intensive investigation of typhoid antigens by Felix and his co-workers, it is known that a virulent strain of the organism produces the two antigens termed Vi and O, and that to be effective an antiserum must contain the two appropriate antibodies. The serum now prepared by the Lister Institute (supplied by Messrs. Allen and Hanburys) contains these antibodies in high concentration as shown by the agglutination titres of 1:3,000 or more for Vi antibody (against strain Watson) and 1:20,000 or more for the O antibody (against strain 901). The serum will protect mice against otherwise lethal injections of live *Bact. typhosum* and also against the effects of massive doses of dead organisms, and the several reports so far published on its clinical effects have all been favourable. One of these reports deals with a trial in seventy-three patients in 1936, and a beneficial effect on both toxæmia and temperature was noted in a significantly high proportion of cases. Since that time the potency of the serum has been increased considerably, the titre of the O antibody being doubled and that of the Vi antibody more than trebled.

The serum should be given as early as possible in the course of the disease, either intramuscularly or intravenously, diluted with normal saline if the latter route is used. For an adult three or more doses of 33 cubic centimetres each should be injected at intervals of twenty-four hours. For children smaller doses suffice. The beneficial effect of the serum is usually manifest not later than a day or two after the third injection. If at that time there is still no improvement and the condition of the patient is causing anxiety, it is advisable to give further doses of the serum.

If the patient is known to be allergic or to have received some form of serum previously, desensitization should be carried out by repeated small doses of the serum (0.01, 0.1, 0.2, 0.5 cubic centimetre) subcutaneously at half-hour intervals, and followed by a similar series of injections intravenously. In severe cases the intravenous route is preferable and serum may be conveniently given in a glucose saline infusion. When in spite of precautions the injection is followed by symptoms of anaphylactic shock, adrenaline 5 minims subcutaneously should be given. In practice anything more severe than a rash as an untoward reaction to the serum is rare. For good results early use of the serum in full doses is advisable; in late cases with severe toxic changes in the viscera and nervous system, this method can only be relatively of small value, though serum is useful at the onset of a relapse. The serum is of no value in the treatment of paratyphoid fever.

Specific prophylactic treatment with vaccine of typhoid contacts is a matter which is still controversial, but such persons may be safely given protection by injection of the antiserum. The protection thus conferred will, however, last only for a short period (about two weeks). The dose is 33 cubic centimetres intramuscularly for an adult and 7-20 cubic centimetres for children according to age.

Chemotherapy.—The success attained by sulphonamide and its derivatives in the treatment of acute infections with *B. coli* of the genito-urinary tract and of the portal vein in man, and of *B. coli* septicæmia in animal experimental infections, suggests that these drugs might also be effective in infections of the enteric group, as the organisms concerned are morphologically similar. In mice a single dose of sulphonamide was found to give protection against *Bact. typhosum* and also against *Bact. paratyphosum* B, but its precise value in the treatment of human infections, if any, will depend on the results of extensive observation, which are not yet available. Theoretical considerations would suggest that early treatment with this type of drug combined with antiserum might be the most effective method. On the carrier state preliminary reports give promise that the action of sulphonamide and its derivatives may be of importance. In a case reported by Barer typhoid bacilluria cleared up following the administration of sulphonamide, though previous treatment with hexamine and with ammonium mandelate had failed to sterilize the urine. This patient, however, was recovering from an attack of typhoid fever, and was not a true chronic carrier. Of greater significance is Bazin's report of a chronic faecal carrier of *Bact. paratyphosum* B, in whom the liver bile still gave positive cultures after cholecystectomy, but in whom sulphonamide caused the disappearance of the organism from faeces and bile after hexamine had failed.

Diet in enteric fevers

(3,000 calories)

6 a.m.	Milk, 5 oz.; cream, 1 oz.; lactose, $\frac{1}{2}$ oz.
8 a.m.	Gruel, 7 oz. (e.g., milk, 2 oz.; farex, 1 oz.; butter, 1 teaspoonful; barley water, 5 oz.; sugar or salt to taste); toast, 1 slice; butter, $\frac{1}{2}$ oz.
10 a.m.	Cocoa, 8 oz.
12 noon.	Vegetable cream soup with salt, 8 oz.; egg, 1; toast, 1 slice; butter, $\frac{1}{2}$ oz.; chocolate blancmange, 6 oz.
2 p.m.	Malted milk, 8 oz.
4 p.m.	Milk, 5 oz.; cream, 2 oz.; lactose, $\frac{1}{2}$ oz.
6 p.m.	Milk toast (milk, 4 oz.; cream, 2 oz.; toast, 1 slice; butter, 1; salt); toast or bread, 1 slice; b; ; egg, 1; cup custard, 4 oz.
8 p.m.	Egg-nog, 1 glass.
10 p.m.	Milk, 5 oz.; cream, 1 oz.

Distribution of Fluorosis in India and in England

By D. C. WILSON

(Abstracted from *Nature*, Vol. CXLIV, 22nd July, 1939, p. 155)

ENDEMIC fluorosis has been described in many different parts of the world. Dental fluorosis is found with waters having a fluorine content of one part per million, and in the United States considerable thought has been given to the elimination of 'mottled enamel' by improving water supplies. Stiff backs and other signs of toxic fluorosis are found when the halogen exceeds three parts per million, and in North Africa, where the amount of fluorine in the soil is considerable, attention has been directed to the agricultural and veterinary, as well as to the human aspects of the problem. Industrial fluorosis among aluminium workers who handle cryolite has been described in Denmark. In Arizona, Smith and others found that fluorine plus diet deficiency was a more potent cause of mottled enamel than fluorine alone.

India. Endemic fluorosis has been recognized among men and animals in the Madras Presidency, and fluorine has been found in the well water. In the adjacent areas of the Nizam's dominions, I, with the assistance of Dr. B. K. Badami, director of Veterinary Services, Hyderabad, found dental fluorosis among children in the Mabubnagar district. The cattle, moreover, in this area develop bone lesions with exostoses, which clinically resemble those found among animals suffering from toxic fluorosis, incurred whilst grazing near aluminium factories in Denmark.

During the past few years I have examined more than 9,000 children in various parts of the Punjab, and in certain clearly defined areas I have found evidence of dental fluorosis in the milk and permanent teeth. These areas include the eastern parts of the Mianwali district, villages near Sargodha, Hundewali near Chiniot, villages around Sangla Hill, in and around Kasur, villages near Ferozepore, and certain villages between Bliwani and Hissar. I found that the teeth were most 'mottled' among children from the lowest social classes, who showed also irregularity in the size of the individual teeth. Stiff backs and elbows have been observed among village children who used deep well water in the neighbourhood of Kasur. The Irrigation Research Institute, Lahore, at my request, kindly had water from a number of wells in the Kasur area analysed, and obtained from nil to four parts fluorine per million.

All the places where dental fluorosis has been detected in the Punjab are situated on the Indo-Gangetic alluvium, which is of practically the same composition all over the Province, and there is no reason to suppose that this alluvium contains any fluorine. Geodetic research, however, has shown the existence of a ridge of rock causing shallowing of the alluvium. The places from which I have collected records of clinical fluorosis may fairly be said to lie over this buried ridge. Dr. Heron considers it is reasonable to think the rocks forming the ridge may

that the 'knotts' clay in the Marston Valley has a fluorine content of more than 450 parts per million. We do not know the source of the fluorine in the other parts of England where human fluorosis is found. The brownish-yellow flecks and spots of pigment, together with the dull white opaque areas of dental fluorosis are easily recognized, and if borne in mind, may be noted possibly in other areas.

Life-story of Simple Herpes

(From the *Lancet*, 18th March, 1939, p. 647)

It has long been recognized that clinically herpes falls into two main groups, idiopathic and symptomatic. Before the causal agent was shown to be a filtrable virus present in the fluid of the vesicles it was thought that, in the symptomatic cases, the herpetic eruption was the work of the organism responsible for the primary condition—e.g., the pneumococcus in pneumonia. This hypothesis, however, failed to explain the idiopathic cases. The demonstration of the virus reversed the situation: the idiopathic group now became understandable on the basis of infection from without, even though this was not always easy to establish; but in the symptomatic group no such interpretation was possible, for in the vast majority a recent extrinsic infection could be ruled out. Two possible explanations were accordingly put forward: first, that sufferers from symptomatic herpes are carriers of herpes virus, which is activated by conditions such as pneumonia, malaria, and protein shock; second, that the primary disease gives rise to changes that result in the evolution of herpes virus *de novo*. The latter hypothesis, unpalatable to most virus workers, had its exponents, but the former more reasonable explanation was not long in finding support. In 1922 Levaditi, Harvier and Nicolau demonstrated herpes virus in the saliva of healthy persons, and two years later Busacca isolated it from the conjunctival sac. This proved the existence of carriers of herpes virus and it was soon shown that, judging by samples, about two-thirds of the population have herpetic antibody in their serum. By the investigations of Andrewes and Carmichael and of Brain a close correlation between recurrent herpes and the possession of herpetic antibody was established.

Dr. Burnet and Miss Lush have taken the epidemiology of herpes a stage further. Making use of the egg-membrane technique, which Burnet's researches have done much to make available for virus study, these Australian workers have been estimating herpetic antibody in human sera. They were induced to undertake this investigation by Weyer's claim that herpetic antibody is absent from the serum in early poliomyelitis, and although they were unable to confirm this, they have made a number of interesting observations in other directions. Not only have they confirmed the findings of previous workers as to the widespread existence of herpetic antibody in human sera, but like Andrewes and Carmichael, they have been struck by the fact that the people examined have either much of the antibody or none at all; there is no intermediate group. This finding, as they point out, can only be explained on the assumption that those who are infected with herpes virus become permanent carriers. A further important observation concerns the distribution of herpetic antibody among adults in the different strata of society: they report that the proportion proved much higher in the 'hospital class' than among the well-to-do. It is the persons possessing antibody who carry the virus and are subject to recurrent attacks of herpes, and the uneven social distribution is consistent with the idea that the primary infection takes place in the early years of life; if it is avoided at that time increasing age brings increasing resistance—not, it seems, through the development of a specific immunity but through some change in the mucous membranes that renders them insusceptible to the implantation of herpes virus. There is indeed some positive evidence that the primary herpetic infection does occur early in life. Dodd, Johnston and

Budding have shown that aphthous stomatitis in infants and young children is caused by the herpes virus and they regard this condition as a primary herpetic infection. Burnet and Lush isolated herpes virus from two young children with aphthous stomatitis at a time when neither child had any herpetic antibody in the serum, and three weeks later the serum of one child contained a considerable amount of antibody. To sum up the discoveries of the last ten years one may say that primary herpetic infection, commonly in the form of a stomatitis, occurs in early childhood, and the person thus infected becomes a permanent carrier. If a child escapes infection during the first decade the chance of herpes virus being implanted later becomes remote, the carrier state is not set up, and symptomatic herpes will never develop. In carriers the attack of herpes is attributable to an upset of the balance between host and virus—for example, by infection, worry, fatigue, or menstruation.

One important question remains unsettled: where does the virus reside in the carrier? There are two possibilities. Either it persists in the cells of the affected mucous membrane, or like the virus of zoster it takes up permanent quarters in the appropriate sensory ganglia. Burnet and Lush favour the second hypothesis but have failed to obtain any corroborative evidence, for they were unable to isolate herpes virus from the gasserian ganglia of individuals who possessed herpetic antibody and were therefore carriers. Although this limited failure does not exclude the possibility that herpes virus is carried in nerve tissue, other considerations make it unlikely. In zoster multiplication of the virus in the posterior spinal root ganglion is almost always attended with intense pain, whereas there is no such pain before a herpetic eruption except in those rare cases where herpes simplex simulates herpes zoster. Furthermore, the virus of herpes simplex has been recovered from the mouth between herpetic attacks, and if its residence during quiescent periods is the gasserian ganglion what was it doing in the mouth? One would expect it to lie quiescent in the ganglia until reawakened into activity by some new upsetting factor. In view of these two objections it is difficult to share Burnet and Lush's preference for the second hypothesis; the facts seem to be more readily explained by assuming that the virus persists in the cells of the mucous membrane.

Rickets and Dental Caries

By D. C. WILSON

(From the Proceedings of the Physiological Society, 13th May, 1939. *Journal of Physiology*, Vol. XCVI, 14th June, 1939, p. 8P)

EXPERIMENTAL work has shown that the incidence of dental hypoplasia and of caries is reduced or even abolished by adequate amounts of vitamin D in the diet. Indeed, the association of rickets and 'bad teeth' has been recognized in this country since Glisson's original description of the disease. One would therefore expect that in a community where rickets was widespread the teeth would be much worse than in a similar community in which there was no clinical rickets. This is not necessarily the case, as the following observations show.

During the past three years comparative diet surveys have been carried out among various Indian communities, and over 9,000 children (5-15 years) have been examined clinically by the same observer. The examination included a search for past and present signs of rickets and an inspection of the teeth. The number of teeth present in the mouth was recorded and the number which were carious to naked-eye examination. It was exceptional to find children who had had dental care, but in such cases teeth treated by a dentist were counted as carious. The incidence of hypoplasia and hypocalcaemia sufficient to give a sensation of roughness with a probe was also noted.

Rickets and osteomalacia are exceedingly common in certain parts of north India, notably in the Kangra valley which lies in the Himalayan foot-hills. In an

examination which was carried out there it was found that twenty-four out of a total of forty-five children showed signs of rickets, late rickets or osteomalacia. The same children had almost perfect teeth, with a very low incidence of caries and little hypoplasia. The teeth of these children were, in fact, no worse than those of 938 children in the Central Provinces living on a similar diet and among whom no case of rickets was discovered. These dental findings were communicated to Dr. Marshall Day, who, at my suggestion, examined fifty children in the Kangra valley, all of whom had severe rickets, but nearly all of whom he found to have excellent teeth.

Changes in the Nails as an Aid to Diagnosis and Prognosis

By R. CRANSTON LOW, M.D., F.R.C.P.E., F.R.S.E.

(From *The Practitioner*, Vol. CXLII, May 1939, p. 627)

Few medical men, when examining a patient, make even a cursory inspection of the nails. Yet a good deal of information can sometimes be obtained from these structures. Like every other organ their normal growth depends upon the general health and they are quick to show changes when that is interfered with. When all the nails of the hands and feet show the same alteration the presumption is that it is due either to a congenital anomaly or, in the absence of any adjacent skin inflammation, to some general condition affecting all the nails through the circulation. When only some of the nails are affected and others are quite normal, a local cause should be looked for, such as a recent or remote injury, an infection of the nail itself (as in ringworm) or an inflammation or growth affecting the skin or deeper tissues round the nail. Admittedly changes in the nails are not always of first class importance in drawing attention to the presence of some systemic disease, because in many very different conditions the same nail changes may be found; but these changes may be very helpful in giving support to a diagnosis which is otherwise doubtful. The fact that the nails are affected in any general condition also indicates, to some extent, its severity and so may influence the prognosis.

COLOUR OF THE NAILS

One of the first things to be noted is the colour of the nails. This, of course, varies according as the limb is warm, cold, or cyanosed. Pressure on the nail drives out the blood from the nail-bed and when the pressure is removed the rapidity or otherwise with which the blood returns is a rough index of the vigour or otherwise of the circulation. The commonest alteration in colour is found in *leuconychia*. Everyone is quite familiar with the white spots which appear from time to time in the nails. They may be punctate or arranged in transverse striae, but there are also rare cases in which the nails are completely white and look as if they had been painted with white paint. I have seen this condition in persons who were apparently perfectly normal otherwise. Some of the cases have a family history of the condition, but it has been known to develop when there are trophic nerve disturbances such as occur in nerve leprosy. The small punctate and striate lesions are comparatively common and are generally supposed to be due to trauma. In the striate form the white areas run transversely across the nails, which may show more than one of these lines. They are much more frequent in women than in men, probably due to the fact that when women are manicuring their nails they injure the growing nail-matrix when pushing back the nail cuticle. Althausen and Gunther have drawn attention to the importance of the presence of white transverse bands in all the nails of the fingers and toes as a sign of acute or chronic *arsenical poisoning*. In such cases it has considerable diagnostic value. It must also be remembered that in chronic *arsenical poisoning* there is a concentration of arsenic in the hair and nails. By analysis of pieces of the nails and hairs the suspicion

of such poisoning can be confirmed. Similar white bands on the nails have also been produced by the administration of thallium acetate in order to cause a fall of hair in ringworm of the scalp.

The white colour is usually attributed to the presence of air spaces in the nail due to an injury which separates the layers of the nail substance, but Singer has recently suggested that they are due to imperfect keratinization at the growing nail-matrix owing to a lowered basal metabolic rate, so that keratohyalin granules persist in the cells of the fully developed nail. The light is reflected from these granules and so the white appearance is produced. Singer holds that when the nails are prepared for microscopic examination these keratohyalin granules are dissolved out by the acid used to soften the nail in order that sections may be cut, and so the appearance of air spaces is produced. Once formed the white spots are permanent till they disappear at the tip of the growing nail.

Less frequently than the white marks the nails may show discolorations varying from light yellowish-brown to blue, purple and black. In chronic *arsenical poisoning*, instead of *leuconychia* the nails may show the same brown pigmentation as the skin of the fingers or toes. In Addison's disease, even although the skin is deeply pigmented, it is only occasionally that the nails are pigmented. In most cases the nails look relatively white compared with the brown skin of the fingers and this is specially so when *anæmia* is marked. In the dark-skinned races also this relative pallor of the nails compared with the skin is quite marked. A single longitudinal brown band running down one nail in white persons is usually due to a pigmented *nævus* in the nail-matrix and less definite longitudinal lines and bands are fairly common in the nails of the coloured races.

The slate-blue discoloration of the skin in *argyria*, usually most marked on the exposed parts, is very disfiguring. It is due to the deposit of metallic silver in the epidermis and true skin. The same discoloration occurs in the nail-beds and, as it may be the earliest manifestation of *argyria*, it should always be looked for. If found, the administration of silver, whether externally or internally, should be stopped at once before the skin has become permanently discoloured.

In cases of *chronic mercurial poisoning* a brownish-black discoloration, much darker than in *argyria*, may occur. It is due to the formation of sulphide of mercury in the tissues. A blue-black discoloration of the nails due to *hæmorrhage* under them is very common. It is most often due to an injury, but in bleeding diseases, such as purpura, *hæmophilia* and scurvy, spontaneous *hæmorrhages* may occur under the nails, and in these cases they usually occur under several of the nails. In *tuberculosis dorsalis* also *hæmorrhages* may appear suddenly in all the nails of the toes in association with lightning pains. *Hæmorrhages* under the nails, preceded by neuralgic pains, may also occur in diabetes.

If the *hæmorrhage* in these cases is extensive the pressure of the blood enclosed under the nails may cause considerable pain which can be relieved by drilling holes in the nails. In severe injuries with *hæmorrhage* the nail may become loose and be shed some weeks later, but in most cases the blue-black mark gradually moves down the nail till it disappears at the tip. It takes about five months for such a mark to travel the whole length of the nail.

A jet-black discoloration of the nail occurs in diabetic and other forms of *gangrene*, but as the whole of the tip of the finger or toe is usually affected the black discoloration is not limited to the nail.

CHANGES IN SHAPE

Apart from any alteration in colour the nails may become altered in shape and size in various ways. *Clubbing* of the fingers and toes in chronic pulmonary and cardiac conditions is well known, and when that occurs the nails become curved from above downwards and from side to side. The opposite condition may also occur when the nails are either flat or hollowed

out, producing what is known as *spoon-nail* (*koilonychia*). In it the nail-plate is concave instead of being convex. In mild degrees of the condition the nail is merely flatter than normal, but in fully-developed cases the centre of the nail is concave whilst the lateral edges and free margin are slightly raised and projecting. The surface of the nail is usually smooth, but some degree of longitudinal lining may be present. The edges of the nail-plate are somewhat thickened and raised up off the nail-bed. All the nails may be definitely affected, but in mild degrees of the condition the change is limited to the thumbs and forefingers. In patients who suffer from alopecia areata a flattening or slight concavity of the nails of the forefingers and sometimes also of the middle fingers and thumbs is very common. The cause of spoon-nail is not known. It may occur in association with nutritional anemias. As most of the persons in whom it occurs are of the highly-strung type, the nervous system may play some part in the etiology.

Fragility and splitting of the nails is another fairly common condition. Some persons are born with nails which are brittle and tend to split and break off at the free ends. A similar condition may also be acquired by prolonged contact with chemicals, especially alkalis, used in the course of work. By too frequent manicuring or the application of chemicals to remove coloured nail-enamels women may cause a softening and splitting of the nails. There is also the condition known as egg-shell nail in which the nail-plate is soft, semi-transparent, bends easily and splits at the end. This particular change has been reported in association with arthritis, peripheral neuritis, leprosy, and hemiplegia. A somewhat similar condition also occurs occasionally in late syphilis, producing onychia syphilitica sicca. In this condition all the nails are affected. They are dry, atrophic and tend to split. It may be the only visible sign of syphilis, but the diagnosis can be confirmed by the Wassermann reaction.

As it has been shown that the keratin of the nail has a high sulphur content the administration of sulphur is indicated in all the atrophic conditions of the nails.

LINES OF THE NAILS

Longitudinal striation of the nails is a very common condition in adults past middle life. In slight cases it is merely an exaggeration of the normal longitudinal ridges of the nail-bed, but in well-marked cases it is accompanied by splitting of the nails (onychorrhexis) at the free margins, it is common in persons who are absorbing from a focus of infection at the root of a tooth or in the bowel.

One of the most marked cases of this condition which I ever saw was in a patient who was discovered to have a chronic abscess of the appendix. When this was opened and drained all the nails became loose, fell off and were replaced by normal smooth nails.

In addition to cases due to focal infection lining of the nails is seen in gout and nervous diseases such as neuritis and hemiplegia. It is also associated with the dry skin and scanty hair of myxoedema. Dryness of the skin, with lustreless nails showing longitudinal or transverse lining, is also seen in cases of vitamin-A deficiency. Similar changes in the nails have also been recorded in deficiencies of vitamins B and D. Administration of the appropriate vitamins in these cases will restore the nails to normal.

In all these cases, in which the splitting of the ends of the nails is marked, the condition might be confused with ringworm of the nails, in which the nails also split and break off. In ringworm all the nails are practically never affected. There are always some of the nails which are quite normal. If there is any doubt, examination of pieces of the splitting nail under the microscope will reveal the fungus in such cases.

A single raised *longitudinal ridge* running down one nail only is fairly commonly met with. This is the result of a scar at the base of the nail from previous disease or injury. As the line of the nail-fold at the base of the nail is puckered and irregular from the

presence of the scar the origin of the ridge is easily recognized. There is also a rare congenital family defect of the nails in which all the nails of the hands and feet show an atrophic condition with a definite raised longitudinal ridge running down the centre of each nail. It looks as if each nail had been gripped with a pair of forceps and squeezed so as to make the centre rise up into a ridge. This condition, curiously enough, is always accompanied by complete absence or extreme smallness of the patellæ. Why this should be and what the connection is between the nails and the patellæ is not known.

Almost as common as longitudinal lining of the nails are transverse lines, usually known as *Beau's lines*. They appear on the nails as a result of previous interference with the growth of the nail-matrix. They consist of a superficial depression running across each nail. Appearing first at the base, as the nail grows, they slowly move along the nail-bed till they disappear at the tip of the nail. As a complete nail takes from five to six months to grow, one can calculate from the position of the line when the lesion occurred. These lines may be due to a local cause, in which case all the nails are not usually affected, or to some general disturbance in which all the nails of the hands and feet are equally affected. The local causes are inflammatory lesions in the region of the growing nail-matrix as in eczema, psoriasis, general exfoliative dermatitis (especially after the administration of arsphenamine preparations), paronychia, and trauma. Of the general causes the commonest are acute infections, such as erysipelas, influenza, pneumonia, scarlet fever, measles, and typhoid fever; but any condition in which the general vitality is temporarily lowered, such as from loss of blood, especially at confinements, prolonged and severe sea-sickness, nerve shocks, epileptic attacks, exophthalmic goitre, and diabetes, may cause Beau's lines to appear. When the causative factor is repeated a succession of these lines may result and the distal part of the nail may become loose and drop off.

SHEDDING AND ATROPHY

Shedding of the nails without any previous alteration in them or in the skin around them may also occur. Certain individuals shed their nails regularly once a year for no apparent reason. Many of these cases have a family history of this peculiarity. In *epidermolysis bullosa*, in which trivial injuries give rise to the formation of large blisters in the skin, the nails frequently fall off, presumably after previous slight injuries. The nails may also be shed after fevers, especially scarlet fever, in tabes dorsalis, and in diabetes. In extensive skin diseases, such as exfoliative dermatitis, pemphigus foliaceus, extensive eczema, and alopecia areata, a similar loosening and shedding of the nails is apt to occur. In all these conditions the nails grow in again completely.

Another frequent change in the nails is atrophy. The nails become small and mis-shapen, so that only a deformed or thinned stump is left to represent them. Some degree of atrophy is nearly always present in the nails of the third, fourth, and fifth toes. This is probably due to the constant wearing of shoes. Sometimes atrophic nails may be a congenital condition in which only traces of nail substance are seen. It is usually associated with other ectodermic defects such as extreme thinness or absence of scalp hair. Such persons have difficulty, owing to the absence of the nails, in picking up small objects and doing certain forms of work such as sewing. Although not necessarily associated with any mental condition this change in the nails is fairly frequently seen in mentally defective children. It may also be an acquired condition and may follow injuries, scars from disease, frostbite, sclero-dactylia, Raynaud's disease, dermatitis, and syphilis. It also occurs in hyperthyroidism and exophthalmic goitre and has been reported after nerve injuries, in leprosy, tabes dorsalis, syringomyelia, and in prolonged debilitating diseases such as cancer. Another of the rarer causes is tetany following destruction or extirpation of the parathyroids.

In all these conditions the atrophy of the nails is permanent.

An appearance of atrophy of the nails may be produced by the patient. In cases of nail-biting the nails may be so bitten down that they look small and atrophic. The skin around them is often swollen and inflamed so that the nails appear to be sunk below the normal level and look smaller than they really are. There is also another condition allied to nail-biting which is usually seen in adults of nervous temperament. These persons are constantly picking at the free edges of their nails, so that small pieces become chipped off, making the nails much shorter than normal. In all prolonged itchy skin diseases, such as chronic eczema and neurodermatitis, the nails of the fingers may be worn down at the tips to a straight line or even show a concavity. This is due to the constant scratching. In addition to the alteration in the shape of the nails the surface becomes smooth and burnished from the constant rubbing. It is a very good index of the amount of scratching indulged in by the patient.

THICKENING AND HYPERTROPHY

The last condition which must be mentioned as of diagnostic value is a thickening and hypertrophy of the nails. It occurs in four groups: (1) simple thickening of the nail substance, (2) subungual hyperkeratosis, (3) thickening in chronic nail inflammations, and (4) onychogryphosis.

In *simple thickening* the nails become gradually thicker and thicker towards the free ends so that a very hard horny peg, greenish or blackish in colour, is produced. The surface of the nail is smooth and regular or only slightly longitudinally lined. Congenital cases of this condition have been recorded, but in chronic eczema with hyperkeratosis of the palms and soles this nail change is not infrequently seen.

In *subungual hyperkeratosis* a horny mass grows from the nail-bed and pushes up the overlying nail-plate. This change may occur by itself, but it is usually an accompaniment of a chronic skin disease such as eczema and psoriasis. If it occurs unaccompanied by a local skin eruption the possibility of its being due to chronic arsenical poisoning or general paralysis should always be remembered. The horny mass under the nail is usually fairly soft and can be scooped out. The condition must not be confused with yeast infections under the nails, in which the nail always has a dark greenish or bluish colour and the material which can be scooped out from under the nail is much softer than in hyperkeratosis. Examination microscopically and by culture will also show the presence of yeasts.

In all *chronic inflammations* of the nail-bed and infections of the nail-folds round the nails there is a gradual overgrowth of the nail substance so that the nail becomes considerably hypertrophied. This usually occurs irregularly, producing lumpy thickening of the nails. It is seen in ringworm of the nails and in all types of paronychia and naturally its treatment should be that of the condition causing it.

Of all the hypertrophies of the nail one of the commonest and most striking is *onychogryphosis*. It may affect all or only a few of the nails. In nearly all cases it is limited to the toe-nails and is especially apt to affect the nail of the great toe. Whenever it occurs on the finger-nails the practitioner should always eliminate syphilis by having a Wassermann done. In onychogryphosis the nail becomes greatly overgrown and irregularly thickened. It is usually of a brownish, greenish, or blackish colour and as it grows it becomes bent over and curved like an animal's horn. It is so hard that the patient cannot cut it, so that it is often allowed to grow to great lengths. It is found usually in elderly persons and may be associated with deformities of the toes, especially hallux valgus. It has been noted in association with peripheral neuritis, leprosy, tabes, and hemiplegia. Pituitary and thyroid dysfunctions may be responsible for a very few cases, but in the majority of cases there is no evident cause except want of cleanliness and neglect.

Ulcerative Colitis

By STANLEY O. AYLETT, B.Sc., M.B. (Lond.),
F.R.C.S. (Eng.)

(From the *Medical Press and Circular*, Vol. CCII,
5th July, 1939, p. 17)

THE many theories as to the ætiological cause of this condition and the many methods by which it is treated are indicative of our lack of knowledge of the condition and disappointing results often following its treatment. And yet, although by many it is regarded as a hopeless and intractable condition, treatment along various lines and the liberality of mind to change one specific method, if that is not suitable, will yield dramatic improvements, and often cures.

Ulcerative colitis is an inflammatory condition extending either the length of the colon or sometimes limited to its lower part only. It tends to run a prolonged and chronic course, often with sub-acute exacerbation, although the onset of the disease is sometimes acute. Death may result from complications such as hæmorrhage, perforation into the peritoneum or general exhaustion and toxæmia.

Various organisms, such as the staphylococcus, streptococcus, pneumococcus, *B. proteus* and *B. pyocyaneus*, have all been isolated from the stools, but it is very doubtful whether these are primary causative organisms or whether they are responsible for secondary invasion. There does seem no doubt, however, that the pneumococcus can give rise to a form of ulcerative colitis associated with the discharge of the rather typical greenish pus, and Lockhart-Mummery has recorded a case in which, following appendicostomy for the condition, the wound around developed an infection from which the pneumococcus was isolated.

Some of the cases have had in the past a dysenteric infection and in others, even without a previous history, the dysentery bacilli are probably the offending organisms, as treatment with polyvalent antidyenteric serum produces rapid improvement. But in the majority of cases it is impossible to find any bacteriological or serological evidence to support the view expressed by some that the dysentery bacilli are the usual cause of ulcerative colitis.

The same applies to the amœba. There is no doubt that some cases of ulcerative colitis are the result of an amœbic infection which has been missed, and Trudkin has described a case which for twenty-eight years had been treated as a non-specific ulcerative colitis but in which, by examination of material aspirated from an ulcer, the amœba was isolated. Treatment with emetine injection cleared the condition, but it is hardly fair to suggest that the majority of other ulcerative colitis cases may be due to a missed amœbic infection, especially in view of the fact that emetine rarely produces good results.

Bargen has brought forth abundant evidence that the disease is due to diplostreptococcus which in some eighty per cent of cases at the Mayo Clinic, he has been able to isolate from the bowel. In some severe cases he has been able to grow this organism from the blood, and intravenous injection of the organism has in animals, he states, produced lesions akin to those occurring in the human colon. It is fair to state, however, that many investigators believe that these lesions are not identical with those of ulcerative colitis and can be produced by the injection of a variety of organisms into the blood stream. Bargen believes that the origin of these diplostreptococci is in the upper air cavities, such as the sinuses, the tonsils and the teeth, and has isolated the organisms from such situations. It is well known that an accentuation of the disease, with perhaps death in some cases, may ensue on such operations as tonsillectomy or the extraction of teeth in cases suffering from ulcerative colitis, and this he believes to be due to a sudden liberation of these organisms which have previously been fairly well limited in these situations by the reaction of the body.

By immunizing horses against a variety of strains of the diplostreptococcus he has produced a polyvalent antiserum which, injected intramuscularly, or in severe

cases intravenously, in small doses starting with 1 cubic centimetre have produced good results. These results from the serum in other hands, however, have not been reproduced, and in an extensive trial at the Gordon Hospital much disappointment was experienced.

Some workers have tried to incriminate a deficiency in vitamins, especially vitamin A, as the causation of the disease, as there is ample evidence of the failure of the absorption of these and other essential food substances in severe cases, but, as Bargaen rightly points out, these theorists are probably putting the proverbial cart before the horse, as owing to the pathological changes occurring in the colon and the rapidity with which the whole intestine evacuates, the deficiency is the result of the condition, not the condition of the deficiency.

An attempt has been made to incriminate the internal secretions of the ductless glands, but without any definite evidence.

One thing is certain, however, and that is that worry, anxiety and shock undoubtedly increase the severity of the condition. In the September crisis we were impressed with the large number of cases which returned to the Gordon Hospital, cases which had been previously restored to a fair degree of good health. One Jewish refugee from Austria had been free from symptoms until he suddenly learnt of the removal of some of his friends by the Nazis, when immediately all his old trouble recurred.

The disease is rare in children, in whom a poor prognosis must be given, most cases occurring round about the age of thirty. Occasionally a minor epidemic of the disease is noted, as occurred recently in a prominent public school. I had occasion to see two previously-fit young men who went on a camping holiday in Scotland and drank some unboiled stream water. Both developed on their return typical ulcerative colitis, from which no specific organisms could be cultured. It seemed here that undoubtedly the source of infection was an extraneous one, probably infected water.

The patient comes up complaining of the onset of diarrhoea, associated with the passage of blood and pus, the blood sometimes being mixed intimately with faecal material, and in other cases appearing in jelly-like clots. There is often associated dull aching pain in the abdomen, but tenesmus, except in cases where the rectum is grossly involved, is conspicuous by its absence. The diarrhoea is not such in the true sense of the word, because most times it consists of the mere passage of blood and pus, and in some cases the bowels may actually be constipated. Eight to ten visits to the closet are common and, in severe cases, twenty or more may be reported each day. There is general malaise and feeling of listlessness and exhaustion, increasing anaemia and loss of weight and appetite, and all reflecting themselves in the pale, rather muddy appearance of the skin and the worried expression that the patient presents to the physician. The pulse is raised and the patient often runs a fluctuating temperature of some 100° to 101°.

Although the history is suggestive of the nature of the complaint, a thorough examination must be completed as in some cases carcinoma low down in the sigmoid, or more commonly in the rectum, gives similar symptoms. The abdomen is usually found slightly distended in both conditions, and a contracted and painful iliac colon is often palpable in ulcerative colitis. Rectal examination, if that part of the intestine is affected, will reveal to the experienced touch a saggy, rather oedematous mucosa, and, on withdrawal of the finger, it is seen to be covered with blood and pus. Sigmoidoscopy and x-ray examination should always be carried out. The former investigation is usually regarded as the province of the specialist, but a little practice in less difficult cases to examine soon gives the investigator facility with this instrument. Any of the common forms, such as Yeoman's or Morgan's, may be used, and the patient should be examined in the right lateral position, this tending to straighten out the pelvic colon. An anesthetic is unnecessary in most cases, but a preliminary washout some hours before is

of value. The essential point in using a sigmoidoscope is never to press even gently on the instrument unless the lumen of the bowel is always in view. If this point is remembered there is no likelihood of pushing the instrument through the wall of the bowel. Usually the scope can be passed to a distance of about 10 inches or so, the limit being reached at the right angled bend of the pelvic colon. Obviously, as the colon bends abruptly through 90 deg., no lumen, when this point has been reached, will be visible and no effort must under any circumstances be made to pass beyond this level.

In the early stages the bowel wall is seen to be red and inflamed with small areas of hæmorrhage and ulceration. In later stages the ulcerated areas are increased in size, oozing pus and blood, and if gently swabbed with cotton-wool granulating areas will be seen. So extensive may this ulceration be that little mucosa is left, and most of the surface is covered with necrotic tissue.

Radiologically the colon appears to be rather spastic with a loss of the haustrations normally seen, and often an irregular margin, due to the ulceration present, is observed.

It is advisable to do a blood count and hæmoglobin estimation and, in addition, a fractional test meal should be carried out as in some cases there is hypochlorhydria.

TREATMENT

The mildest of these cases should be treated with respect. Investigation of material obtained from swabbing the ulcers or examination of the faeces will eliminate such specific causes as the amoeba or the dysentery bacilli, which will respond to appropriate treatment.

There is no doubt that these cases best respond if, when initially seen, a period of bed is advised—warmth, rest and freedom from worry being essential adjuvants to recovery. The diet must not be reduced for long periods to too low a level as this will only accentuate the wasting, but nutritious low residue food given at frequent intervals should be ordered. It is argued by some that within limits the diet makes no difference, as the residue, by the time the colon is reached, from a mutton chop is probably no more than from a glass of Bengers. This may be true of the normal intestine, but where the rapidity of evacuation is so markedly increased, as in most cases of ulcerative colitis, it certainly does. Periodic confinements of the diet to fruit juice and bland fluids only for a couple of days are of value.

Various drugs may be tried, such as belladonna, to reduce the spasm of the gut, small doses of opium to diminish the constant diarrhoea, and kaolin also is of value in this respect. In those cases where constipation is an association of the condition, we have found Kaylene Ol. of value. Prontosil has been tried with apparent improvement in some patients. Red gum, gr. x, t.d.s., is also worthy of trial. In an endeavour to alter the flora of the intestine lactic acid bacilli have been introduced, and one of the best forms of administering these is by means of lactol tablets. Two of these should be dissolved in a little milk, or some milk sugar, overnight and the mixture drunk the following morning. A starch and opium enema is another method of attempting to control the diarrhoea.

The use of Bargaen's serum has been referred to and vaccines made from any diplostreptococci isolated from the bowels should be given after this. Blood transfusions in some cases work wonders.

A search should be made for any focus of infection in the teeth, the tonsils or the sinuses, but active intervention should be resisted until some alleviation of the condition has been obtained as a severe and perhaps fatal flare up may result if treated during the active phase.

There is no doubt, however, that the bulwark of treatment lies in colonic lavage, and to be of value must be efficiently carried out. A large container holding about a gallon and a half of fluid is suspended some two feet above the level of the patient's buttocks,

the patient lying on a couch in the left or right lateral position. The rubber tube from the container is connected to a large bore T-shaped glass tube the vertical limb being attached to a tube running into a bucket, and the other horizontal limb to a large bored rectal tube, which, after being greased, is inserted three or four inches inside the rectum. At first only a few ounces of fluid are allowed to run in, the tube leading to the bucket being compressed. This is then released and compression exerted on the tube leading to the container, so that the fluid runs out from the patient's rectum through the rectal tube and enters the limb of the T-shaped tube and thence into the bucket. When the washout from the lower part of the sigmoid and rectum is returned clean, irrigation is carried out farther up by allowing more fluid, up to about three-quarters of a pint, to flow in gradually, and this is then allowed to return. Never must fluid be run in to the extent of causing the patient more than slight discomfort as it is possible by so doing to rupture the bowel.

As regards the fluids used for irrigation, in the very severe types probably normal saline is best. This should be followed by such antiseptics as Albargin 2 per cent, Yatren 2 per cent, Dettol drachms 1 to 2 pints of water, or potassium permanganate in 1 in 10,000 strength. We have obtained good results in some cases using a solution of adrenalin drachms iii to iv to a pint of saline, and others report equal satisfaction using cod-liver oil. The frequency of the washouts must be controlled by the course of the disease, daily irrigations being given in the severe cases, this being reduced gradually until perhaps the patient has a treatment once or twice a fortnight.

Surgical interference, which will take the form of an appendicostomy, is advised by some at an early stage in the disease in order that the bowel can be irrigated more thoroughly, but we believe that efficient colonic irrigation in most cases is equally satisfactory. Rarer complications, such as stricture or multiple polyposis, may also require surgical intervention, but these are only seen in later cases. Perforation, of course, will require immediate laparotomy.

The treatment of this complaint will require a degree of patience and perseverance that would tax that of Job himself, but the results, if not in every case cures, are worthy of time laboriously spent.

A Study of the Economics of Pneumonia: The Costs of Diagnosis and Treatment of 625 Cases in New York City

By J. HIRSH

(Abstracted from the *Public Health Reports*,
Vol. LIII, 9th December, 1938, p. 2154)

BOTH medically and economically pneumonia is a disease attendant with serious consequences. It accounts for well in excess of 450,000 cases of illness a year in the United States, approximately 25 per cent of which are fatal. This toll exceeds that of any other communicable disease.

In an effort to determine the amount and nature of the costs of diagnosis and treatment incurred by pneumonia patients, a study of the records of 625 pneumonia cases in New York City was undertaken.

1. The median total cost of pneumonia treatment for our whole group of patients was \$34.16. Hospitalization constituted 42 per cent of the total cost for all cases; physicians' services, 28 per cent; serum therapy, 16 per cent; and other services, 14 per cent.

2. The following median costs illustrate the wide range between different types of accommodation: Ward, \$123.64; semi-private, \$183.14; private, \$224.08; home, \$93.04.

3. If the total cost is divided according to the type of services rendered, we find that for ward cases, hospital care constituted 40 per cent of the total; for semi-private, 53 per cent; for private, 50 per cent. Physicians' services comprised 22 per cent of the total ward cost; 26 per cent of the semi-private; 35 per cent of the private; and 62 per cent of the home. Serum

therapy comprised 24 per cent of the total ward cost; 11 per cent of the semi-private; 5 per cent of the private; and 10 per cent of the home. The cost of other services constituted 15 per cent of the total for ward cases; 10 per cent for semi-private; 10 per cent for private; and 28 per cent for home.

4. The median cost of hospital care for ward patients was \$50.75; for semi-private patients, \$98.45; for private patients, \$116.

5. The median cost of physicians' services in the different accommodations was as follows: Ward, \$34.60; semi-private, \$123.75; private, \$141.28; home, \$94.18.

6. The median cost of serum for those cases receiving it was: Ward, \$59; semi-private, \$85; private, \$50.40; home, \$37.50.

7. Approximately one-third of the cases studied had total costs less than \$100; another third between \$101 and \$200; one-third from \$201 to over \$451. This last group included several unusually high-cost cases, mounting to over \$1,550 in one case.

8. In the hospitalized cases, with the exception of the ward cases, the two major items of cost are hospitalization and physicians' services. The cost of the latter, however, is much less than the cost of hospitalization.

9. For the ward cases, serum therapy constituted a larger portion of the total cost than physicians' services.

10. Two major items comprise almost the total cost for home cases—physicians' services and nursing care. The reasons for this are (1) that there are no hospitalization charges, and (2) that the treatment is usually symptomatic, with the result that the expenditures for serum and other special therapies have been practically nil.

11. The large low-cost group is principally the result of the great proportion of fatalities early in the course of the disease. Seventy-six per cent of the total number of deaths in the hospitals occurred within the first 5 days.

[This abstract is included for the benefit of medical officers who receive complaints regarding the high cost of the treatment of pneumonia in India; they may find these figures useful for quoting to those who control their funds.—*Editor, I. M. G.*]

Reviews

THE BRITISH ENCYCLOPÆDIA OF MEDICAL PRACTICE: INCLUDING MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY AND OTHER SPECIAL SUBJECTS.—Under the General Editorship of Sir H. Rolleston, Bt., G.C.V.O., K.C.B., M.D., D.Sc., D.C.L., LL.D. Butterworth and Company, Limited, London. Sold in complete sets only. Cash price, Rs. 25 per volume. Also available on the instalment system at Rs. 26-8 per volume. Payable Rs. 10 monthly. Only available from Messrs. Butterworth and Company (India), Limited, Calcutta. Volume XII. Pp. xix plus 672 plus 54. Illustrated

THIS is the twelfth and, of the initial series, the last volume, but the general index and addendum is still to come, and then we are promised an annual volume of recent advances. The present volume starts with tetanus and ends with yellow fever; the Zondek-Aschheim test was described under 'pregnancy' and for 'Zoster see herpes'.

From a tropical point of view it is an important volume. There is first of all a chapter headed tropical diseases. In this Sir Leonard Rogers describes the distribution of general diseases in the tropics. This is in some ways disappointing but through no fault of the writer: over twenty years ago, before he left India, he collected data from necropsies in Calcutta which he analysed and, if this chapter is mainly based on this analysis, it is because others have not followed his example and provided the data for a more comprehensive survey. The moral however is there, namely,

that most cosmopolitan diseases which were supposed to be rare in the tropics are not rare and often more common than they are in temperate climates. Nearly every crank who has a ridiculous theory on the causation of cancer starts with the false premise that it is rare amongst coloured races, or 'natives' as he usually calls them, and the fallacy that typhoid is rare amongst Indians is dying hard, even in the best textbooks on tropical medicine. In the same chapter there are short references to 'minor tropical diseases': the 'minority' depends of course on the point of view, for chinia, which, according to the information given here, is usually fatal in 3 days, will scarcely be considered 'minor' by the sufferer. Jhin-jhinia was not included in this chapter!

Another tropical disease, undulant fever, is dealt with by General MacArthur: as abortus fever was included in the first volume, this one refers only to melitensis and suis infections. This is not an entirely satisfactory division as from many points of view suis infections go better with abortus infections. The present chapter is however a very comprehensive one and, if the writer has not been very explicit about the treatment by the sulphanilamide group of drugs, he has the excuse that they have been introduced so recently that they have scarcely found their proper place in the treatment of these infections.

There is an excellent article on trypanosomiasis by Dr. Warrington Yorke of the Liverpool School of Tropical Medicine. He has made a life study of this disease and is still actively engaged in research on trypanosomicidal drugs. Other tropical conditions included in this volume are tropical ulcer by Dr. D. N. Roy of the Calcutta School of Tropical Medicine, who gives a well-balanced account of this disease the exact aetiology of which is still doubtful, veldt sore by Dr. W. H. Craib of the Witwatersrand University, typhus fevers by Sir John Megaw, who when he was in India was a pioneer in the study of tropical endemic typhus, which is now recognized as a widespread infection in India, and who also writes on trench fever another rickettsial infection, yaws by Dr. H. S. Stannus, on whom one can always rely for a good summary, though in this instance he has been generously treated in the matter of space and has given a comprehensive account of the disease in about 30 pages, and finally yellow fever by Dr. Manson-Bahr, who has given a more concise but a very satisfactory account of this disease.

Trachoma is a disease whose distribution is largely tropical, but it also occurs in poor and sanitarially backward countries of the temperate zones. Dr. A. F. MacCallan, whose name is associated with the operation that is now widely practised for the cure in the chronic stages of this infection, is the writer of this article. We offer this criticism with the utmost respect and with the full appreciation of our lack of expert knowledge. But is it quite a fair appraisal of recent work to dismiss the sulphanilamides with the remark 'It has recently been stated that sulphanilamide and its congeners have a beneficial effect on trachoma and that they inactivate the trachoma virus. It is clear, however, that they cannot remove the new fibrous tissue which pervades and thickens the pretarsal and tarsal structures and which characterizes trachoma'. But, if they do inactivate the trachoma virus (we, in our ignorance, don't know whether this is a fact or not) surely a very great advance has been achieved, in cutting short the pathological processes and in preventing the spread of infection.

Amongst non-tropical subjects there are some very important contributions. The section on toxicology amounts to a small textbook on this subject. It is divided into two portions, homicidal, suicidal and accidental, and industrial. The growth of the second half of the section, which is the larger of the two, forms an interesting subject for a commentary on social trends since the days of the Borgias. This should prove an invaluable chapter for the general practitioner who must always be on the look out for symptoms of poisoning which may be associated with the patient's

work. In the first half of the chapter, the authors—Drs. G. Roche Lynch and D. M. Pryce—mention the traditional poison, powdered glass, only to express scepticism as to its efficacy; they refer also to powdered diamonds about which they remark, laconically, that it is 'little used now on account of expense'. Such are the results of present-day economic stress.

Another very useful chapter is on the vitamins by Dr. Leslie Harris. It is only in the specialist books on the subject of dietary that one will find this information, but there, even if the practitioner can afford to buy such books, he will not find the information so well digested and presented in the concise form in which Dr. Harris has given it in this article.

It will not be necessary to add anything further to show that this is perhaps the most interesting volume of the series, particularly from the point of view of the practitioner in this country.

ANGINA PECTORIS. NERVE PATHWAYS, PHYSIOLOGY, SYMPTOMATOLOGY AND TREATMENT.—

By H. R. Miller, M.D. 1939. Baillière, Tindall and Cox, London. Pp. xvii plus 275. Illustrated. Price, 15s.

IN this book the author has discussed the subject of anginal pain, its clinical features, nervous pathways, treatment and physiology of pain.

The book is divided into four sections; the first deals with the concept and clinical features of angina pectoris, the second describes the anatomical pathways of cardio-aortic pain, and contains a large number of excellent drawings of these pathways. These drawings form an interesting feature of the book. The third section contains the distribution or reference of anginal pain, simulation of anginal pain, and treatment of angina pectoris, both non-surgical and surgical. The fourth section deals with the physiology and psychology of pain, particularly cardio-aortic pain.

The author is of opinion 'that angina pectoris represents a powerful disturbance of the entire autonomic nervous system and that each sub-division, the sympathetic and the vagus, functions as a unit and as if its central nucleus were set into action', and 'from a chemical point of view the anginal paroxysm may be considered as partaking of sudden or excessive acetylcholine (cholinergic) mass action on whole organs and systems, evoking in the vagus and sympathetic innervations (perhaps in some of the somatic nerves as well) responses that belong to and are characteristic of each system respectively...'. To him the separation of acute coronary occlusion and non-coronary angina pectoris as entirely separate entities is an oversimplification, and he can not reconcile himself 'to a sharp distinction between coronary artery occlusion and so-called angina pectoris on the sole basis of a causative anatomical lesion in the former and merely anoxæmia of the heart muscle in the latter'.

The reviewer, who has been taught to recognize these two clinical entities as distinct from each other, does not feel convinced with the arguments of the author, and feels that, both on a clinical and an anatomical basis, the differentiation of angina pectoris from acute coronary occlusion is a necessity and the use of the term 'angina pectoris' should be restricted so as not to include conditions like acute coronary occlusion.

To the cardiologist this book will be of interest as it presents the views of one who prefers 'to consider angina pectoris a paroxysmal upheaval of central origin, and this whether the individual has normal or abnormal coronary vessels'.

PRECLINICAL MEDICINE: PRECLINICAL STATES AND PREVENTION OF DISEASE.—

By Malford W. Thewills, M.D. 1939. Baillière, Tindall and Cox, London. Pp. vii plus 223. Illustrated. Price, 13s. 6d.

THE title of this book is somewhat mysterious but it is certainly original. In this monograph the writer has tried to present an analysis of preclinical states,

i.e., conditions which may exist before the appearance of the actual symptoms and which may therefore be considered as the predisposing factors to the production of diseases. He appears to be a firm believer in the gospel 'Prevention is better than cure' and we are certainly in full agreement with him. The author thinks that by a careful study of these factors it is often possible to correct a soil which may, over a period of years, condition a person for disease. It should also be our object to discover such a soil early and correct it as far as possible so that disease may not occur, or, if it occur at all, it will not be so bad. His methods consist of recording of personal and family histories of the patient, a study of the inherited constitutional factors and a thorough examination of the patient including a proper appreciation of the minor symptoms and the application of useful laboratory tests. Suggestions for treatment have also been given. At the end of each of the long chapters there is a summary which will be welcome to all readers. An excellent bibliography, though mostly American, has been inserted at the end of the book for easy reference.

Although the author's theme is the study and treatment of preclinical states, he has, at times, transgressed considerably into the symptoms of disease. This, of course, he has explained in the preface. But while going through the pages of the book one noticed many things which the author might seriously consider for the next edition. On page 14, he calls the zygote an unfertilized egg. On page 41, he says that many cases of pneumonia ended by death on the second or third day are acute tuberculous in nature. This is difficult to reconcile with clinical experience. The author appears to have imbibed inspiration from his countrymen regarding the prevention and control of amœbiasis and says that administration of liver extracts or raw liver not only arrests amœbic process but completely eradicates the infection. Such a dogmatic statement is difficult to accept. On page 71, he makes an announcement that œdema due to organic heart disease often disappears after the use of vitamin B₁. We bow down to none in our appreciation of the vitamins, but even the worst vitamin-maniac amongst us will be surprised at this statement. On page 121 he says 'many women use pregnancy as an excuse to eat as much as they desire'. We are sure no member of the softer sex, not even of his own country, will thank him for such an uncharitable reflection. On page 153, under the heading of 'hereditary influences', the writer has included many diseases which have certainly no such relationship.

However, the author deserves our warmest congratulation for presenting a novel way of dealing with the prevention of diseases. The book contains some useful and interesting observations for which it may be recommended to those who are interested in the preventive aspects of human diseases.

M. N. D.

THE SCHIZOPHRENIFORM STATES—A KATAMNESTIC STUDY BASED ON INDIVIDUAL RE-EXAMINATIONS—WITH SPECIAL REFERENCE TO DIAGNOSTIC AND PROGNOSTIC CLUES AND WITH A VIEW TO PRESENTING A STANDARD MATERIAL FOR COMPARISON WITH THE REMISSIONS EFFECTED BY SHOCK TREATMENT.—By G. Langfeldt, M.D. 1939. Oxford University Press, London, Humphrey Milford. Pp. 134. Price, 10s. Obtainable from Oxford University Press, Bombay and Calcutta

THIS brochure embodies further research on the part of the author into the problem of schizophrenia and is a sequel to his former publication, *The Prognosis in Schizophrenia*, a review of which appeared in the *Indian Medical Gazette* in 1938. Like its precursor, the present work is one of extreme importance. The author's research took the form of a personal examination of 100 cases discharged from the University Psychiatric Clinic in Oslo, at the most twelve and at the least six years after their discharge. The object of the investigation was to try to ascertain what cases show spontaneous remission without treatment and what cases, by virtue of the manner of their

development and symptomatology, yield a poor prognosis. The author refers to the work of Jacobowsky, Rian and Soininen in which it was shown that those suffering from a typical schizophrenia, that is to say, showing symptoms with manic-depressive features as well as a strong hereditary taint, give the best results. On the other hand, the typical endogenic 'process psychoses' (by which term the author means to indicate schizophrenic conditions characterized by a severe depersonalization syndrome without mental 'cloudiness') do not seem to react favourably to shock treatment. This discovery reveals this modern treatment of schizophrenia in quite another light than that in which it has hitherto been regarded. The author feels convinced from his observations that in many clinics and hospitals patients are treated in an uncritical manner and that frequently to their detriment. The author's conclusions include the opinion that a leptosome body, schizoid character, insidious onset, lack of a precipitating factor, are all unfavourable factors as regards prognosis. On the other hand, a pyknic body, an acute onset, demonstrable exogenic factors and a non-typical 'schizophreniform' symptomatology, particularly the presence of manic-depressive features are, from the standpoint of prognosis, favourable features. Further, the author's observations definitely show that insulin and cardiazol treatment has the effect of only shortening the time taken to recover in certain cases, namely those in which there is severe depression or in which there is cloudiness and incoherence. As in the former brochure the reader finds peculiar words such as 'delir', 'debil', 'intervenient', etc.

O. B-H.

A SURVEY OF CHILD PSYCHIATRY CONTRIBUTED BY CONTEMPORARY BRITISH AUTHORITIES.—

Edited on behalf of the Child Guidance Council by R. G. Gordon, M.D., D.Sc., F.R.C.P. (Ed.). Oxford University Press, London, Humphrey Milford. Pp. xii plus 278. Price, 10s. 6d. Obtainable from Oxford University Press, Bombay and Calcutta

THIS book has been edited by Dr. Gordon on behalf of the Child Guidance Council introduced into Great Britain by the trustees of the Commonwealth Fund of America, ten years ago. At the present moment there are over fifty clinics in active work so that such a thing as child guidance is now accepted by most persons concerned with judicial, educational or social work throughout the country. No less than twenty-one authors have contributed to the book and the reader is presented with a reasonably coherent survey. In his own contribution to the book, Dr. Gordon quite rightly deplores the attitude of the average doctor towards psychiatry. Far too few doctors realize the importance of trying to correlate anatomy, physiology and physical pathology with psychiatry. As Dr. Gordon observes, one of the most important fields of medical research is psychosomatic disease, that is, the production by deranged emotional states of symptoms and syndromes regarded hitherto as essentially physical in origin. As examples of conditions due to deep-seated emotional conflict and distress, Dr. Gordon cites asthma, peptic ulcer and diabetes. Dr. D. W. Winnicott contributes a very interesting article on the psychology of juvenile rheumatism in which he discloses in a very unusual degree an understanding of the effect of 'being ill' in terms of unconscious fantasy. Further, Dr. Winnicott points out how pains and joint troubles can result from the direct action of local and general excitement, acute and prolonged, and of anxiety and rage. He maintains that the common aches and pains of children and grown-ups can be traced to the dramatization of persecutions belonging to unconscious fantasy of what is inside the body. Dr. W. Moodie contributes a valuable study of anxiety in children and adolescents. Dr. Emanuel Miller, an eminent child psychiatrist, is responsible for an illuminating study of obsessional and compulsive states in children. Dr. W. Paterson Brown writes of

what he terms 'the family neurosis' in which he shows to what extent the family is responsible for the creation of a neurosis. He regards the family neurosis as endowed with certain well-defined clinical features and that the mother is the centre-piece of the neurosis, while it is to the father that we must turn when considering the prognosis and treatment. Space does not permit of detailed reference to each contribution to this book, but there can be little doubt that it serves to bring to the notice of the medical profession, particularly the family physician, that the ordinary medical curriculum to-day does not yet afford facilities for acquiring enough psychological knowledge to render the general practitioner of much use in situations of the type here discussed. In India, medical curricula are even more deficient in respect to imparting instruction in psychological medicine than the medical curricula of Europe and the United States, hence this book should be a most valuable addition to the library of doctors trained in medical schools and colleges in this country.

O. B-H.

PERSONALITY CHANGES AFTER OPERATIONS ON THE FRONTAL LOBES—A CLINICAL STUDY OF 32 CASES.—By Gösta Rylander. 1939. Oxford University Press, London, Humphrey Milford. Pp. 327. Illustrated. Price, 15s. Obtainable from Oxford University Press, Bombay and Calcutta

THIS brochure embodies a report on an investigation into the nature of the changes which supervene after partial excision of a frontal lobe. Hitherto reports published on this topic have been extremely varied and frequently contradictory. For the sake of consistency in the technique and the method of judging the cases, consideration had to be paid to special points. For example, complications such as frequent convulsions before or after operation could not be accepted, because of the risk of epileptic disturbances in the character. Patients still suffering from severe aphasic troubles had also to be excluded, because of the necessity of a special method of investigating them and the obscure connection between aphasia and intellectual disturbances. The number of patients chosen amounted to 32. Of these, 31 had been operated on for tumours and 1 for an abscess. In 20 of the cases, the operation involved the left frontal lobe and in 12 the right. With regard to the type of tumour, 12 of the patients had a meningioma and 19 a glioma. The follow-up examinations were carried out from six months to seven years after the operation in the patients' homes. First of all the pre-morbid personality was reconstructed with the help of all available information. With this as a background the post-operative cogitation was then analysed from three different points of view. First, a special scheme was followed containing questions on the patient's life, memory, comprehension, initiative, endurance, working capacity, judgment and general interests. The second step was to analyse the operative sequelæ from the standpoint of the patient himself. The third point of view from which the patient's condition was considered was that of the author himself.

The conclusions drawn from this investigation are that mental changes do occur after excision of parts of the frontal lobe which exhibit themselves in an alteration of personality. Generally they are not of such a degree as to destroy the subject's ability to lead a normal social existence, but they can be fatal to persons doing qualified intellectual work. The brochure is supplied with a copious bibliography pertaining to the matter under consideration.

O. B-H.

MODERN CLINICAL PSYCHIATRY.—By Arthur P. Noyes, M.D. Second Edition. 1939. W. S. Saunders Company, Philadelphia and London. Pp. 570. Price, 22s. 6d.

PSYCHIATRISTS and students of psychological medicine the world over will welcome this second edition of Dr. Noyes' textbook. Each chapter is provided with

a bibliography of its own which is a highly convenient procedure. The pharmaceutical treatment, particularly that involving the administration of convulsant agents, has been brought up to date. The author's views on the therapeutic value of 'shock' treatment are very cautiously expressed. The author holds that psychiatry should be integrated with medicine in all its branches and that artificial distinctions between body and mind should be obliterated. That it should be necessary to-day to emphasize this fundamental principle shows how bad an ear mankind has for new music, although, it must be admitted, this tune is not, after all, so very new. Many psychiatrists have been playing it to their medical, surgical and gynaecological colleagues for at least twenty years. 'How long, oh Lord, how long'?

O. B-H.

MODERN TECHNIQUE IN INFANT FEEDING.—By Lalit K. Mitra, M.B. (Cal.), L.M. (Dub.), D.C.H., M.M. (Lond.). 1939. Published by the author from Child's Clinic, 10, Chowringhee Road, Calcutta. Pp. 133. Price, Rs. 4-8

DR. MITRA has written a book of convenient proportions covering the practical gambit of infant feeding, which may well serve as a guide to the young practitioner embarking on the stormy sea of pædiatrics in India.

The chapters on growth and nutrition of the infant are excellent and the remainder of the text is devoted to a presentation of the more conservative methods of infant feeding.

One might perhaps wish that test feeding and lacticization of cow's milk were given greater prominence: the one as an important guide to the management and adequacy of breast feeding, and the other as an invaluable corrective to minor digestive disturbances during the early months of dentition.

The principle of breast feeding after the sixth month by the middle-class mother in India is open to argument. To many of us who see the effects upon mother and child it is regarded as an economic necessity rather than 'a consummation devoutly to be wished'.

L. G.

AIDS TO ORGANIC CHEMISTRY.—By Stanley F. Smith, M.B., B.S. (Lond.). Second Edition. 1939. Baillière, Tindall and Cox, London. Pp. viii plus 120. Price, 3s. 6d.

THIS handy little volume belongs to the Students' Aid Series which includes many other books on scientific subjects and on almost every branch of medicine. The book is primarily intended to help the student over his initial troubles and then supply a short summary suitable for rapidly reviewing the essentials.

It is divided into 36 chapters, most of which are quite short. The preparation, properties and reactions of most of the important organic compounds are explained briefly by means of equations and structural formulæ, and the student has to study it along with some standard textbook. It is, however, remarkable how the whole of organic chemistry can be revised by a medical student with the help of this book in the course of a few hours and it may truly be said to have bridged the gap between the student and a larger textbook.

S. G.

HUMAN PHYSIOLOGY: A TEXTBOOK FOR HIGH SCHOOLS AND COLLEGES.—By P. Goldthwait Stiles. Revised by G. C. Ring. Eighth Edition. 1939. W. B. Saunders Company, Limited, Philadelphia and London. Pp. 450. Illustrated. Price, 10s.

THE sub-title of this book 'A Textbook for High Schools and Colleges' indicates its scope.

In the reviewer's opinion it completely fulfils its object because it is clearly and simply written and

the many similies exemplified by everyday objects and experience are apt, so that they help to explain in a simple manner the various functions of the body.

It is a book that can be recommended without reserve, because it is felt that any senior school boy or girl who reads this book carefully will have a sound general knowledge of his or her bodily functions.

HEALTH BULLETIN, NO. 18. MALARIA BUREAU, NO. 9. A PRACTICAL ENTOMOLOGICAL COURSE FOR STUDENTS OF MALARIOLOGY.— By P. J. Barraud, F.R.E.S., F.L.S. Second Edition. Revised by I. M. Puri, M.Sc. (Punjab), Ph.D. (Cantab.), F.R.E.S. Published by the Manager of Publications, Delhi. 1939. Pp. 143, with 18 plates. Price, Re. 1-12 or 2s. 6d.

The scope of this invaluable Health Bulletin is expressed in the first few words of the introduction.

'The *Bulletin* has been prepared more especially for use at the malaria classes of the Malaria Institute of India. It is hoped, however, that it may be helpful as a guide to others who may wish to organize malaria classes elsewhere, especially under Indian conditions. The details of practical work and field work, together with the illustrations and explanations, may also prove of practical assistance to workers in the field who may be prevented from attending classes on the subject'.

The book has served its purpose admirably for a number of years and has been used extensively in India, not only by students but by those who have undertaken to train anti-malarial personnel. It was written originally by Mr. Barraud, a former entomologist to the Malaria Institute of India, and is now completely revised by Dr. Puri who holds this appointment at present. This important publication certainly maintains its high reputation.

Abstracts from Reports

THE ROCKEFELLER FOUNDATION, NEW YORK. ANNUAL REPORT FOR THE YEAR 1938

PRESIDENT'S REVIEW

The year in brief

DURING 1938 The Rockefeller Foundation appropriated a total sum of over \$15,000,000. Of this amount, speaking in terms of rough classifications, \$3,800,000 was given to the medical sciences, \$3,800,000 to the social sciences, \$3,000,000 to the natural sciences, \$2,500,000 to public health, \$1,000,000 to the humanities, and \$300,000 to rural reconstruction in China.

The Foundation's income during 1938 amounted approximately to \$7,000,000. In appropriating \$15,000,000 it was necessary, therefore, not only to use up the balance carried over from earlier years, but to dip into the principal fund to the extent of \$3,755,000.

In carrying out its 1938 programme the Foundation operated in forty-two countries in all parts of the world. Eighteen of these countries were in Europe, five in Asia, two in Africa, five in South America, ten in North and Central America and the West Indies, and two were islands of the Pacific.

YELLOW FEVER

Two years ago in this review it was reported that jungle yellow fever, spread by some vector other than the *Aedes aegypti* mosquito, had been discovered in wide areas of South America. In the last two years outbreaks of this disease have been observed from 7° 30' North Latitude to 27° South Latitude; from the eastern slope of the Andes to the mouth of the Amazon; at altitudes varying between sea level and 5,000 feet; in regions of dense jungle growth and in prairie districts where the infected forests cover not more than 5 per cent of the land area; in sparsely populated regions and in heavily populated agricultural districts; in the form of epidemic waves and under conditions suggesting permanent local endemicity. Jungle yellow fever has proven to be not only a constant source of virus for the reinfection of towns but also an important public health problem in its own right.

In any discussion of jungle yellow fever emphasis must be given to the fact that this term is one of epidemiological significance only. Clinically, pathologically, and immunologically, it has so far been impossible to differentiate jungle yellow fever from the classical *aegypti*-transmitted variety.

Field observations have, during the past four years, failed to indicate that any of the minor *aegypti*-transmitted outbreaks during this period have been due to virus coming from a previous *aegypti*-transmitted infection. Rather these observations have suggested

in each instance that the town had been invaded by a virus from near-by jungle districts. Were it not for the existence of the jungle infection, yellow fever might have disappeared permanently from the Americas in 1934. Although the clinical picture of yellow fever is the same whether the infection develops in the town or in the jungle, the epidemiology of the two types is quite different. *Aegypti*-transmitted yellow fever is generally acquired indoors; it tends to involve all non-immunes of all ages living in infected houses, and spreads from place to place along the routes of human travel. The disease follows a mosquito-man-mosquito cycle and is easily controlled by reduction of the numbers of the mosquito vector.

Jungle yellow fever, on the other hand, is usually acquired in or at the edge of the forest during working hours by those whose occupation takes them to the woods. It does not tend, in the absence of *aegypti*, to involve other members of the household living under the same roof with infective cases. The disease in man is apparently an accidental one occurring in the course of some cycle of infection in the jungle of which man is not an essential part. The infection apparently spreads throughout jungle areas without relation to routes of human travel. The only reasonable hope of prevention lies in individual immunization by vaccination.

A year ago the Foundation announced the successful development in the laboratories of its International Health Division of an effective virus (known as 17 D) for vaccination against yellow fever. By the end of 1937, 40,000 persons, largely in Brazil, had been vaccinated, and subsequent tests showed that full or partial immunity had been acquired in over 90 per cent of the cases. During the week ending 10th December, 1938, the number of people vaccinated passed the million mark, the total for the year being 1,059,252. The wide use of virus 17 D among exposed populations during active outbreaks of jungle yellow fever in 1938 has resulted in a mass of field observation almost as conclusive as laboratory experiments. Local physicians and field workers report a sudden reduction in observed cases in infected districts shortly after mass vaccination and cite instances in which individuals who failed to be inoculated contracted the disease later in infected forests, while vaccinated members of the same groups escaped. Field experience suggests that the protective effect of vaccination begins not later than a week after inoculation, although laboratory tests fail to show demonstrable antibodies as early as this.

The duration of the immunity induced by virus 17 D can be determined only by future studies. Of twenty-one persons whose blood was tested one year after vaccination, nineteen were found to be still immune. Monkeys vaccinated two and a half years ago are still completely immune.

While vaccination promises to be of great aid in preventing the transfer of yellow fever by the human host from one locality to another, it cannot of course eliminate the virus in the jungle nor block its dissemination through contiguous forests in the tropics. Lurking somewhere in these forests are unknown vectors and other hosts than man; and a great deal of work remains to be done before they can be accurately identified.

No case of aegypti-transmitted yellow fever was observed in any locality in the Americas in 1938. This is the result of hard-won knowledge and eternal vigilance. As one looks back to the early beginnings of the fight against yellow fever under the leadership of pioneers like Walter Reed and Carter and Finlay and Gorgas, it is possible to see how great the advance has been. We know now that the solution of the mystery is much more complex than Reed and his associates imagined. But although yellow fever is still a serious public health problem, there are substantial grounds for believing that the battle is at least half won. Unless the disease should break out in some country like India, for example, where it has never before been found, the future would seem reasonably assured.

THE THREAT TO THE WESTERN HEMISPHERE

Anopheles gambiae, from Equatorial Africa, has invaded South America and is making itself very much at home in Brazil.

Until 1930 this species of mosquito was not known on this side of the Atlantic. In that year, however, or shortly before, it crossed the ocean, apparently by airplane or on one of the fast French destroyers which at that time were working in connection with the French air lines between Dakar in West Africa and Natal in Brazil. The species was first discovered in 1930 within the city limits of Natal by a member of the Foundation's staff, during a routine mosquito survey in connection with the yellow fever service. The seriousness of its presence was immediately recognized, but it was hoped that the invasion might be localized by natural conditions unfriendly to the invader.

These hopes were disappointed. In 1930 and 1931 there occurred in the vicinity of the breeding area in Natal an outbreak of malaria of a severity unprecedented in the annals of the city. The Yellow Fever Service was compelled to undertake gambiae control in order to maintain an efficient staff for its own work. By 1931, following prevailing winds, gambiae mosquitoes had travelled up the coast 115 miles. Two years of severe dry seasons seemed to check the invasion, and then, with the recurrence of normal rainfall, the onward flight started again.

In recent years severe epidemics of gambiae-carried malaria have occurred in localities over two hundred miles west and north of Natal.

In its public health work The Rockefeller Foundation maintains its own scientific staff. While it supports, through grants, the public health activities of other institutions, for the most part it pursues its own programme in the field, operating on a world-wide basis. This programme dates back to the creation of the Foundation in 1913—and even earlier, through the activities of the Rockefeller Sanitary Commission.

A recent writer has suggested that scientific research should not be left to the uncertainty of private philanthropy but should be made a responsibility of the government. Without attempting to argue the theory implied in this broad contention, it is interesting to analyse what is happening in the field of medical research. While exact statistics are wanting, it seems evident from those available that tax sources to-day in the United States are providing as much money for research in medicine as all other sources put together, excluding industry, but including private hospitals and universities, foundations, and individual donors.

TASKS AHEAD FOR MEDICINE

The reason that The Rockefeller Foundation, in the medical sciences, is concentrating its efforts on mental

hygiene is because it believes that at the moment that field represents one of the most underdeveloped areas in all medicine. Cases of mental and nervous diseases occupy more hospital beds in this country (U. S. A.) than all other diseases combined.

But with all the need that exists in this field it would be foolish to shut one's eyes to the fact not only that other fields are also backward but that science is on the threshold of great events in medicine; adequate support in a dozen different areas might well bring results of incalculable benefit to human health and welfare.

During 1938 the Foundation made a number of grants for the development of projects in the new field of 'molecular biology'.

The Foundation's largest commitment during 1938 in the field of the natural sciences was a conditional appropriation of \$1,500,000 to the University of Chicago toward the establishment of a \$2,000,000 endowment fund for research in the biological sciences. To provide for the support of biological research during the three years in which the University is raising its share of the permanent fund, the Foundation made an additional grant of \$180,000. The Division of Biological Sciences of the University of Chicago occupies a prominent position in American science. Its field is a wide one, the departments of biochemistry, physiology, anatomy, pharmacology, bacteriology, and psychology, as well as zoology and botany, co-operating to develop a balanced and integrated research programme.

Harvard University was given \$100,000 for expenditure over seven years toward the cost of research in the Department of physical chemistry in its Medical School. This study will provide quantitative data on the chemical and electrical behaviour of proteins and lipoids. A grant of \$75,000 was made to the University of Illinois in support, over five years, of studies in nutrition, with particular reference to the function of the amino-acids. The University of Stockholm was given \$37,400 for its institute of experimental biology. A grant of \$40,000 was made to the Roscoe B. Jackson Memorial laboratory at Bar Harbour, Maine, toward the cost of a building to house the laboratory's unique stocks of specialized and standardized mice, which are supplied to research workers throughout the country.

THE RETREAT FROM REASON

To speak of research in the field of international relations in such an anxious and disillusioned hour as this may seem almost like a jest. Everywhere reason is on the defensive and we live in danger that mass hysteria will completely overwhelm it at a time when it is most needed as a safeguard. If there have always been wars and rumours of wars, never before has there existed the possibility of such material havoc and cultural disintegration. It may be, as a recent writer has said, that this arid period in which we are living is the watershed between two forms of civilization, and that the future beckons to a Promised Land more pleasing than we dream. This optimism is creditable, but for the moment at least the world is facing a cultural crisis in which reason is everywhere in retreat.

Never has there been a greater need of intelligent understanding of the social forces that are moulding the future. Such an understanding must be based on realities, and not on intuition or wishful thinking. If the problems arising out of human relations are to be solved at all, it will be through the same scientific approach to facts, made in the same dispassionate spirit of inquiry, which has given man command over his physical environment. That this course presents infinite difficulties no one will deny, but along this road lies the only ultimate hope.

Acting upon this faith, which to some may seem to burn with a feeble flame, many devoted organizations throughout the world are working directly on the problem of international relations, and The Rockefeller Foundation has been glad to continue its support in this field.

[These few extracts from that portion of the President's review which deals with medical matters

are all that we can find space for. They will we hope indicate to some extent the scope of this remarkable foundation in the branches of its work that is of chief interest to medical men.—Editor, I. M. G.]

ANNUAL REPORT OF THE PUBLIC HEALTH COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1937. VOL. I

With a deeper realization of the importance of public health problems, there has begun to arise a new determination to combat ill health and suffering by organized effort, and this national awakening to realities is one of the most hopeful developments any public health officer could desire to witness.

'The public health movement in India has now gained a considerable momentum and may be expected to effect in increasing measure its true purpose, that of improving the physical well-being of the people of India and of enlarging their capacity for enjoyment of life'.

The primary requirement for improving the public health is the provision of trained health staffs in urban and rural areas. The transference of public health to Provincial Governments after the Government of India Act of 1919 was followed by a steady progress in this direction, the desire for improvement is to be found everywhere, and it may be confidently anticipated that health staffs will gradually be provided all over the country.

Decentralization of public health administration has necessitated the creation of an organization whose object should be to co-ordinate provincial activities and to promote a greater and more uniform advance of public health in India. For these purposes the Central Advisory Board of Health has been inaugurated. While no statutory functions have been assigned to the board, the discussions which have taken place at its two meetings have shown that its proceedings command a wide interest.

A special committee appointed by the board has issued a comprehensive report on 'Maternity and Child Welfare Work in India'. Other committees have been entrusted with the task of investigating other important problems such as 'leprosy control', 'food adulteration' and 'inoculation of pilgrims attending festival centres'.

In addition, the board has recommended to the provinces the desirability of investigating, by means of local joint committees, common public health problems affecting civil, railway and military populations, while discussions on other matters of inter-provincial concern, such as controlling cholera epidemics, have also taken place. Thus it may be seen that the scope for the activities of the board in co-ordinating public health work all over the country is immense, and it may be expected that its usefulness will grow with the lapse of years.

The importance of rural health has been increasingly recognized in India within recent years. The transference of wide powers to the provinces and the extension of the franchise in order to make provincial Governments more responsible to the people, have produced a common desire to attack the problems of social ill health on a wide front, in which economic uplift, improvement of health, reform of the system of education and other ameliorative measures all find a place. Fresh efforts have been made to extend rural medical relief, provide safe village water supplies, better sanitation, maternity and child welfare work, and to wage special campaigns against diseases such as malaria, tuberculosis and leprosy.

In the field of rural hygiene, the application in this country of costly sanitary methods is outside the bounds of practical politics, because of the immensity of the population and areas to be covered. Organizations known as 'health units' have been established in four or five provinces with financial assistance from the Rockefeller Foundation, and in these areas considerable progress has already been achieved.

It is hoped that these activities in limited areas will be the precursors of more widespread health work in different parts of the country.

It is not generally recognized that, in medical research, particularly in tropical diseases, a long record of successful achievement stands to India's credit.

The research institutes maintained by the Governments in India, the members of the Medical Research Department of the Government of India and the Indian Research Fund Association have been responsible for the high place India has secured for herself in the field of medical research.

The three important international organizations with which India is closely connected in the sphere of public health and port quarantine are the International Public Health Office, Paris, the Health Organization of the League of Nations, Geneva, and the League's Eastern Bureau at Singapore.

India is still regarded with suspicion as a reservoir of infection for such diseases as smallpox and cholera, and it is of great importance to her overseas trade that this suspicion should be dispelled as soon as possible. Considerable advance in port health organization and in control of infectious disease has been made within the past few years.

Another direction in which marked progress has been made is in the field of nutrition. The Indian Research Fund Association recognized the importance of sound nutrition of the people many years before the subject was taken up by the League of Nations and by the Governments co-operating with that international body. The contributions made by Sir Robert McCarrison to this science are now seen to be much more generally applicable than was originally realized.

In more recent years, the practical aspects of the nutrition problem have received greater attention. By laboratory studies of the common foodstuffs and the actual diets consumed by the people, and by field studies for ascertaining the nutritional state of the people, much information has been collected which is invaluable for the betterment of national nutrition. Further, researches have demonstrated the advantages of adding milk, even skimmed milk, to the ordinary unsatisfactory diet of many people, while the common deficiency of vitamin A in the diet can be corrected by taking red-palm oil which can be produced in India. From the practical point of view the importance of these researches is immense, because the nutritional state of the people can be improved only by methods which are cheap.

To better the nutritional state of the people it is essential to correlate nutritional researches with the activities of animal husbandry and agricultural departments. For this purpose a liaison officer trained in human nutritional work has been appointed and it is his duty to keep in touch with all provincial agricultural and animal husbandry departments. Further, a National Nutrition Committee has been appointed which includes nutrition workers, representatives of agricultural and husbandry departments, and expert educational and economic advisers.

The population problem

Special committees in provinces to study the population problem and educate the public are recommended.

While the birth rate has shown little change since 1891, the death rate has been falling since 1921. The average annual increase during 1921-30 was just under two millions. During the succeeding seven years, which were free from violent outbreaks of epidemic disease, the average yearly increase of population in British India is estimated at just short of three millions. These facts support the inference that the present decade is likely to present an even larger rate of increase than that recorded during 1921-31. During the period, 1921-31, the increase of population in India was approximately 34 millions while the indications are that during 1931-41, the increase will in all probability be 45 to 50 millions.

The continuing low standard of living and the rapid expansion of numbers that have characterized the

present and preceding decennia are facts which must be faced. Into this complex situation another important factor has been introduced in the form of a preventive health campaign which, in spite of serious deficiencies, has already saved increasing numbers of human lives. No civilized government can turn back on an expanding programme of public health endeavour, so that it is all the more essential for thoughtful men and women to turn their attention to the study of the population problem.

In the words of Sir John Megaw, 'What is required, is education of the whole community in life planning. The people must be made to realize what they are up against, and how they can control the forces of nature to their own advantage. The best brains of India helped by the best brains of the outside world will be needed. Experts in agriculture, education, public health, economics and industry must co-operate in deciding what should be taught; then the subject-matter must be prepared in a form which will be palatable to the masses'.

Maternal deaths

At least 200,000 women die every year in India from causes arising from child-bearing. In 1937, deaths of infants under one year of age accounted for 24.8 per cent of the total mortality at all ages, of children under five for 18.6 per cent, and of those between five and ten years of age for 5.4 per cent. Corresponding figures for England and Wales in 1936 were 7.1 per cent, 2.5 per cent and 1.2 per cent.

Maternal mortality enquiries conducted in limited areas suggest that, for India as a whole, about 20 women die among 1,000 undergoing pregnancy and childbirth.

Accumulating evidence seems to indicate that child-bearing takes a much higher toll of life in urban than in rural areas and that the good effects of the better urban facilities may be more than outweighed by the ill-effects of overcrowding, of lack of sunshine and fresh air and of ill-balanced diets. Few reliable figures for maternal mortality are available for rural populations, but the maternal mortality rate recorded in three 'health-unit' areas in South India was only 5.0 per 1,000 total births.

The increasing concern at this enormous loss of life and the heightened sense of responsibility for the health and safety of mothers and children were reflected in the decision of the Central Advisory Board of Health in 1937 to appoint a special committee to report on the whole subject of maternity and child-welfare work in India. The committee completed its work recently and its comprehensive report has now been approved by the board and has been issued.

The report stressed the importance of appointing a properly qualified and experienced woman medical officer in each province for the efficient administration of maternity and child-welfare work.

The employment of women doctors in the management and supervision of municipal and other local maternity and child-welfare schemes is also urged. For the benefit of the mothers and children requiring advice and assistance, a woman doctor's services are essential, because there are limitations to the employment of non-medical women in the welfare centres.

Another recommendation refers to the desirability of providing a system of grants-in-aid from Government sources, not only because these stimulate local bodies to improve their services but because they give official public health departments a suitable measure of control and supervision over the work undertaken by local authorities.

Further advance has been made by the recent passing of a number of provincial Nurses', Midwives', and Health Visitors' Registration Acts, designed to secure the registration and better training of midwives and health visitors.

A sound training in pre-natal and post-natal care is essential both for medical students and midwives. For this purpose, well-organized pre-natal and post-natal clinics should be provided in all hospitals training students and midwives, and attendance at these

clinics should be included in the courses of instruction in midwifery for medical students.

The organization of maternity and child-welfare work in India has, in the past, been largely due to voluntary effort. The stage seems to have been reached when transition from voluntary direction to official control must take place if further developments are to be made, and the problem during the next few years will be to preserve a proper balance between government and voluntary effort.

Causes of death

'Fevers' alone accounted for over 3,000,000 deaths or 55 per cent of the total mortality, and respiratory diseases for 8 per cent in 1937. The large figure for 'fevers' almost certainly includes over a million due to malaria and large unknown numbers due to typhoid fever and tuberculosis.

Existing agencies for the registration of vital statistics in rural areas make it impracticable to carry out classification of the causes of death except in a few large groups and, apart from such diseases as cholera, smallpox and plague with which the people are familiar, other deaths are ordinarily recorded as 'fevers', 'respiratory diseases' and 'other causes'. So true is this that nearly 93 per cent of the six million and odd deaths registered during 1937 were placed in these three groups.

In comparison with these diseases deaths from cholera, smallpox and plague are of relatively minor importance, though in the popular imagination these three are the most dreaded epidemic diseases. In fact, during the period 1925-37, the combined mortality from these three diseases did not exceed, in any year, 10 per cent of the total recorded mortality.

Malaria, tuberculosis and leprosy have, within recent years, received increasing attention from health authorities and voluntary organizations in the country. Provincial public health reports show a general recognition that malaria constitutes the major health problem in most provinces. The rural malaria death rate is approximately three times the urban rate and, as nearly 90 per cent of the population is rural, the problem is urgent.

The general policy in the provinces is to provide an adequate supply of quinine or cinchona febrifuge, to popularize the use of these drugs as far as possible by means of propaganda and teaching in the schools, and to provide extra medical staff and travelling dispensaries to localities visited by regional epidemics.

Regarding tuberculosis, the last decade has recorded considerable progress in organized effort. In 1929 a central organization came into being when various schemes were considered for the utilization of the King George V Thanksgiving Fund. It was decided that this fund should be devoted to a campaign against tuberculosis and the King George Thanksgiving Fund Anti-Tuberculosis Committee was constituted. With an annual income of only Rs. 53,000 the activities of the committee were necessarily restricted.

The special appeal for funds for fighting tuberculosis which was issued in the name of the King-Emperor by Her Excellency the Marchioness of Linlithgow in December 1937, has met with an excellent response and has made it possible to organize the anti-tuberculosis campaign on a wider basis. The Tuberculosis Association of India was formed a few months ago, incorporating the King-Emperor's Anti-Tuberculosis Fund and King George Thanksgiving Anti-Tuberculosis Fund.

The inauguration of the Indian Council of the British Empire Leprosy Relief Association in 1925 was a distinct advance in the campaign against leprosy. A capital fund of Rs. 20,25,000 was created by an appeal to the country and the annual income from this fund, amounting to nearly a lakh and a quarter, was made available for furthering anti-leprosy work in all directions. Later, a further donation of Rs. 3,13,000 was received from Their Majesties' Silver Jubilee Fund. The demonstration that early cases of leprosy were amenable to treatment also helped towards awakening public interest and towards the organization of effort to combat the disease.

Research work has been carried on at the School of Tropical Medicine, Calcutta, in co-operation with the authorities of the School and the Indian Research Fund Association. This work has been carried out at a cost of Rs. 3,37,000 up to the end of 1938, and the results obtained have been published in the annual reports of the Association as well as in scientific journals in India and abroad.

Food adulteration

Adulteration of common articles of food is widely practised in India and the subject has not received the attention it deserves. Milk and milk products are everywhere adulterated. In one province, 73 per cent of the samples of *ghee* examined, 50 per cent of the samples of milk and 40 per cent of the samples of butter, were found to be adulterated. One of the causes of this unsatisfactory state of affairs is the apathy with which the public view the matter.

Health in schools

The importance of a well organized school medical service in a national health programme requires no special emphasis. 'Medical Science has proved with unmistakable clearness that disease and incapacity in adolescence and adult life find their source, all too often, in the seed time of childhood. It cannot be doubted that much of the excess of sickness and mortality under forty years of age must be attributed to this origin and some of the maternal mortality, some of the recruits rejected on physical grounds, some of the lost time in industry, some of the lack of resistance to infective disease may all derive from this same source'. These words of the Chief Medical Officer to the Board of Education, England, and Wales, are equally applicable to India.

Fairs and festivals

Within recent years the sanitary control of pilgrim centres has received increasing attention from provincial health authorities. The measures taken for this purpose have, in fact, reduced to a great extent the danger of explosive outbursts of cholera, although it must be remembered that, as in the extensive epidemic that followed the Hardwar Kumbh Mela in April 1938, large festivals with their inter-provincial traffic in pilgrims, who have often to pass through endemic regions of cholera, always hold out a threat of outbreaks. However, the general effect of precautionary measures now being taken has been satisfactory, for during 1937, all fairs and pilgrimages in the provinces of British India passed off without any serious outbreak of infectious disease in epidemic form.

The problem of health education in India is complicated by the fact that the majority of the population is illiterate. Moreover, there exist certain age-long customs and habits which cannot be easily changed. Instances are the indiscriminate pollution of village sites with nightsoil and the indifference of the people to contamination of their water supplies. It is difficult to convince the villager that, in respect of many diseases, man is his own worst enemy and that a radical change of habits is essential if sickness and mortality arising from avoidable diseases are to be prevented.

ABSTRACT FROM THE ANNUAL REPORT OF THE INDIAN RESEARCH FUND ASSOCIATION, 1938

THE cause of epidemic dropsy has for long been the subject of intensive research in the School of Tropical Medicine, and the All-India Institute of Hygiene and Public Health, Calcutta. Recent work at both institutions has tended to emphasize the association of mustard oil with the propagation of the disease, a theory which is not new but which had been replaced for a time by two others, namely, those of contact infection from patient to patient and of infection carried through rice damaged by unfavourable conditions of storage.

The studies suggest that the offending factor is the seed of a plant, *Argemone mexicana*, which appears to be widely distributed and to be often present as a weed in mustard plant fields. Its seeds are harvested with mustard seeds and argemone oil is also expressed with mustard oil without the manufacturers being aware of such adulteration.

In some areas, such as the Punjab and the North-West Province, cholera appears only at intervals of years, in certain parts of Bengal it starts almost regularly at the same season every year. An investigation into the causes is complicated by the fact that, apart from the true organism responsible for the disease, numerous other allied organisms exist in water supplies. A differentiation of the characteristics of the true cholera vibrio from its allies and the formulation of methods of its control are therefore essential.

Considerable success has of late been achieved in these two directions in India, and the researches carried out have received warm appreciation from the International Public Health Office at Paris. In the light of the new knowledge, a field investigation is now being undertaken in Bengal, and it is hoped that the results of this enquiry will enable preventive measures to be taken with greater success.

Malaria investigations, both in the laboratory and the field, have proceeded under the Malaria Institute of India, which is financed by the Indian Research Fund Association. In the Wynaad, Madras, and in the Terai in the United Provinces, research units have been making field studies, and similar investigations are proposed for Orissa along the margin of the Chilka Lake. In Delhi, also, anti-malarial operations were supervised by the Malaria Institute. In addition, expert advice is given to the Provincial Public Health Departments in respect of anti-malarial schemes.

In the Haffkine Institute, Bombay, investigations were continued as to the best conditions under which anti-plague vaccine of high protective value could be manufactured. An anti-plague serum has also been produced for the treatment of patients. The serum has had a limited trial during an outbreak of plague in Bihar, and the results so far recorded suggest that its use reduces mortality.

Cyanogas fumigation for keeping down the rat population has been tried as an anti-plague measure in the Cumbum Valley, Madras, and the conclusion reached that fumigation every quarter consistently for a few years may reasonably be expected to eradicate the disease.

A statistical survey of leprosy has been carried out in a group of 42 villages. While the gross incidence of the disease was found to be 4.4 per cent in the total population, only 18 per cent among the patients were of the severe lepromatous type. Nearly 80 per cent of the cases gave a history of contact with leprosy patients, the infection being communicated in a third of cases by near relatives, in another third by distant relations, and in the remaining third either by unrelated or by unknown persons. The severe lepromatous form of the disease transmitted infection more quickly than the relatively milder nerve type.

A study has also been made of the influence of skimmed milk as a supplement to the diet of leprosy patients, and it has been found that its administration seems to hasten the recovery of the lepromatous type.

Tuberculosis investigations covered a wide range and included a detailed survey in a jute mill 23 miles from Calcutta employing 5,000 labourers, a study of children in tuberculous homes and an enquiry into the incidence of the infection among medical students and nurses in Lahore. There is a general recognition that the disease is spreading among urban and rural populations owing to industrialization and rapidly increasing transport facilities and the need is felt of defining the extent of infection in different areas and of determining the social, economic, industrial and other factors responsible for its incidence.

The survey of tuberculous homes revealed that tuberculosis was an important cause of morbidity and

mortality among infants and children, a fact not noticeable from public health returns.

The enquiry at Lahore showed that of 434 medical students examined, 53 per cent had had tuberculosis infection at some time or other and that amongst fourth- and fifth-year students, the percentages were as high as 70 and 80 respectively. This does not of course mean that they were active cases of tuberculosis. In the large majority the infection had been overcome by the natural resistance of the body. In fact, only 4.5 per cent showed physical signs of having suffered from active tuberculosis.

In the field of nutrition, simultaneously with basic research, the programme has been made more practical by relating laboratory investigations to the immediate necessity for improving the nutritional standard of the people under present economic conditions. As instances may be mentioned the discovery of a cheap substitute in red palm oil for cod-liver oil to make up the deficiency of vitamin A in the diet, a factor so widely deficient in India, and the demonstration that the use of calcium lactate at a cost of half to one anna per month per child improves its health. Special attention has been paid to diets largely composed of tapioca and it has been shown that the most important defect in such diets is the deficiency of protein.

A study is being made of the effect of the use of highly milled rice on nutrition. It is recognized that as the use of home-pounded rice is rapidly disappearing, a solution of the problem of ensuring consumption of rice in its most nutritive form must be sought along other lines.

Comparison of rice and maize has shown that rice is richer than maize in nicotinic acid, which prevents pellagra. This may explain why rice eaters rarely develop the disease.

Medical men from the provinces and states have been trained to carry the campaign for better nutrition into different parts of India and to educate the people in matters of nutrition.

REPORT OF THE HAFKINE INSTITUTE, BOMBAY, FOR THE YEAR 1938

In general the activities of the Institute remained the same as in previous years. The production of large quantities of prophylactic vaccine, mainly Hafkine plague vaccine, cholera vaccine, typhoid vaccine and antirabic vaccine, and the diagnostic work for the hospitals largely monopolized its limited resources in funds and personnel. An idea of the work involved in the production of vaccines alone can be gained from the fact that 3,411,258 c.c. (i.e., 1,137,086 doses of plague vaccine, 608,506 c.c. of cholera vaccine, 38,269 c.c. of typhoid vaccine and 733,530 c.c. of 5 per cent antirabic vaccine) were issued during the year. Despite the pressure of routine duties most members of the staff were enabled by the generous aid of the Indian Research Fund Association in funds and personnel to carry out valuable researches. For plague and pharmacological researches the Association contributed about Rs. 50,000. Two voluntary workers and a Lady Tata Memorial Scholar also contributed to the research activities of the Institute.

During the year Government sanctioned a valuable addition to the staff. Advantage was taken of the retirement of Rao Bahadur Chitre to engage an entomologist in his place. The services of a noted Indian entomologist, Dr. M. Sharif, who is an authority on fleas, were secured and a department of entomology organized. Since insects play an important role in the spread of disease in the tropics this new department should prove of great value to the health organization of the province, if the staff could be strengthened to enable the Institute to undertake field investigations. The time of the present staff is fully occupied by laboratory bench work and it does not permit the Institute, the only medical research organization of the Province, to play that rôle in health organization which it should by conducting field and other studies on the urgent

health problems of the people, in close association with the Public Health Department. In the 1924 report the then director strongly stressed the value of such an association and advocated the organization of a mobile unit. The need of such a unit is greater than ever, and it is hoped the staff of the Institute will be strengthened to permit of such work being undertaken. How valuable such an association can be was demonstrated by the enquiry undertaken during the year by the Institute into the outbreak of typhoid fever in the city, in association with Municipal Health authorities.

Antiplague serum.—A small outbreak of plague at Bettiah, Bihar, permitted a field trial of the antiplague serum prepared at the Institute to be carried out. A temporary hospital was erected at the place and other facilities provided by the Bettiah Raj and the Bihar Government for which our grateful thanks are due.

The trial lasted from the middle of January to the end of April 1938. One hundred and twenty-four cases of plague were dealt with. Every alternate admission was treated with serum; others were treated with intravenous injections of iodine solution. No selection was made, but during the third week of the trial all patients admitted were treated with serum. Thus 69 patients were treated with serum, and of these 19 died of plague, giving a percentage mortality of 27 per cent. Of the 55 cases treated with iodine injections, 36 died, giving a percentage mortality of 65 per cent. If to these figures we add the figures of a previous trial conducted at Hyderabad with the same serum, we get 94 patients treated with serum, with 24 deaths, and percentage mortality of 25.5. From among 80 controls, there were 50 deaths giving a percentage mortality of 62.5. Clinically the administration of the serum produced very striking results; the general condition of the patients improved very rapidly with the disappearance of toxic symptoms. These results show that we have obtained a serum of a high curative value. The preparation of this serum was made possible by the exact biological methods worked out in this Institute. Animal experiments were designed which closely reproduced the conditions which severe cases of plague present, and serum was tested on such animals. These experiments yielded a clear idea as to the conditions under which the best serum could be obtained. The full significance of these results can be realized only when they are compared with the results obtained with other antiplague sera tried since the beginning of the present pandemic. None of these sera reduced the case mortality below 60 per cent.

Chemotherapy of plague.—Some of the sulphanilamide compounds which have proved to be so valuable in the treatment of streptococcal infection were tested for their curative value in plague infection. For this purpose animal experimental conditions were designed to produce disease approximating to the actual severe cases of plague. The compounds tested, Prontosil and M. and B. 693, showed little or no curative power. Further work is proceeding.

Plague vaccine.—No changes were introduced in the preparation of the plague vaccine during the year. Though the recent researches conducted at the Institute have thrown a flood of light on the problem of the preparation of a plague vaccine, there are still some obscure points to be solved. Exact determinations are being made to compare the protective powers of agar and broth vaccines to see which of the two methods gives the best chance of producing vaccines of uniformly high protective power. Experiments are also being conducted to increase the growth of organism in broth cultures, as the protective power of a broth vaccine incubated at a suitable temperature depends on the number of the organisms growing in the medium.

Serology of plague.—A great deal of work has been conducted to elucidate the phenomena of agglutinin and precipitin reaction and their relation to active immunity in plague, but the results are still very divergent and more work will have to be carried out before any worthwhile conclusion can be drawn.

Enquiry into the outbreak of typhoid fever in the City of Bombay

During the year there was a sudden increase in the incidence of typhoid fever in the city and the Institute was asked to investigate the sources and mode of this outbreak in collaboration with the Municipal Health authorities. The Institute assumed responsibility for (1) laboratory diagnosis of cases by sending out an officer to take samples of blood and other material on receipt of a call from any medical practitioner or hospital and (2) investigation into the source or sources of infection and the mode of spread of the disease.

Cases.—From the 25th of June to the end of the year, the Institute examined 398 cases, out of which 234 proved to be cases of typhoid fever and 16 cases of paratyphoid A. The fact which requires to be stressed here is that this laboratory aid in the diagnosis of cases, given absolutely free of charge to medical practitioners, improved considerably the situation regarding the notification of this disease in the city. For the five-year period previous to the present enquiry 1,959 attacks and 1,349 deaths had been notified from typhoid. These figures give a very improbable case mortality of 69 per cent while the present enquiry yields among the definitely diagnosed cases, the very likely figure of 9.3 per cent case mortality, showing that in previous years roughly 1 attack out of every 6 occurring in the city was notified. It was obvious that the medical practitioners appreciated the help given to them; they were willing to make use of it, leading to a much higher percentage of notification. It is very gratifying to note that Government is devising a permanent scheme to make available to medical practitioners such laboratory aid in the diagnosis of their cases, free of charge.

Sources and mode of spread.—Though the water supply of the city was not found to be up to the required standard of purity, it was not held responsible for the typhoid outbreak. Largest number of cases occurred in unsewered parts of the city where basket privies were in use. Some sewage from the areas was allowed to flow into the open drains. This, coupled with a great increase in the number of flies in the area, explained part of the trouble. Direct contact due to overcrowding in tenement houses and the refusal of patients to go to the infectious diseases hospital was another factor in the spread of the disease. No articles of food examined were incriminated, but the carrier problem could not be tackled for lack of co-operation on the part of the public.

Studies on the synthetic anti-malarial drugs, plasmoquine and atabrin, were continued. The observation reported last year that the placenta filtered out plasmoquine and prevented large quantities of the drug from entering the foetal circulation, was further confirmed by the actual measurement of the concentration of plasmoquine in the maternal and foetal blood simultaneously after giving large doses of the drug to the mother. It was further shown that therapeutic doses of plasmoquine given to pregnant experimental animals did not in any way affect the litters given by the animals. These studies show that this drug can be safely used during pregnancy.

The fate of plasmoquine and atabrin in the body has been studied. Plasmoquine is largely destroyed by the liver and atabrin was retained by reticulo-endothelial cells. A very important observation regarding the formation of acetylcholine was made. It was found that chiefly nerve cells were responsible for its formation.

Some studies had shown that the average hæmoglobin content of blood of Indian normal subjects tallied exactly with similar averages worked out in America for white American subjects. These averages were 15.37 g. and 12.99 g. per 100 c.c. of blood for men and women respectively. This observation suggested the possible existence of a hæmoglobin constant. Nineteen subjects have so far been examined and an attempt is being made to find if there is a definite ratio between hæmoglobin content and some such unit as body surface.

The power of the kidney to eliminate urea from the blood stream is employed as a measure of renal function for clinical purpose. Moller, MacIntosh and Van Slyke's blood urea clearance test worked out on American subjects is usually employed for the purpose. It was noticed in the course of clinical work that in the case of normal Indian subjects while the blood urea content is within the same limits as that of American subjects the urea content of urine of normal Indian subjects is about half of American subjects. This raises an interesting issue whether the formula on which the urea clearance test is based applies to Indian subjects. This subject is being studied.

Four more antirabic treatment centres were opened during the year, making a total of 87 in the Province and in the neighbouring areas. The opening of these centres is a real boon to the public. These centres enable the public to get the antirabic treatment without having to make unnecessarily long journeys.

Demand for the antirabic treatments showed a further rise during the year. 11,479 treatments were issued as compared with 9,715 treatments issued last year.

THE REPORT ON THE PUBLIC HEALTH ADMINISTRATION OF THE PUNJAB FOR THE YEAR 1937

THE population of the province continues to increase, the estimated mid-year population for 1937 being 26,000,000 as against 25,500,000 in 1936. As the director states, this annual increase raises questions with respect to standards of living and the economic development of the province which deserve consideration.

Fevers.—The number of deaths in the province during the year from all causes was 556,000, of which 376,000 were recorded as deaths from fever as compared with 374,000 in 1936. The term 'fever' includes a considerable group of diseases of which the predominant symptom is fever, e.g., malaria, enteric, tuberculosis and influenza, and as the director explains, reports as to the diseases which may have caused death in particular cases cannot be regarded as accurate. Inaccuracies are in fact to a large extent inevitable in the rural area where there are at present few doctors to diagnose the exact nature of a disease.

Smallpox.—The province is never entirely free from smallpox. The disease does not as a rule assume serious epidemic form but it shows a tendency to increase every few years; there was, for example, a severe epidemic in 1932, and a further epidemic, though of lesser intensity, has to be recorded in 1937. In 1936 there were 6,000 cases with 2,500 deaths, and at the same time three and a half million vaccinations and revaccinations were carried out. In 1937 there were 10,000 cases with 4,000 deaths, and five and a half million vaccinations and revaccinations were carried out. During the two years therefore the number of persons vaccinated was eight millions, which is nearly a third of the total population of the province but the disease showed a further increase in 1938 though exact figures for that year are not yet available. As regards the 10,000 cases which occurred in 1937, the number of villages infected was 1,350 as compared with 1,000 in 1936. Of the 4,000 deaths in 1937, 1,500 were of infants below one year of age, and 1,800 of children between the ages of 1 and 10. The figures indicate that still greater effort is needed to ensure the vaccination of infants as soon as possible after birth. Under the present act local bodies are only empowered to make primary vaccination compulsory; the director has, however, submitted proposals for an amendment of the law so as to enable any local body which may wish to do so to make revaccination compulsory, and these are being examined.

Cholera.—Cholera is a disease of which a number of cases occur every year, and when streams or wells are infected it sometimes spreads with great rapidity. In 1936 there were 2,700 cases with 1,700 deaths. It is, however, satisfactory to note that during 1937 there were only 184 cases with 105 deaths. As usual the infection was in an appreciable number of cases

imported from outside the province, particularly from Hardwar.

Plague.—Plague is a disease from which the province has suffered much in the past. Wherever the disease has appeared mass inoculation has been undertaken; at the same time the public health department have for many years conducted a campaign against rats in areas in which the disease has constantly appeared. In 1936, only 153 deaths from plague were recorded, and in 1937 (for the first time after 40 years) no cases at all occurred in the province though 4 were imported from outside. The director states that the factors which have caused this cannot be determined.

Tuberculosis.—Very little is known about the incidence of tuberculosis except that it is believed to be considerable. The people as a rule are not inclined to take notice of the disease in the early stages when it may be curable, and death when it occurs may be recorded as from fever or one of the respiratory diseases. It is noted that during 1937, 5,000 deaths in the province were returned as on account of tuberculosis compared with 4,800 in 1936, but the true figure is probably higher. While what it has seemed possible to do to deal with the tuberculosis question has been done in the past, no concerted attack has been instituted against the disease, partly on account of the magnitude of the question and the difficulty of knowing where to make a beginning. A concerted attack is however now about to be launched on an all-India basis under the auspices of Her Excellency the Marchioness of Linlithgow's Tuberculosis Association of India with its affiliated provincial branches.

Leprosy.—A leprosy survey has been proceeding for some years, and has now been completed in 18 out of the 29 districts. Two thousand cases have so far been observed, and the number of special clinics, which serve as both treatment and propaganda centres, is now 106. The five leper homes continued their excellent work, ministering to 646 inmates of whom however only a hundred are Punjabis. Two hundred and sixty-four doctors in the province have now received special training in the diagnosis and treatment of leprosy.

Hookworm.—A hookworm survey has also been in progress for some years, and has now been completed in 20 districts. In some as many as 30 per cent of the persons examined were found to be infected, and treatment is now being administered partly at the local hospital or dispensary and partly by special treatment units. The disease would almost entirely disappear if latrines conforming to hygienic principles were to be generally adopted, or alternatively if all persons wore shoes.

Sanitation.—The standard of sanitation in towns remains low. In the larger municipalities which employ a whole-time health officer, arrangements are on the whole as satisfactory as can be expected, regard being had to the insanitary habits of many of the people. In the smaller towns, however, which have not the funds either for a health officer or for roadside drainage, conditions are usually deplorable, and, as the director states, the 3,000 cases of enteric with a thousand deaths reported from urban areas are almost certainly an underestimate.

Before public health conditions in a village can be regarded as satisfactory, the minimum that is necessary is that the water supply should be safe from pollution, that the inhabited area should be properly drained, and that there should be a system for the regular removal of refuse to a distance; out of the 35,000 villages in the province only 1,960 attain this standard at present but improvement may be expected as education spreads. Six thousand new hand-pumps are reported to have been installed in villages during the year while 450,000 feet of masonry drains were laid down compared with 260,000 feet in 1936. It is also reported that 600 village sanitary committees were formed during the year, and though the director notes that few seem to have functioned it is encouraging to see that villagers themselves in different districts subscribed over a lac of rupees during the year for sanitary works and in addition contributed labour and material.

Maternity and child welfare.—It is probable that there is now no urban area in which there is not a sufficiency of trained *dais*, and municipal and small town committees are being encouraged to frame by-laws prohibiting practice by untrained women. In the rural area, however, there is still a shortage of trained *dais*. The women are trained at health centres of which during the year under report there were 89 with 128 sub-centres, the centres being under the charge of lady health visitors who are trained in the Punjab Health School at Lahore at the rate of about 14 a year. The demand for lady health visitors exceeds the supply with the result that it has not been possible to open further centres for which funds existed. About 2,000 trained *dais* are known to be practising in the province, while another 2,000 are at present under training.

Inspection of schools and school children.—The medical inspection of school children is still in the experimental stage, and here again the difficulty in arranging for defects noted, to be regularly treated, is for a number of reasons considerable. During 1937 the further experiment was started of supplying milk in certain schools to those children who being sickly or undernourished may be most in need of it.

THE THIRD ANNUAL REPORT OF THE INDIAN INSTITUTE FOR MEDICAL RESEARCH, CALCUTTA, FOR 1937-38

THE third Annual Report of the Indian Institute for Medical Research shows that this Institute is receiving a much greater measure of sympathy and recognition both at home and abroad.

Although our financial difficulties still persist, there is no lack of devotion and earnestness on the part of our workers who alone have made it possible for the Institute to carry on its work fruitfully and efficiently.

In the department of bacteriology, the programme of researches included the work on the immunity problems connected with cholera and typhoid, which was continued throughout the year under review. The relation of streptococcus isolated from the throat with that isolated from puerperal fever was investigated and the result showed that the number of hæmolytic streptococcus obtained from throat swab of the maternity cases suffering from puerperal fever was very small.

In the department of protozoology, further studies on the problem of protozoal cultivation and protozoal immunity are being made with special reference to malaria, amebiasis and leishmaniasis. The results so far achieved appear to be very encouraging.

The department of biochemistry and nutrition put on the forefront of its programme of work during the year the problem of a nutritional survey of Indian food-stuffs and dietaries.

What is most gratifying to note is that of late public interest has steadily awakened in researches into food-stuffs and dietaries undertaken at different laboratories in the country, including ours. The importance of nutrition as a paramount factor in the improvement of national health needs no emphasis and we feel that the institute's work in this direction has the support of the public of India.

A large number of common food-stuffs and dietaries of Bengal have been investigated from various aspects at the institute. It has been known for some time that the type of food commonly consumed by urban populations in Bengal is not calculated to afford adequate nutrition especially during childhood and adolescence and also during pregnancy and lactation. Our biological investigations have revealed that the ordinary diet taken by an average family in Calcutta or in an average students' hostel is partially deficient in vitamins A and B-complex. The work at the institute reveals that the average diet is not only deficient in these vitamins, but also lacks to a considerable degree the very important body-building minerals,

Enquiry into the outbreak of typhoid fever in the City of Bombay

During the year there was a sudden increase in the incidence of typhoid fever in the city and the Institute was asked to investigate the sources and mode of this outbreak in collaboration with the Municipal Health authorities. The Institute assumed responsibility for (1) laboratory diagnosis of cases by sending out an officer to take samples of blood and other material on receipt of a call from any medical practitioner or hospital and (2) investigation into the source or sources of infection and the mode of spread of the disease.

Cases.—From the 25th of June to the end of the year, the Institute examined 398 cases, out of which 234 proved to be cases of typhoid fever and 16 cases of paratyphoid A. The fact which requires to be stressed here is that this laboratory aid in the diagnosis of cases, given absolutely free of charge to medical practitioners, improved considerably the situation regarding the notification of this disease in the city. For the five-year period previous to the present enquiry 1,959 attacks and 1,349 deaths had been notified from typhoid. These figures give a very improbable case mortality of 69 per cent while the present enquiry yields among the definitely diagnosed cases, the very likely figure of 9.3 per cent case mortality, showing that in previous years roughly 1 attack out of every 6 occurring in the city was notified. It was obvious that the medical practitioners appreciated the help given to them; they were willing to make use of it, leading to a much higher percentage of notification. It is very gratifying to note that Government is devising a permanent scheme to make available to medical practitioners such laboratory aid in the diagnosis of their cases, free of charge.

Sources and mode of spread.—Though the water supply of the city was not found to be up to the required standard of purity, it was not held responsible for the typhoid outbreak. Largest number of cases occurred in unsewered parts of the city where basket privies were in use. Some sewage from the areas was allowed to flow into the open drains. This, coupled with a great increase in the number of flies in the area, explained part of the trouble. Direct contact due to overcrowding in tenement houses and the refusal of patients to go to the infectious diseases hospital was another factor in the spread of the disease. No articles of food examined were incriminated, but the carrier problem could not be tackled for lack of co-operation on the part of the public.

Studies on the synthetic anti-malarial drugs, plasmoquine and atabrin, were continued. The observation reported last year that the placenta filtered out plasmoquine and prevented large quantities of the drug from entering the foetal circulation, was further confirmed by the actual measurement of the concentration of plasmoquine in the maternal and foetal blood simultaneously after giving large doses of the drug to the mother. It was further shown that therapeutic doses of plasmoquine given to pregnant experimental animals did not in any way affect the litters given by the animals. These studies show that this drug can be safely used during pregnancy.

The fate of plasmoquine and atabrin in the body has been studied. Plasmoquine is largely destroyed by the liver and atabrin was retained by reticulo-endothelial cells. A very important observation regarding the formation of acetylcholine was made. It was found that chiefly nerve cells were responsible for its formation.

Some studies had shown that the average hæmoglobin content of blood of Indian normal subjects tallied exactly with similar averages worked out in America for white American subjects. These averages were 15.37 g. and 12.99 g. per 100 c.c. of blood for men and women respectively. This observation suggested the possible existence of a hæmoglobin constant. Nineteen subjects have so far been examined and an attempt is being made to find if there is a definite ratio between hæmoglobin content and some such unit as body surface.

The power of the kidney to eliminate urea from the blood stream is employed as a measure of renal function for clinical purpose. Moller, MacIntosh and Van Slyke's blood urea clearance test worked out on American subjects is usually employed for the purpose. It was noticed in the course of clinical work that in the case of normal Indian subjects while the blood urea content is within the same limits as that of American subjects the urea content of urine of normal Indian subjects is about half of American subjects. This raises an interesting issue whether the formula on which the urea clearance test is based applies to Indian subjects. This subject is being studied.

Four more antirabic treatment centres were opened during the year, making a total of 87 in the Province and in the neighbouring areas. The opening of these centres is a real boon to the public. These centres enable the public to get the antirabic treatment without having to make unnecessarily long journeys.

Demand for the antirabic treatments showed a further rise during the year. 11,479 treatments were issued as compared with 9,715 treatments issued last year.

THE REPORT ON THE PUBLIC HEALTH ADMINISTRATION OF THE PUNJAB FOR THE YEAR 1937

THE population of the province continues to increase, the estimated mid-year population for 1937 being 26,000,000 as against 25,500,000 in 1936. As the director states, this annual increase raises questions with respect to standards of living and the economic development of the province which deserve consideration.

Fever.—The number of deaths in the province during the year from all causes was 556,000, of which 376,000 were recorded as deaths from fever as compared with 374,000 in 1936. The term 'fever' includes a considerable group of diseases of which the predominant symptom is fever, e.g., malaria, enteric, tuberculous and influenza, and as the director explains, reports as to the diseases which may have caused death in particular cases cannot be regarded as accurate. Inaccuracies are in fact to a large extent inevitable in the rural area where there are at present few doctors to diagnose the exact nature of a disease.

Smallpox.—The province is never entirely free from smallpox. The disease does not as a rule assume serious epidemic form but it shows a tendency to increase every few years; there was, for example, a severe epidemic in 1932, and a further epidemic, though of lesser intensity, has to be recorded in 1937. In 1936 there were 6,000 cases with 2,500 deaths, and at the same time three and a half million vaccinations and revaccinations were carried out. In 1937 there were 10,000 cases with 4,000 deaths, and five and a half million vaccinations and revaccinations were carried out. During the two years therefore the number of persons vaccinated was eight millions, which is nearly a third of the total population of the province but the disease showed a further increase in 1938 though exact figures for that year are not yet available. As regards the 10,000 cases which occurred in 1937, the number of villages infected was 1,350 as compared with 1,000 in 1936. Of the 4,000 deaths in 1937, 1,500 were of infants below one year of age, and 1,800 of children between the ages of 1 and 10. The figures indicate that still greater effort is needed to ensure the vaccination of infants as soon as possible after birth. Under the present act local bodies are only empowered to make primary vaccination compulsory; the director has, however, submitted proposals for an amendment of the law so as to enable any local body which may wish to do so to make revaccination compulsory, and these are being examined.

Cholera.—Cholera is a disease of which a number of cases occur every year, and when streams or wells are infected it sometimes spreads with great rapidity. In 1936 there were 2,700 cases with 1,700 deaths. It is, however, satisfactory to note that during 1937 there were only 184 cases with 105 deaths. As usual the infection was in an appreciable number of cases

If that is the case what are we all arguing about? Where is the deception, criminal or venial? Unless of course the wrong prescription is written on the bottle, but it is a most unusual procedure to write any prescription on the bottle that is given at a government dispensary.

But is it sufficient to cure the fever? There are other statements in his letter which make one doubt this. His vivid pen-picture of the disgruntled tribesman 'looking forlornly at a small quantity of liquid at the bottom of a large bottle' contrasted with the happy one with a full bottle (which might well have been illustrated by a marginal drawing of the local editions of Mr. Can and Mr. Can't) suggest at least a four-fold dilution. The dosage prescribed in local 'pharmacopœias' is not usually a wasteful one, and, if the amount is reduced to one-fourth of this, it will certainly fail to cure the fever in a very large number of cases. We have not quite followed the argument in the fifth paragraph of this letter, but the 'totally inadequate dose of quinine' he mentions seems to apply to the dose which he has already described as being 'sufficient to cure the fever'.

However, on balance this letter seems to indicate that, as a matter of general practice, from the government dispensaries in Waziristan a mixture is issued, which, though it purports to be a cure for malaria, will in actual fact fail to cure a large number of those who take it, who rely on it for curing their malarial attack, and whose subsequent opinion of 'western' medicine is dependent on their personal experience.

The next point on which we are at variance with our correspondent is on the subject of malarial treatment. Is the tribesman really so ignorant in refusing to continue taking quinine 'long after the disappearance of fever'? There is at the present day a school of thought which recommends a minimal course of quinine, and the weight of world opinion on this subject is against anything longer than a seven-day course of any anti-malarial drug as a curative procedure.

Now to take the offensive—though criticism of the individual dispenser was never in our minds and though the word 'fraud' was never meant to be applied to his attempts to make the best of a bad state of affairs, we are certainly prepared to apply a much stronger word to a system which condones and even necessitates this degradation of scientific medicine.

We venture to make only one suggestion why does our correspondent use quinine when cinchona febrifuge (totanquina standard) costs half as much, and is, at the lowest estimate, 95 per cent as efficacious?—EDITH, I. M. G.J

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL B. Z. SHAH returned from leave and resumed charge of the duties of Civil Surgeon, Belgaum, with effect from the forenoon of 25th September, 1939.

Lieutenant-Colonel Jelal M. Shah, M.B.E., returned from leave and is placed on general duty at the J. J. Hospital, Bombay, with effect from the forenoon of 25th September, 1939.

Lieutenant-Colonel A. H. Harty returned from leave and resumed charge of the duties of Civil Surgeon and Superintendent, B. J. Medical School and Mental Hospital, Ahmedabad, with effect from the forenoon of 30th September, 1939.

On having been recalled from leave Lieutenant-Colonel P. A. Dargan resumed charge of the Office of Civil Surgeon, Amritsar, on the forenoon of the 4th October, 1939, relieving Major J. J. Beausang.

Lieutenant-Colonel N. S. Jatar, C.I.E., D.S.O., Inspector-General of Prisons, C. P. and Berar, has been appointed to officiate as Inspector-General of Civil Hospitals, C. P. and Berar, in addition to his own duties from 6th October, 1939.

Lieutenant-Colonel E. W. O'G. Kirwan, C.I.E., on return from leave *ex-India*, is reappointed to be Professor of Ophthalmology, Medical College, Calcutta, with effect from the 29th September, 1939.

Major J. J. Beausang was reposted as Civil Surgeon, Sargodha, with effect from the forenoon of the 9th October, 1939, relieving Captain D. W. Taylor.

Major F. H. A. L. Davidson, on general duty in the Medical College Hospital, Calcutta, is appointed to be Civil Surgeon, Burdwan, *vice* Dr. Keshab Chandra Sen Gupta.

Major E. G. Montgomery, on general duty in the Medical College Hospital, Calcutta, is appointed to be Civil Surgeon, Jalpaiguri, *vice* Major G. B. W. Fisher.

Previous notifications are hereby cancelled. Major G. B. W. Fisher made over charge of the Jalpaiguri Jail to Dr. Ajit Kumar Dutta on the forenoon of 30th September, 1939.

Major W. Aitchison, M.C., has on recall from leave, been posted as Civil Surgeon, Allahabad, *vice* Major R. A. Wesson.

Major R. A. Wesson has been transferred from Allahabad to Gorakhpur, *vice* Captain A. B. Guild.

Major F. H. Whyte is appointed to the post of Civil Surgeon, New Delhi, with effect from the forenoon of the 9th October, 1939.

Major K. H. A. Gross, M.C., an Officiating Agency Surgeon, on return from leave, is appointed as Agency Surgeon in Bundelkhand, with effect from the afternoon of the 30th September, 1939.

Captain C. B. Miller has been appointed as Resident Medical Officer at the J. J. Hospital, Bombay, with effect from the afternoon of 28th September, 1939.

Captain R. de Solderhoff returned from leave and received charge of the duties of Resident Medical Officer, St. George's Hospital, Bombay, with effect from the forenoon of 28th September, 1939, from Captain C. B. Miller, transferred.

Captain D. W. Taylor, on relief by Major J. J. Beausang, was placed on special duty at the Civil Hospital, Sargodha, with effect from the forenoon of the 9th October, 1939, as a member of the leave reserve.

Captain F. W. Allinson, on general duty in the Medical College Hospital, Calcutta, is appointed to be Civil Surgeon, Bakarganj, *vice* Rai Dr. B. B. Hazra Bahadur.

Captain A. B. Guild has been transferred from Gorakhpur to Saharanpur.

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the following Officers of the Indian Medical Service with effect from the dates mentioned against their names:—

Government of India

Major S. S. Bhatnagar. Dated 26th June, 1938 (afternoon).

Major Jaswant Singh. Dated 11th July, 1938 (afternoon).

Major M. K. Kelavkar, M.B.E. Dated 20th October, 1938 (afternoon).

Major W. F. Cooper. Dated 9th November, 1938 (afternoon).

Bombay

Captain L. Feinhols. Dated 5th August, 1938 (afternoon).

Bengal

Captain J. W. D. Goodall. Dated 18th September, 1938.

Major E. A. R. Ardeshir. Dated 26th November, 1938.

Punjab

Captain F. V. Stonham. Dated 27th September, 1938.

Bihar

Captain W. B. Stiver. Dated 28th August, 1938.
 Captain F. W. Whiteman. Dated 8th September, 1938.

Central Provinces

Captain M. Sendak. Dated 29th July, 1938.
 Captain F. C. Leach. Dated 6th December, 1938.

Orissa

Captain J. W. Bowden, M.B., B.Ch. (Dub.), D.T.M. & H. (Lond.), I.M.S. Dated 11th October, 1938.

The Secretary of State for India has sanctioned the reversion to military employment of the following Officers of the Indian Medical Service (Civil) with effect from the dates mentioned against their names:—

Government of India

Major W. F. Cooper. Dated 30th December, 1938 (afternoon).

Bihar

Captain W. B. Stiver. Dated 12th November, 1938 (afternoon).
 Captain F. W. Whiteman. Dated 5th December, 1938 (forenoon).

LEAVE

Major-General E. W. C. Bradfield, C.I.E., O.B.E., K.H.S., Director-General, Indian Medical Service, is granted leave on average pay for 1 month and 1 day and in continuation leave on half-average pay for 4 months and 6 days, with effect from the afternoon of the 29th September, 1939.

Lieutenant-Colonel S. Nag, late Civil Surgeon, 24-Parganas, is granted leave for 3 months on medical certificate from the 1st October, 1939.

PROMOTIONS

The undermentioned Officer is granted the local rank of Major-General, without effect on pay and pension, whilst officiating as Director-General, Indian Medical Service:—

Colonel G. G. Jolly, C.I.E., V.H.S.

Majors to be Lieutenant-Colonels

R. W. H. Miller. Dated 9th October, 1939.
 P. A. C. Davenport. Dated 22nd October, 1939.

Captains to be Majors

F. M. Khan. Dated 3rd October, 1939.
 D. Datt. Dated 10th October, 1939.

Captain to be Major (provl.)

M. G. Saincer. Dated 12th October, 1939.

RETIREMENTS

Colonel Sir A. J. H. Russell, C.B.E. Dated 30th August, 1939.

Brevet-Colonel F. A. Barker, O.B.E., C.I.E. Dated 16th October, 1939.

Note

EPHYNAL 'ROCHE'

A PURE SYNTHETIC VITAMIN E (ANTI-STERILITY VITAMIN)

EXISTENCE of a fertility vitamin (vitamin E) was first suggested by Evans in 1922. It was found to be present mainly in plant oils, especially in wheat-germ oil and was isolated and named by him as 'tocopherol'. Its constitution and active principle were elucidated by Karrer and his collaborators. The biological standardization and perfection of the synthesis on a technical scale followed in Roche Laboratories and synthetic vitamin E is now marketed as 'd.l.a.tocopherol acetate' under the trade name of Ephyнал 'Roche'.

Rats fed on diets deficient in vitamin E are unable to bear normal young; they absorb the foetus during gestation. Exhibition of 2 mg. of Ephyнал shortly before or just after impregnation was sufficient to prevent abortion and normal young was born. Lack of vitamin E in male animals brings about degeneration of genital epithelium which leads to oligospermia, azoöspemia and finally to complete sterility. Favourable results have followed administration of vitamin E to women who have previously had miscarriage or premature birth from no accountable cause and in many cases they gave birth to normal children. Formerly clinicians used to rely on concentrate of vitamin E. Synthetic vitamin E in the shape of Ephyнал 'Roche' now makes accurate and extensive clinical investigation possible. Ephyнал is indicated in cases of habitual abortion, premature and still-births occurring without discoverable cause. Threatened abortion, uterine contraction and hæmorrhage in the early stage of pregnancy have also been averted in some cases. Certain conditions of sexual underdevelopment and the sterility, delayed menarche, oligo- and amenorrhœa associated therewith are benefited by Ephyнал, which not only ensures development of embryo during pregnancy but also normal growth and function in the new-born. Owing to its favourable action on male reproductive organs Ephyнал is recommended in impotence. Dosage is usually 1 to 2 gm. of vitamin E for the entire pregnancy or 1 to 2 tablets of Ephyнал daily. In case of threatened abortion the dose may be increased from 5 to 10 times this quantity and continued for a week or two.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

Subscribers who so desire may have their copies packed flat in a strong envelope. The extra charge per annum is Re. 1-8 which should be added to the subscription. The envelopes are strongly made, and the *Gazette* is not folded, nor creased, in transit.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in the *Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors, and of the publishers.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.
